***Document: U0.00.01***

***Guide reading of the documentation of Use***

***Summary:***

*This document has as an ambition to propose an assistance to a first access to the contents of documentation of Aster use.*

*One describes, initially, the principles which govern the organization space time of documentation Aster in general and the parts of this documentation which concern the user in particular. In fact, one will see that the user (not developer) will not draw only his documentary resources in the Handbook of Use.*

*One suggests a guide (way) of reading while trying to put itself in the state of mind of an initial user as well for the handling of the code as for navigation in its documentation.*

*Finally one formulates in the questions and answers mode of the considerations on the questionings of which is the object documentation Aster, by locating them in the problems of the documentary cover of a large product software.*

*The reader wishing to go directly to the active part of this document will go to [§2] and [§3].*

*1 Documentation*

*Code\_Aster: organization and access*

*Before beginning navigation as a whole from the documentation of Code\_Aster, the user must to have well at the head the organization space time of the documentary territory in which it will*

*evolve/move and*

*the aspects Quality assurance of the documentary objects Aster. The code grows rich, changes all weeks, its documentation, unfortunately, not. Nevertheless, a good apprehension of structuring of the documentary ground, of the nature even of the objects that one meets there and the laws of*

*their evolution in time should make it possible the user not to be exceeded by the sum and the scatter of required knowledge, has minimum, to launch its first Aster calculation.*

**1.1**

*A logical cutting in Handbooks: the ARDUV*

*The technical documentation of Code\_Aster comprises:*

- five handbooks,*
- a whole of other documentary objects which come in complement from documentation basic technique Ci above.*

*Instruction manual*

**U**

*Instructions of the orders, structures of data*

*users, examples of use*

*Handbook of Reference*

**R**

*Formulation of the modelled phenomena, methods of analysis, algorithms numerical*

*Data-processing handbook of Description D*

*Structures of data, algorithms, architecture, environment*

*Handbook of Validation*

**V**

*Elementary test probes in all the fields of modeling*

*Handbook of Administration*

**With**

*Quality plan, procedures of development and of maintenance, engagements of services, versionnement*

*The other documentary objects consist of a series of articles, presentations of functionalities code (for example, the collection of the newspaper ASTER echoes, plate of presentation of fields of modeling of the code, transparencies of conferences on functionalities of the code, presentations of industrial studies, etc). These objects, whose documentary vocation is not precisely directed towards the technique of use of Code\_Aster are accessible in various headings of Internet site of Code\_Aster.*

*The basic handbooks of the Aster user are the Instruction manual, the Handbook of Reference and it Handbook of Validation. The Instruction manual frequently returns to the Handbook of Reference. Data-processing handbook of Description is reserved for the developers, in theory it does not relate to them users; it is the same for the Handbook for Administration. An exception of size for it the last: the user has access to the Cards Quality and Cards Followed Quality which indicate to him for poured exploitation and of development of the code which are the evolutions, identified errors corrected or not and solutions of skirting.*

*The handbook is subdivided in ten named parts (numbered from 0 to 9), the parts in booklets also named (00 to 99), booklets in documents (00 to 99).*

*Instruction manual*

*COURTEOUS Mr., Mr. BOIN, J.M. PROIX Key*

*:*

*U0.00.01-E Page*

*: 3/12*

*1.1.1 The documentary key Aster*

*A document is located in the documentary space of the handbooks by a documentary key:*

*Manuel\_Partie.Numéro\_du\_fascicule.Numéro\_du\_document-Indice*

*Example of a documentary key: U1.02.00-B*

*Naturally, one indicates a document by his documentary key. For reasons of convenience two classes of documents are as indicated by the Aster function as it document:*

- *documents of the instructions of the orders (Instruction manual) indicated by name of the documented order,*
- *documents of description of the elementary cases test dedicated to the validation of the code (Handbook of Validation) indicated by the code of the case test.*

### *Examples:*

*U4.43.01-F documents order DEFI\_MATERIAU, one will say document DEFI\_MATERIAU.  
V7.90.04-A documents the case test of thermomechanics HNSV100: Thermoplasticity in traction simple, document HNSV100 will be said*

*Other documentary objects that those contained in the handbooks are not affected key it has just been question.*

### *1.1.2 Version of the code versus index of the document*

*Each technical document of the handbooks increases in heading a certain number of indications bibliometric (names of the handbooks and booklets of membership, titrates, the name of () the author, key, summary, version of the code). Among those, three deserve a detailed attention because they touch with the Quality assurance of the code and the update of the documents:*

- *the Version of the code concerned with the document,*
- *the index of the document,*
- *the date carried by the document.*

### *1.1.3 With which version of the code applies the document?*

*In top and on the right the top of page of the document the n° of version appears and, possibly, of under version of the code for which the document applies. For example:*

- *5.0 documentation valid for all version 5 (and the following ones if there is no setting with day),*
- *6.3 valid documentation starting from under-version 6.3 and for the following ones; documents which carry former numbers (6.0, 6.1, 6.2) are not updated at the time of the introduction of a under-version.*

*There is always, at least, 2 versions of the code available. The version known as of Exploitation, currently version 6, validated and qualified (thus under AQ). It is the version of exploitation which must be used for the studies under AQ. The version of Development (currently version 7), provided with last innovations, not yet validated version nor qualified. The Aster user must constantly*

*to know which are officially the version of exploitation and the version of development. These versions evolve/move every 2 years (increment of the number of version). With each startup of a version and of under versions of exploitation or development, are brought into service a Card Quality and Cards Followed Quality. These documents index, for a version or under version given, the list fields (functionalities) qualified and remarks and restrictions on the qualified fields. These cards (which are documents resulting from the File of Administration) are available on the waiter in the heading Use/Quality.*

*:*

*U0.00.01-E Page*

*: 4/12*

#### *1.1.4 What represents the index of a document?*

*It traces the evolution of the document in time and known as if the document is under AQ or not. In theory, with*

*each update of a document, this one follows an internal circuit of validation which qualifies the document*

*within the meaning of the quality assurance of the code. The indices of the documents under AQ are literal (A, B, C, D, etc).*

*For example, in the version of exploitation of the code at a given time, the document of use of order DEF1\_MATERIAU carries key U4.43.01-F, the code letter F indicates that the document is under AQ and which it was updated under AQ five times. At the same time, document U4.43.01-G1 is also published; it corresponds to an update not AQ and applies to the version of development.*

### ***1.1.5 Date from the document***

***It is the date of qualification of the document. It will be noted, for example, that the most up to date documents***

***relate to the use of the orders of the version of current exploitation, as well as modelings and structures of data of the result type of this version. It is documentary leading policy of the code which wants that the release of a version of exploitation is immediately followed edition of the documents of which it has just been question.***

### ***1.2***

***To reach the documentation of use of Code\_Aster***

***The technical documentation of Use of Code\_Aster is a subset of its documentation general.***

#### ***1.2.1 It is an entirely electronic documentation....***

***... since the 07/2000. Old documentations paper in the form of white sorters with rings with the A4 format are out-of-date and do not have to be used any more. It was requested from all the users***

***Aster at the time of the introduction of the electronic form to destroy all these sorters.***

***Documentation is published on Internet site of the code to the address:***

***<http://www.code-aster.org/>***

***Periodically (approximately every 15 days), electronic documentation grows rich by new documents or of updates of old documents.***

***Internet site is the subject of a data-processing description [D9.09.01].***

***Instruction manual***

**COURTEOUS Mr., Mr. BOIN, J.M. PROIX Key**

:

**U0.00.01-E Page**

**: 5/12**

**1.2.2... Which also exists in form paper**

**Every 2 years (at each release of a new version of exploitation), handbooks paper of pocket documentation of the code are published. Those are a photograph at one time given of electronic documentation. For consultation of these handbooks of pocket, it is necessary to have the reflex of to ensure itself of the n° of version of the code that they document, and the date which they carry.**

**One will order the shape paper of the Reference and instruction manuals (several volumes each one) with code-aster@edf.fr.**

**It is nevertheless possible to print locally the electronic document posted entirely or in part.**

**1.3**

**General presentation of the documentary resources of use**

**In fact the basic user will draw his documentary resources in 3 handbooks, in this order:**

**· Manuel U of which it must have the structuring at the head well**

**Documented functionalities**

**Parts of handbook**

**U4: basic commands**

**Instructions of the orders**

**U7: orders of exchanges of data with other software**

**Structures of user data**

**U5**

**Characteristics of modelings**

**U3**

**Note of use of modelings**

**U2**

**Access to the code**

**U1**

- **Manuel R:** *finite elements, the formulation of modelings of the phenomena*
- **Manuel V:** *the cases test of validation*

## 2

### **Making of contact**

*There is obviously no question exhaustively of reading all the instruction manual. In May 2003, it comprise 310 documents (of which 200 relate to the use itself of the orders) which approximately 2000 physical pages represent. Many documents undoubtedly do not concern the user at the time of his first modeling and its first calculation; he is however absolutely necessary to consult the documents describing the functionalities implementing this first modeling. This for two reasons:*

- *to avoid the errors of use,*
- *but also, to be informed of the possibilities of Code\_Aster close to those which are sought (solutions of skirting) and which could perhaps prove to be useful.*

*It is thus advised to consult the documentation of use according to the step suggested hereafter.*

*Instruction manual*

: 6/12

### 2.1

**Can Code\_Aster cover subject of my problem?**

*Four documents claim to answer this question. They are presented more synthetic to*

*more complete.*

### ***2.1.1 For a fast answer***

***To consult the pages of the plate of presentation of the fields of modeling of the code, on the site Web section Produced, where the phenomena modélisables by the code are described synthetically.***

### ***2.1.2 For a more excavated answer***

***To consult on the document [U1.02.00] Introduction to Code\_Aster, in particular chapters 1.3 (Phenomena, modelings, finite elements and behaviors) and 1.4 (Several methods of analysis) where the phenomena modélisables by the code are described synthetically.***

### ***2.1.3 For a more up to date answer (taking account of the last developments)***

***To consult transparencies of the last presentation of the new functionalities of the code with annual day of the users of Code\_Aster at the date of publication of this document: section Produced Web site.***

### ***2.1.4 For an answer more developed even...***

***One approaches a field of questioning there where the answer cannot be directly brought any more by objects present on the documentary waiter. For example, the answer can be YES and consist in subtleties of modeling or circumvented ways of modeling. It is addressed, in all state of cause, with already informed users. Service AOM (Assistance with the Optimization of Modeling) of the Experience feedback (REX) Aster makes it possible to submit to the Team of Development***

***Aster (EDA) a problem of modeling particular to implement with average the Aster. It type of tender is carried out by emitting a request for expertise by the REX of the interface graph of access to Code\_Aster astk. A person of the EDA is then charged to help it applicant to carry out his modeling.***

## ***2.2***

***Code\_Aster it already dealt with problem comparable (close) with mien?***

***Two ways are proposed: the way of the elementary cases tests, the way of the industrial applications.***

### ***2.2.1 The elementary cases tests***

***In fact elementary cases tests (known as of school, known as also academic) are used to validate the code***

***and to make sure of the conservation of the precision of the results at the time of its weekly update.***

***The user will thus look at if an elementary case test deals with similar problem: Waiter documentary, heading VALIDATION/Case Test By Names, the list of documentations of the names***

*of  
case tests (classified by applicability) is posted like their titles, or, section  
Use/Examples of the site.*

COURTEOUS Mr., Mr. BOIN, J.M. PROIX Key*

*:  
U0.00.01-E Page  
: 7/12*

### *2.2.2 Industrial studies*

*A certain number of studies (applications) industrial were carried out using Code\_Aster and have fact the object of an article in ASTER echoes (last new of Code\_Aster) or of a presentation at the annual day of the users of Code\_Aster.*

*These documented studies are available on the site, Produit section/Applications. One finds there collection of the cards Studies of the periodical ASTER echoes since its creation (10/91, 39 numbers published*

*to the 01/2003) and a collection of industrial studies in all the fields of modeling of the code presented at the time of the annual days of Code\_Aster.*

*One will find also studies industrial in number 60 of Diagram, Simulation in mechanics of structures, 10/1998, accessible since the section Produced.*

*3  
First use of Code\_Aster*

*To consult the document [U1.01.04] describing the graphic interface of access to Code\_Aster ask.*

*The simplest way to carry out a calculation with Code\_Aster is to start from a nearby example which*

*is most of the time in the elementary cases tests described in the Handbook of Validation. The command files associated with the cases tests described in documentation with validation are located in the repertory astest of the version used. On the waiter of centralized calculation of EDF R & D, they are in /aster/vx/STAx/astest where X is the number of the version in exploitation (6 at the date of writing of this document).*

*This way of proceeding by analogy, appreciated generally well by the community of mechanics, should not replace a constructive step completely but, mistrust, them command files associated with the case-tests (or those written by the colleagues) are not always realized in the most skilful way. Indeed:*

- these files were written at various times of the evolution of the code and do not profit thus not necessarily of the recent contributions allowing to simplify or supplement the study,*
- of many possibilities is generally offered to complete same work which are adapted more or less well to each case.*

*It is thus necessary, to take the practice to consult this handbook of validation to each new need.*

### **3.1** *Great principles and key stages of a calculation*

*One exposes hereafter a read path taking as a starting point the the great obliged stages of a study mechanics with Code\_Aster. In this step, three documents are proposed with the reading.*

#### **3.1.1** *Great principles of Code\_Aster*

*To consult on the document [U1.03.00] the great principles of Code\_Aster, which presents summarily principles of operation and principal rules of use.*

*Instruction manual  
U0.00 booklet: General  
HT-66/03/002/A*

### **3.1.2 Simple example of use of Code\_Aster**

**To consult on the document [U1.05.00] simple Example of use of Code\_Aster, the orders “impossible to circumvent”, on a calculation of cylindrical reserve mean in hydrostatic pressure, modeling axisymmetric.**

## **3.2 grid**

**The structure of the file of Aster grid is described in the document [U3.01.00] Description of file of grid of Code\_Aster.**

**If the initial grid results from an external maillor with Aster such as for example GMSH, GIBI or I DEAS, interfaces and Aster orders which create starting from the objects produced by these pre processors of the objects of the grid of Aster (which are not a copy of the initial objects; their significance can change, of new objects can be created) are described in the documents:**

**[U3.02.01] Interface of the file of grid GMSH with Aster,  
[U3.03.01] Interface of the file of grid I-DEAS with Aster,  
[U3.04.01] Interface of the file of grid GIBI with Aster,  
[U7.01.01] Procedure PRE\_IDEAS,  
[U7.01.11] Procedure PRE\_GIBI,  
[U7.01.31] Procedure PRE\_GMSH,**

**See also [U7.01.21] Reading of a grid to format MED (Model of Data exchange).**

## **3.3 orders**

**The description of the orders of Code\_Aster are contained in the parts U4 and U7 of the Handbook of Use. It is undoubtedly with these 2 parts of handbook that the Aster user will generally have resort. They are organized in the U4 handbook according to a scenario which follows them logically great stages of a calculation:**

**U4.1-  
Allowance of the resources disc and memory,**

**U4.2-, U7.01. - in U7.03. -**

*Acquisition of the data of grid,*

**U4.3- and U4.4-**

*Modeling (assignment of the finite elements, materials, loadings, etc...),*

**U4.5-**

*Resolution of the system of equations (calculation)*

**U4.6-, U4.7-, U4.8-, U7.03 with U7.05. - Post treatment and examination of the results**

*Finally the document [U4.01.00] **How to read the documentation of the orders**, explains in particular significance of the métacaractères and the typography which one meets in documentation of the syntax of the orders.*

*Instruction manual*

*13/06/03*

*Author (S):*

**COURTEOUS Mr., Mr. BOIN, J.M. PROIX Key**

*:*

*U0.00.01-E Page*

*: 9/12*

**3.4**

**Notes of use**

*A certain number of modelings or type of modelings (such as for example under static structuring, the mechanical cushioning, the thin hulls, etc) are the subject of notes of use. The related documents will be available on the waiter in the U2 part of the Handbook of use.*

**3.5**

**Finite elements, modelings of the phenomena**

*From the numerical point of view, the choice of the finite elements for a type of modeling is responsibility for the user. The mathematical description of the modelings supported by finite elements is in the **Handbook of Reference**. The description of the degrees of freedom of these elements like their possibilities of modeling (supported loadings, fields produced, non-linear possibilities, etc...) are in the documents:*

***U3.1-: Mechanical modelings,  
U3.2-: Thermal modelings,  
U3.3-: Acoustic modelings.***

### **3.6**

#### ***Structures of user data of the result type***

*The operators (orders) of Aster calculation create objects of which the structuring of the data that they must be absolutely known users contain. **Part 5 of the Instruction manual** their is entirely devoted.*

*It is advisable to start by reading the two general documents which describe the **generic structure** data of the result type and **accessible fields of sizes**:*

- [U5.01.00] Structure of data result,*
- [U5.01.01] accessible Fields in the Structures of data result,*

*Then, it is advisable to consult the documents which describe the specific organization of the structure data produced by the operator. For example, results of a modal calculation produced by operator `MODE_ITER_SIMULT` have a structure of data which can be of `mode_meca` type described in the document [U5.01.23] **Structure of data mode\_meca and mode\_meca\_c**.*

*Finally and especially, it is imperative of very carefully reading the documents devoted to the orders Aster dedicated to the impression of the results (on listing or files).*

*Initially two generic documents:*

***[U4.91.01] Procedure IMPR\_RESU (FORMAT = “RESULT” and “ASTER”)***

***[U4.33.01] Procedure IMPR\_COURBE.***

*Then five documents of description of the orders which generate files of results to the format `MED`, `GMSH` and `ENSIGHT` and with the formats accepted by the post processors `I-DEAS` and `CASTEM` (Gibi):*

***[U7.05.01] Procedure IMPR\_RESU (FORMAT=' IDEAS'),***

***[U7.05.11] Procedure IMPR\_RESU (FORMAT=' CASTEM'),***

***[U7.05.21] Procedure IMPR\_RESU (FORMAT=' MED'),***

***[U7.05.31] Procedure IMPR\_RESU (FORMAT=' ENSIGHT'),***

***[U7.05.32] Procedure IMPR\_RESU (FORMAT=' GMSH'),***

*Instruction manual*  
*U0.00 booklet: General*

## 3.7

### ***Errors in the command file***

*The constitution of a command file Aster is a stage obliged for the user. Currently, the user has the choice between constituting this file with the hand or building it using the interface graph EFICAS “Editor of rather natural use, Command file Aster...”.*

*Moreover, it gives access directly to electronic documentation.*

*If the command file is built with the hand and if Aster detects a syntactic error, grammatical even semantic in this file, of the brief replies to cure the errors met are in [U1.03.01] Supervisory and process control language.*

## 3.8 Assistance telephone

*The Technical aid Telephone Aster for the use is ensured by an external speaker, whose co-ordinates are reproduced on the Web site, heading Services (necessary access Intranet).*

## 4

### ***Questions and answers about the documentation of Code\_Aster***

#### 4.1

### ***I have it the most up to date version of the document?***

*If the document is consulted electronically on the waiter the answer is **YES**. If the document is resulting from a handbook of pocket paper then, on the waiter, to check if this document were not the object one*

*update in its electronic version. It is necessary to take the practice to think that the handbook paper is a photograph at a given moment of electronic documentation (the date of edition of these handbooks appear very obviously on first page).*

*This question occurs at the time of errors met during the execution. It is then necessary to be turned towards the **Monitoring sheet Quality** of the version of the code which one uses (section *Produit/Qualité* of part *Intranet* of the site).*

### ***4.2 Which is the documentation (the whole of the documents) which applies to the current version of exploitation of the code?***

*They are the documents contained in the waiter even if those *Ci* carry a n° of version of code lower than the current version and carry old dates. For each Handbook, the list of these documents (documents valid for the current version) appears in under **Synopsis** heading.*

### ***4.3***

#### ***I have it right to contact the author of the document directly? ...***

*... because I do not include/understand something or that I discovered an error there?*

*It is advised to initially pass by the Telephone Assistance Aster (cf [§3.8]) which will answer majority of the questions.*

*In the event of complex request, it is possible to contact the author of a document by taking care of to trace this intervention by emitting a card of the type AOM (cf [§2.1.4]) in the Experience feedback.*

#### ***4.4 Then I to contribute to a better quality of documentation Aster?***

***YES, (it is even recommended), errors and suggestions are to be announced by the writing of a Card of Evolution of Documentation in the Experience feedback of the graphic interface of access to Code\_Aster.***

#### **4.5**

***I prefer a documentation paper all the same***

*In ordering from code-aster@edf.fr*

#### ***4.6 I want to perfect my knowledge in the possibilities and the use of Aster***

*The technical documentation of Code\_Aster (more generally all documentary objects Aster present on the documentary waiter) are not the only tools which answer this concern. In addition to the documents of which it was question at the time of the presentation of the read path documentation of use, one will approach the following events:*

- Courses trainings: initiation with Aster, basic training with the use, thermo plasticity, with postprocessings,*
- Aster echoes, quarterly, the last news of Code\_Aster,*
- Quarterly ordinary Séance of the Club of the Users Aster,*
- Grande annual Day of the Users Aster, generally at the beginning of March.*

**Note:**

*The training courses organized by EDF R & D are intended to users EDF and their partners. Users of Free Code\_Aster, consult the Services section for to know the list of the distributors.*

## ***Introduction to Code\_Aster***

### **Warning:**

***One proposes to describe here, the philosophy and the applicability of Code\_Aster, without developing in detail methodologies of study usable.***

***This document is a first making of contact with Code\_Aster and was thus written with a concern of concision. It does not have the role to index all modelings or possible types of analysis with Code\_Aster, and is not substituted to in no case with the plate of the Version 7 which draws up a panorama of it exhaustive.***

***All the information, provided here or in the various handbooks, is given to describe, with maximum of precision, contents of Code\_Aster. They do not have as an ambition to deliver a formation with numerical modeling of the behavior of the mechanical structures. Code\_Aster is only the establishment of methods described and shown in various works to which the reader will have to refer, in complement reference material, if necessary. The handbooks of Code\_Aster suppose acquired in addition a formation with the mechanics of the solids and the finite element method.***

## ***The study of the mechanical behavior of the structures***

### **1.1**

#### ***A code general***

*Code\_Aster is a code general for the study of the mechanical behavior of the structures.*

*The priority applicability is that of the mechanics of the deformable solids: that justifies it a number of functionalities attached to the mechanical phenomenon. However, the study of the behavior mechanics of the industrial components requires beforehand the modeling of the requests which they are subjected, or of the physical phenomena which modify the parameters of it behavior (fluid intern or external, temperature, metallurgical phase shift, efforts of electromagnetic origin...). For these reasons, Code\_Aster offers several possibilities of “chaining” of the mechanical phenomenon with the phenomena thermics or accoustics, or with external software, as well as a “kit” of construction of problems thermo-hydro-mechanics coupled.*

*Although Code\_Aster can be used for many problems of structural analysis (code*

general), it was developed in particular to allow the study of the components of materials or of machines used in the field of the electricity production and transmission. Thus the priority was data with the modeling of the isotropic metal structures, géomatériaux and the components of composite material or reinforced concrete structure.

The nonlinear analyses, as well in mechanics in thermics, are in the middle of Code\_Aster: their effective treatment required the development of powerful and relatively simple algorithms of use, even if the goal is not to make them function in “block box”. For the studies complexes, it is thus necessary to include/understand the nature of the operations carried out by the code, so of being able to control them in an optimal way: one refers then to the theoretical notes giving the details the modelings and methods, gathered in the Handbook of Reference.

The setting under Quality assurance to be able to carry out industrial studies justifies several choice:

- existence of a version of fixed and documented reference code,
- provision of complete, fixed but parameterized algorithms,
- principle of orthogonality of the orders (independence of the context of use),
- objective of complétude of modelings usable.

## 1.2

### **Method for calculation with Code\_Aster**

A structural analysis carried out with Code\_Aster consists of the sequence of a certain number of orders described within a “command file” in format text. The engine and the interpreter this command file is the language script PYTHON. It is thus possible to use all them functionalities brought by PYTHON. See in particular the docs [U1.03.01], [U1.03.02] and them examples of use [U1.05.00] and [U1.05.01]. Each order (for example reading of the grid, affection of the data material, linear static calculation) produced a “concept result”, together of structures of data which the user can handle and re-use in the further orders of calculation (for example grid, the field of data material, the field of displacements...).

The syntax of all the orders is described and commented on in the handbooks U4 and U7 of documentation of Use.

In order to simplify the task of the user, there are total orders which gather the sequence ad' hoc of operations for a certain number of calculation case (for example static linear - order MECA\_STATIQUE, nonlinear statics - order STAT\_NON\_LINE, thermics

*nonlinear - order THER\_NON\_LINE, etc). Some were developed directly of integrated manner, others are macros-orders in Python which do nothing but manage the calls with the various unit orders (as MACRO\_MATR\_ASSE which makes it possible to calculate and to assemble the matrices of mass, damping and rigidity of a structure).*

*There are also macro-orders especially dedicated to certain applications (see [§4]).*

: 4/14

*At the end of a calculation, it is often possible to enrich the data-processing object containing the “concept result” obtained, by carrying out other calculations a posteriori: for example, starting from the field of displacements and of the constraints at the points of Gauss obtained in a mechanical calculation, one can*

*to calculate the field of deformations, the stress field interpolated to the nodes, etc One then invites that to implement a “option” of calculation, which is affublée of a barbarian name, but which follows one*

*logic “quoi\_où\_comment” (for example option EPSI\_NOEU\_DEPL for the deformations data with the nodes starting from the values of displacements).*

## **1.3**

***Phenomena, modelings, finite elements and behaviors***

### ***1.3.1 Concepts***

***One calls “phenomenon” a family of physical problems resting on the same type unknown factors (and associated a type of conservation equation): for example, the phenomenon mechanics calls upon the unknown factors of displacement, the thermal phenomenon with the***

*unknown factors of temperature. According to modeling used, the number of unknown factors of this type can vary (for example one needs in each node only for one unknown factor for temperature in 3D, but 3 unknown factors are used for the hulls).*

*Note:*

*For the coupled problems of thermo-hydro-mechanics, this concept was extended in measure where one gathers, in this case, under the “mechanical” phenomenon, the whole of conservation equations associated with the problem thermo-hydro-mechanics.*

*One calls modeling the manner according to which continuous equations governing a phenomenon given are discretized, with the assistance of possible complementary assumptions (plane deformations, model of beam, models hull...). In mechanics, for example, one can find modelings 3D, 2D plane deformations, 2D forced plane, hulls 3D, plates, beams of Euler, beams of Timoshenko, pipes, etc... Each modeling uses a set of degrees of freedom which is to him clean: for example displacements in the 3 directions of space for modelings of continuous medium 3D, 3 displacements and 3 rotations for hulls 3D, etc*

*The couple phenomenon/modeling makes it possible to affect in a bijective way a type of finite element to each type of mesh of the grid.*

*In Code\_Aster, one calls “finite element”, for a given modeling, the triplet consisted:*

*.  
the nature of the mesh support (representing a piece of volume or border: hexahedron, tetrahedron, triangle, quadrangle, segment...): it is topological information (it includes it a number of nodes);*

*.  
laws of interpolation of the unknown factors (functions of form);*

*.  
“options” of calculation which the element “can” calculate (the operations for which calculation of the adequate integrals was programmed: for example, elementary term of rigidity, elementary term of surface force, elementary term of mass...).*

*A characteristic of Code\_Aster is to affect the boundary conditions and the loadings of edges to specific elements of edge, and not with the borders of the finite elements of volume.*

*The behavior is at the base a physical notion related to the properties of material. It is expressed then in a mathematical way. For example, in mechanics, one calls relation of behavior the relation which binds the stress field to the field of deformations, is in a direct way*

*(elastic behavior), that is to say in an incremental way (incremental behavior). During one calculation, the relation of behavior is expressed in each point of Gauss. In thermics, one used the term "behavior" to qualify the physical field associated with the resolution of the equation model of conduction-diffusion: two great classes of behaviors, which comprise each one several subcategories, are it thermal (possibly coupled with the hydration) and it drying.*

### *1.3.2 The mechanical phenomenon*

*The mechanical phenomenon is modelled to achieve two principal goals:*

*.*

*determination of the internal state, in particular of the state of stress in any point of one structure, under various requests representing the conditions of operating.*

*knowledge of this state of stress makes it possible to continue the analysis of the behavior mechanics from the point of view:*

*- rules of construction particular to each type of structure, in particular them*

*Rules of Design or Construction (RCC...);*

*- harmfulness of defects and their possible propagation: defects inherent in*

*development process of the component or the structure (inclusions, imperfections*

*geometrical...) or resulting from the conditions of operating (cracking, erosion...);*

*-*

*study of the behavior in cyclic loading and analysis with tiredness;*

*-*

*prediction of the working loads with evolution of the internal state.*

.

*determination of the deformed configuration induced by a permanent loading (static) or resulting from a slow evolution (quasi-static) or more rapid (dynamic) of loadings or of the boundary conditions. The knowledge of this deformed configuration, and possibly speeds and of corresponding accelerations, allows to continue analysis of the mechanical behavior from the point of view:*

-

*vibratory and acoustic behavior;*

-

*transmission of the requests to other structures or components;*

*- risks of impact with the close structures to determine the anomalies of operation or the parameters of wear which can result from it.*

*The levels of modeling which intervene for the study of this phenomenon are:*

.

*the representation of the structure starting from the geometrical form, with several modes of representation possible being able to coexist:*

*- continuous medium corresponding to a three-dimensional, or two-dimensional geometry with various assumptions (forced plane, plane deformations, axisymetry complete or adapted to the decomposition of the loadings in modes of FOURIER),*  
*- structural elements corresponding to a medium with average layer, a medium with fibre average or a discretized medium.*

.

*the representation of the behavior of materials, possibly different, in any point of a structure, with relations of behavior allowing to represent different conditions of use. Many relations of behavior are available (cf plate): linear and nonlinear elasticity, nonlinear hyperelasticity, viscoelasticity, elastoplasticity, élasto-visco-plasticity, damage. Coefficients of the relations of behavior can in general depend on variables known as “of piloting” such as temperature, the metallurgical state, the degree of hydration or drying of the concrete, fluence, etc*

.

*the representation of the boundary conditions and the loadings, for which one has functionalities allowing to represent in any point of the structure, total reference mark or in reference mark defined by the user:*

*- conditions of DIRICHLET: imposed displacement or linear relations enters components of displacement,*

-

*conditions of NEUMANN: force imposed specific or surface loadings and linear, in particular allowing to represent the loadings of pressure,*

-

*voluminal loadings, in particular allowing to represent gravity and them centrifugal loads of the bodies in rotation.*

*These boundary conditions and loadings can depend on time (or of the frequency) and of one or more variables of space.*

*Nonthe linearities taken into account in the mechanical phenomenon are nonthe linearities of behavior, and nonlinearities geometrical (great displacements and great rotations, large deformations, contact and friction, buckling).*

### **1.3.3 Associated phenomena**

***To supplement the representation of the environment of exploitation of the mechanical components, it choice was made include in Code\_Aster of the functionalities allowing the modeling of phenomena frequently associated the mechanical phenomenon.***

#### **1.3.3.1 Phenomenon**

##### ***thermics***

*It makes it possible to determine the thermal response of solid media in steady operation (problem stationary) or transient (evolutionary problem). One models solid conduction, the convectif exchange, the heat transfer between walls, and the radiation ad infinitum. The thermal phenomenon can include modeling with the heating or the cooling of the metallurgical phase shift of steels, what makes it possible to simulate the operations of heat treatment or welding (the identification of behavior is based on experimental diagrams TRC).*

*By analogy solved equations, the thermal phenomenon can also be used for to model the hydration (the unknown factor is the degree of hydration) or the drying of the concrete (the unknown factor is water concentration).*

### **Acoustic 1.3.3.2 Phenomenon**

*The acoustic phenomenon is modelled to achieve two principal goals:*

*.  
the study of the acoustic propagation in closed medium corresponding to the equation of HELMHOLTZ*

*in a compressible fluid, for fields of propagation to complex topology.*

*knowledge of the field of pressure makes it possible to continue the acoustic analysis for to determine:*

*-  
the field of noise levels (expressed in dB),*

*-  
fields of active and reactive acoustic intensity.*

*.  
the study of the vibroacoustic coupled problems 3D corresponding to the behavior vibratory of a structure in a limited field of compressible, nonviscous fluid.*

### **1.3.4 “Couplings” of phenomena**

*So that there is no ambiguity, one will distinguish:*

*.  
the chaining of two phenomena: preliminary study of the first phenomenon which one uses them results like data of the second,*

*.  
coupling of two phenomena: simultaneous resolution of the two phenomena with actually coupled equations (cf [§ 1.3.4.2]).*

#### **1.3.4.1 the chainings intern in Code\_Aster**

*The chaining can be carried out inside Code\_Aster or between this one and an external software (cf [§5.2]).*

*The chainings currently carried out within Code\_Aster are as follows:*

*.  
thermics - mechanics: all the mechanical characteristics of materials can to depend on the temperature and the algorithms available for the mechanical phenomenon allow to exploit the results of a preliminary thermal calculation*

*(deformations*

*anelastic*

*: thermal dilations, shrinking of the concrete...) carried out on a grid*

*possibly different,*

.

*thermics - metallurgy: after a thermal calculation, it consists in calculating the proportions of various metallurgical phases of steels,*

.

*thermics - metallurgy - mechanics: taking into account of four mechanical effects of metallurgical transformations (deformation of phase shift, modification of mechanical characteristics, plasticity of transformation, restoration of work hardening of origin metallurgical),*

.

*electric - mechanics: integrated into the mechanical phenomenon, the electric coupling is limited to the taking into account of the forces of LAPLACE induced by currents of short-circuit in electric cables,*

.

*fluid-mechanics: assignment of field of pressure on a wall deduced from a calculation from mechanics of the fluids.*

*: 7/14*

*1.3.4.2 truths couplings*

*Porous environments*

***The or not saturated porous environments (géomatériaux, grounds, concrete) must be studied in***

***coupling the three equations of mechanics, thermics and hydraulics. The user chooses the behaviors which it wishes to use among a kit of models thermo-hydro-mechanics known as “THM”. It can thus choose to take into account or not the effect of the temperature, and to represent one or two pressures. The choice of each behavior associated with the phenomena selected is carried out within this framework also.***

### ***Interaction fluid-structure***

***Three types of couplings are available in the field of the interaction fluid-structure:***

***·  
the calculation of clean modes of a structure containing (or bathing in) a fluid at rest (with or without free face),***

***·  
the calculation of the vibrations of a structure in a flow and the estimate of the damage while resulting by vibratory tiredness or wear,***

***·  
the taking into account of a boundary condition of infinite fluid the field type.***

## ***1.4***

### ***Several methods of analysis***

#### ***1.4.1 Quasi-static/Transitory statics/***

***To implement various modelings, one has several methods of analysis which correspond to various processes of application of the requests.***

***Analyze static: it corresponds to permanent requests for the treatment of thermics stationary and the thermomechanical one. For the linear analyses, the results obtained can be compounds linearly, according to the needs, and are usable to describe the initial state of a process evolutionary.***

***Quasi-static analysis: for all the mechanical processes where one can neglect the phenomena of inertia, implicit incrémentaux algorithms are available to solve the equations of behavior nonlinear with taking into account of loadings and boundary conditions evolutionary.***

***Analyze transitory: in linear and nonlinear thermics, with possible taking into account of the effects metallurgical for metals and of the hydration and drying for the concretes, like for problems of thermo-hydro-mechanics by neglecting the effects of inertia on the mechanical part.***

#### ***1.4.2 Dynamics: physical or basic concept basic modal***

***For the processes where the effects of inertia and propagation must be taken into account***

*(vibratory mechanics, accoustics), one speaks about dynamic analysis.*

*The analysis in physical base is the resolution of the equations in the traditional base of the degrees of freedom physics.*

*The analysis in modal base rests on the preliminary calculation of the values and clean vectors of structure, and consists in projecting the equations to be solved on a basis of clean vectors: the number degrees of freedom of the system to be solved is proportional to the size of the modal base used. It is necessary that the selected modal base is of sufficient size to reproduce the principal ones physical phenomena: modal basic quality standards exist and can be checked (cf [§3.4.3]).*

*For these two types of analyses in physical or modal base, the calculation of answer can be carried out into temporal or harmonic (in the linear case).*

*For the seismic analysis, one can also formulate the problem moving imposed in one relative reference frame (without the movement of drive).*

*Instruction manual*

*Author (S):*

*Mr. ABBAS, F. WAECKEL Key*

*:*

*U1.02.00-C Page*

*: 8/14*

*The linear dynamic analyses can be made by including the effects, of the second order on rigidity, of the initial static stresses calculated as a preliminary (geometrical rigidity, stiffening centrifugal).*

*For the nonlinear problems, two methods of analysis are available:*

•  
*analysis by modal recombination with boundary conditions nonlinear localised for problems with shock,*

•  
*nonlinear dynamic analysis in physical base.*

### *1.4.3 Decomposition in modes of Fourier*

*The analysis in mode of Fourier is intended to calculate the linear response of a structure for geometry axisymmetric subjected to nonaxisymmetric loadings by netting only one section of structure.*

*Concretely, the loading being broken up into Fourier series, the resolution is made for each mode of Fourier then the total answer is obtained by recombination of the results on each mode.*

### *1.4.4 Under-structuring*

*Under structuring consists in gathering several finite elements within a macronutrient and with “to condense” the whole of their rigidity on the degrees of freedom (fewer) of it macronutrient.*

*The resolution of the total problem is limited then to the determination of the unknown factors carried by macronutrients then with the calculation of the unknown factors carried by each “small” element in manner independent within each macronutrient.*

*The advantages of this method are the savings of time and memory, when the complete structure is made of reproduced elements several times by translation or rotation.*

*In dynamics: the modal analysis and calculation of the harmonic or transitory answer can be carried out in traditional dynamic under-structuring by the methods of Craig-Bampton, Mac Neal or for the method known as of the modes of interface.*

*For the structures having a cyclic repetitivity, the methods available allow to calculate the clean modes of the total structure starting from the dynamic behavior of a sector basic.*

## ***A method of resolution: finite elements***

*For the resolution of the various mentioned problems, the only method of established discretization currently is the finite element method.*

2.1

### ***A parameterized establishment of the finite element method***

*A particular effort was made to parameterize the establishment of the finite element method. options of calculation necessary to each method of analysis (static, quasi-static, dynamic) and for each phenomenon (mechanical, thermal, acoustic) are treated overall for all structure, whatever the modelings retained for a particular study.*

*Among the possibilities offered by this architecture, let us quote:*

.

*independence enters the topology of discretization (“grid*

*”) and properties*

*of interpolation of the finite elements assigned to these meshes (“model”) from where the diversity of modelings usable on the same grid,*

.

*the diversity of the relations of behavior and the properties of materials usable in the same model,*

.

*treatment of the boundary conditions and the loadings by specific finite elements of edge, to allow their localization without ambiguity, in particular for the mediums*

*continuous,*

.

*a systematic procedure allowing to treat the dependence of the material properties and of the boundary conditions with various parameters (temperature, time, variable of space...),*

.

*structures of data allowing to use all modelings with the different ones algorithms of resolution.*

*Concerning the treatment of the boundary conditions, let us announce that the method currently privileged is that of the dualisation. It makes it possible to represent any system of linear relations between discretized unknown factors, in particular for the connection of different modelings or the catch in consideration of additional local assumptions (flatness of a face of continuous medium...). One another method by elimination of the imposed degrees of freedom, exists in complement for calculations linear.*

*Concerning the methods of classification of the unknown factors, of storage of the assembled matrices and resolution of the linear systems on which the various algorithms rest, one has today of two direct methods, and an iterative method:*

.

*multi-frontal method,*

.

*factorization LDLT,*

.

*packaged combined gradient (iterative method).*

*One can add solver FETI for decomposition of fields of which a first version (limited to linear and with certain types of boundary conditions) is present in version 7.4.*

*These methods are associated algorithms of renumerotation of the degrees of freedom allowing to optimize the size memory necessary to store the matrices.*

## **2.2**

### ***A wide library of finite elements***

*The library of finite elements is parameterized to allow the assignment, with the various meshes recognized, of the discretized formulations of the phenomena available.*

#### ***2.2.1 Continuous mediums***

***One calls continuous medium a portion of three-dimensional or two-dimensional structure, treated like a volume.***

*Modelings 3D are the simplest forms of continuous medium, because they do not call upon no additional assumption. In modelings 2D, one removes an equation, but one must add assumptions: for example of plane strains or plane stresses in mechanics, of axisymetry in thermics and mechanics.*

*Instruction manual*

*22/07/05*

*Author (S):*

*Mr. ABBAS, F. WAECKEL Key*

*:*

*U1.02.00-C Page*

*: 10/14*

*There are also elements taking of account discontinuities (eg: fissure) by the method level-sets (elements XFEM).*

### *2.2.2 Components of structure*

*The structural elements are built by integrating assumptions on the behavior kinematics three-dimensional (representing more or less well the phenomena of inflection, torsion, shearing, warping...). One can classify them in three categories:*

*elements with average layer (plates, hulls): each type of element rests on assumptions of variation of the unknown factors in the thickness, which makes it possible to calculate the value in any point from that taken on the average layer (and possibly the faces lower and higher in thermics),*

*elements with average fibre (bars, beams, pipes, cables): the assumptions connect for each transverse section the value of the unknown factors in any point with that taken on fibre average,*

*discrete elements (masses, springs, shock absorbers...) : they make it possible to introduce on specific meshes or of the segments of the characteristics expressed in a reference mark Cartesian unspecified.*

### **2.2.3 Connections of modelings**

*The establishment retained for the Finite element method makes it possible to treat structures modelled with various types of machine elements (continuous mediums or structural elements). The connection of finite elements being based on different degrees of freedom, in the same node, can to be made by writing linear relations adapted to the nature of the connection. A methodology particular was developed to transmit as correctly as possible (within the meaning of least squares) torques of effort. One can thus represent the connection satisfactorily between a medium 3D and beams, plates, hulls or pipes, as well as the connections hull-beam, hull-pipe or beam-pipe.*

*The method HARLEQUIN also makes it possible to make connections between grids and/or phenomena different.*

## **2.3**

### **Heterogeneous modelings**

*Techniques of homogenisation make it possible to represent at lower cost a network of tubes bathing in an incompressible fluid, multi-layer composite hulls, or beams multifibre.*

## *Tools of study*

3.1

### *Complements and operations on the grid*

*The concept of grid used by Code\_Aster is tiny room to its simpler expression: list nodes and their co-ordinates, lists meshes and of their topology. With these entities the notion is added of groups of nodes and group of meshes. These groups make it possible to affect different characteristics of modeling (finite elements, materials, boundary conditions, loadings...) and to lead the examination of the results (selective extraction of components). This party taken allows to build a grid, either by manual drafting without useless heavinesses, or by interfacing with mailleurs commercial (Gibi, I-DEAS, GID) or free (GMSH).*

*The user can create groups of nodes or meshes constantly in the unfolding of calculation, thanks to logical or geometrical criteria. One can also modify the structure of data containing the grid: change of reference mark, addition of additional nodes on meshes, creation of new meshes or groups of meshes, destruction of meshes, etc the addition and the ablation of matter can thus be modelled simply.*

3.2

### *Catalogue data material*

*A catalogue of data material under AQ gives access to the values of the parameters of laws of behavior for various materials usually used in the studies. Characteristics materials can be directly included in the command file thanks to an operator specific. For the free version, all the equipment of the catalogue is available but the base is empty (with the load of the user to fill it with his data).*

3.3

### *Treatment and analysis of the results*

#### *3.3.1 Operations on the fields*

*The computed fields can be used in all kinds of algebraic combinations. In analyze linear, one can thus for example deduce the response to a loading complexes answers to the unit loadings on which it break up.*

#### *3.3.2 Statement of values*

*Operations of extraction of the fields of results are available on nodes or meshes. It*

*is also possible to define a way of unspecified observation independent of the initial grid. Various calculations are proposed on the extracted fields (average, standard deviations, invariants tensorial, passage in local axes, etc). For the temporal or frequential evolutions, it is possible to extract the deformation at one moment (a frequency) or the answer from a particular size.*

### **3.3.3 Impression of the results**

*The results can be printed in an easily consultable form or with the format of the tools of visualization (Gibi, I-DEAS, GMSH or ENSIGHT). The user can integrate into the impressions of results of the personalized titles integral of the information extracted the context automatically from the study. Several tools are available to limit the impression to portions of the computed fields.*

*One can also plot curves with various formats (postscript or other formats of images) with assistance of the tracer xmgrace.*

## **3.4**

### **Quality control of the results**

*Many functionalities make it possible to control the quality of the results of a study or of in to facilitate its implementation.*

**: 12/14**

### **Estimators of error and adaptive grid**

*Two categories of estimator of error are available. Coupled with the software of refinement/*

*déraffinement LOBSTER (chaining interns in Code\_Aster via macros-order), they make it possible to adapt the grid in the course of calculation in order to reach a given precision, for one cost optimal calculation.*

### *Checking of the quality of a modal base*

*Criteria of checking of the quality of a modal base make it possible to make sure that the number of clean modes selected makes it possible to correctly represent the phenomena which one wishes to study.*

### *Use of incompatible grids*

*Operators of projection allow to continue on a second grid a calculation carried out on a first grid. One can thus use different grids in thermics and mechanics (including for example a block fissures in the structure only at the time of its analysis in exploitation, after having calculated on a simpler grid the residual stresses due to sound manufacturing process).*

### *Automatic Recutting of the step of time and piloting of the loading*

*In the event of nonconvergence of the total algorithm of resolution, the user can ask so that the code engages of him even a recutting of the steps of time in order to allow convergence. In addition, it is also possible, in order to facilitate the convergence of calculations, to control the application progressive of the loading by the value of a degree of freedom or a deformation.*

### *Indicators of discharge and loss of radiality*

*These indicators make it possible a posteriori to check the validity of the assumptions formulated on nonlinear behavior of a structure, and relevance of the mode of application of the loading retained (not of load).*

**Exchanges with other software**

**5.1**

**Modes of exchanges**

**Code\_Aster can receive in data of the files coming from calculations carried out beforehand by external software. It can also export its results under an exploitable format by others tools. For certain types of analyses (for example interaction ground-structure or ground-fluid-**

*structure with software MISS3D) the two types of chaining can be activated.*

*The exchanges with other software are currently done either with format I-DEAS, or in a format specific to the chained software. Several orders of Code\_Aster allow the reading or the writing objects to be transmitted (fields of results, matrices, loadings...). In certain cases (MISS3D), of the macro-orders facilitate the implementation of a chained calculation. Lastly, it development of format MED creates a standard for the exchange of the files which is brought to to develop.*

## 5.2

### *Software interfaced with Code\_Aster*

*The software of grid interfaced with Code\_Aster is Gibi (subset of CASTEM2000), I-DEAS or GMSH. For the visualization of the results, one can use Gibi, I-DEAS, ENSIGHT or GMSH.*

*The principal computation softwares which can be chained with Version 7 of Code\_Aster are them following:*

- .  
**CIRCUS**  
*: vibrations of the circuits of pipings and lawful calculation,*
- .  
**N3S-SYRTHES**  
*: analyze thermal in the presence of flow,*
- .  
**EOLE**  
*: acoustic propagation in flow,*
- .  
**Dynamic EURO\_PLEXUS**  
*rapid*
- .  
**MISS3D**  
*: propagation of waves in the grounds laminated (seism) by elements of border,*
- .  
**LADY**  
*: analyze vibratory experimental,*
- .  
**LOBSTER**  
*: refinement and déraffinement of grid starting from an estimator of error,*
- .

**MEFISTO**

**: calculation of reliability,**

.

**SATURN**

**: code of mechanics of the fluids.**

### ***1 Principles Generals***

***Version 6 of the Code Aster makes it possible to carry out structural analyses for the phenomena thermics, mechanics, thermomechanical, or thermo-hydro-mechanics coupled, with one or not linear linear behavior, and of calculations of internal accoustics.***

***Nonthe linearities relate to the behaviors of the materials (plasticity, viscoplasticity,***

*damage, effects metallurgical, hydration and drying of the concrete,...), the large ones deformations or great rotations and the contact with friction. One will refer to the plate of presentation of version 6 for the presentation of the various functionalities.*

*The current industrial studies require the placement of tools of grid and visualization graph, which does not form part of the Code. However, several tools are usable for these operations via procedures of interface integrated into the Code.*

*To make a study, the user must, in general, prepare two data files:*

*· the file of grid:*

*to define geometrical and topological description grid without choosing, at this stage the type of formulation of the finite elements used or the physical phenomenon to model. Some studies can result in using several files of grid.*

*This file of grid, in general, is produced by an interface integrated into the Code Aster to leave of a file coming from a software of grid used out of preprocessor (GIBI, GMSH, IDEAS...). Information which this file must contain is specific to Code\_Aster. They define traditional entities of the finite element method:*

*· nodes: points defined by a name and their Cartesian co-ordinates in space 2D or 3D,*

*· meshes: plane or voluminal named topological figures (not, segment, triangle, quadrangle, tetrahedron,...) to which will be able to apply various types of elements stop, boundary conditions or loadings.*

*To improve safety of use and comfort of the operations of modeling and of examination of the results, one can define, in the file of grid, of the levels of entities superiors, having an unspecified property jointly and who could be used directly by their name:*

*· groups of nodes: named lists of names of nodes,  
· groups of meshes: named lists of names of meshes.*

*One will note, as of now, that all handled geometrical entities (nodes, meshes, groups of nodes, groups of meshes) are named by the user and usable with all moment by their name (8 characters to the maximum). The user will be able to use this possibility to identify explicitly certain parts of the studied structure and to thus facilitate it examination of the results. The classification of the entities is never clarified: it is useful only in-house to point on the values of the various associated variables.*

*· the command file: to define the text of order which allows:*

-

*of reading and if required enriching the data of the file by grid (or other sources of external results),*

-

*to affect the data of modeling on the entities of the grid,*

-

*to connect various operations of treatment: specific calculations, postprocessings,*

-

*to publish the results on various files.*

*The text of order refers to the names of geometrical entities defined in the file of grid. It also makes it possible to define new groups constantly.*

*From the data-processing point of view, these two files are ASCII files in free format. One gives some here*

*principal characteristics:*

*Syntax of the file of grid:*

*· length of line limited to 80 characters,*

*· the allowed characters are:*

-

*26 tiny capital letters A-Z and 26 a-z converted automatically in capital letters, except in the texts (provided between quotes),*

-

*ten figures 0-9 and signs of representation of the numbers (+ - . ),*

## ***character***

***\_*** *white underlined usable in key words or names,*

- *a word must always start with a letter,*
- *the white character is always a separator,*
- *the character % indicates the beginning, until the end of the line, of a comment.*
- *The other rules of reading are specified in the booklet [U3.01.00]*

***Syntax of the command file:***

- *syntax related to the language Python, allowing to include instructions of this language*
- *character # indicates the beginning, until the end of the line, of a comment.*
- *The orders must start in column 1, unless they do not belong to a block indenté (buckles, test)*

***The other rules of reading are specified in the booklet [U1.03.01].***

## ***2 Grid***

### ***2.1 General***

***The structure and the syntax of the file of grid are detailed in the Booklet [U3.01.00].***

***This file can be written (for elementary grids) or be modified manually with does not import which text editor. It is a file read in free format, structured in records or under file by imposed key words.***

***Several utilities of conversion are available to allow the file conversion of grid products by other software packages (IDEAS, GIBI, GMSH...) or of the files of grid to format MED.***

### ***2.2***

***The file of grid Aster***

***The file of Aster grid is read first line until the first occurrence of a line begin with the FINE word. This key word is obligatory. The file of grid is structured in independent subfiles starting with a key word and finished by the key word imposed FINSF.***

***This file must comprise at least two subfiles:***

- *co-ordinates of all the nodes of the grid in a Cartesian reference mark 2D (COOR\_2D) or 3D (COOR\_3D).*
- *the description of all meshes (TRIA3, HEXA20, etc...), on which one will affect then physical properties, finite elements, boundary conditions or loadings.*

*It can possibly contain groups of nodes (GROUP\_NO) or meshes (GROUP\_MA) for to facilitate the operations of assignment, but also the examination of the results.*

*Instruction manual*

*Author (S):*

*J.M. PROIX, J.R. LEVESQUE Key*

*:*

*U1.03.00-D Page*

*: 4/16*

*It is essential to explicitly create at this stage the meshes located on the borders of application of the loadings and boundary conditions. One will find then, in the file of grid:*

- meshes of edge of the elements 2D necessary,*
- meshes of face of the elements 3D solid masses necessary;*
- groups of meshes of associated edge and/or face.*

*This constraint becomes bearable when one uses an interface, which does the work from indications provided at the time it grid (see documents PRE\_IDEAS [U7.01.01] or PRE\_GIBI [U7.01.11]).*

*2.3*

*The description of the meshes*

*Conventions of description of the topology of the meshes and conditions of use of different types of meshes are described in the booklet [U3.01.00].*

*The principal types of meshes recognized are identified by the following reserved key words [U3.01]:*

*/*

*POII*

*specific mesh*

*/SEG2/*

*SEG3/SEG4*

*segments with 2, 3, or 4 nodes*

*/TRIA3/TRIA6/TRIA7 triangles to 3, 6 or 7 nodes*

*/QUAD4/QUAD8/QUAD9 quadrangles to 4, 8 or 9 nodes*

*/HEXA8/HEXA20*

*/HEXA27*

*hexahedrons with 8, 20 or 27 nodes*

*/*

*PENTA6*

*/*

*PENTA15*

*pentahedrons with 6 or 15 nodes*

*/*

*TETRA4*

*/*

*TETRA10 tetrahedrons to 4 or 10 nodes*

*/*

*PYRAM5*

*/*

*PYRAM13 pyramids to 5 or 13 nodes*

**2.4**

*interfaces*

*These interfaces make it possible to convert the files, with or without format, used by different computer software package or codes, with the conventional format of the file of grid Aster.*

*The currently available interfaces are those which make it possible to use maillor IDEAS, it maillor GIBI of CASTEM 2000, maillor GMSH, and to treat the files of grid with the format of exchange MED.*

**2.4.1 Universal file IDEAS**

*The interface is made using order PRE\_IDEAS [U7.01.01]*

*The convertible file is the universal file defined by documentation I-DEAS (see Fascicule [U3.03.01]). The recognition of version IDEAS used is automatic.*

*A universal file IDEAS consists of several independent blocks called “dated sets”. Each “set dated” is framed by the character string -1 and is numbered. “Dated recognized sets” by the interface are described in the booklet [U3.03.01].*

#### ***2.4.2 The file of grid GIBI***

*The interface is made using order PRE\_GIBI [U7.01.11].  
The convertible file is the ASCII file restored by the order TO SAVE FORMAT of CASTEM 2000.  
The precise description of the interface is given in [U3.04.01].*

#### ***2.4.3 The file of grid GMSH***

*The interface is made using order PRE\_GMSH [U7.01.31].  
The convertible file is the ASCII file restored by order SAVE of GMSH.*

## **2.4.4 The file of grid to format MED**

The interface is made using order LIRE\_MAILLAGE (FORMAT: "MED") [U4.21.01]).

MED (Modeling and Data exchanges) is a neutral format of data developed by EDF R & D for the data exchanges between computer codes. Files MED are binary files and portables. The reading of a file MED by LIRE\_MAILLAGE, makes it possible to recover a grid product by any other code able to create a file MED on any other machine. This format of data is in particular used for the exchanges of files of grids and results between ASTER and the tool of refinement of grid LOBSTER. The precise description of the interface is given in [U7.01.21].

## **2.5**

### **The use of incompatible grids**

Although the finite element method recommends the use of regular grids, without discontinuity, to obtain a correct convergence towards the solution of the continuous problem, it can be necessary for certain modelings to use incompatible grids: on both sides of a border, the grids do not correspond. The connection of these two grids is then managed on the level of the command file by key word LIAISON\_MAIL of the order AFFE\_CHAR\_MECA. This makes it possible in particular to finely connect a zone with a grid with another zone where one can be satisfied with a coarse grid.

## **2.6**

### **Adaptive grid**

Starting from an initial grid, it is possible to adapt the grid, to minimize the made error, with assistance of the macro order MACR\_ADAP\_MAIL, which calls upon the software LOBSTER.

Software of  
adaptive grid LOBSTER functions on grids made of segments, triangles, tetrahedrons.

This adaptation of grid is placed after the first calculation with *Code\_Aster*. An indicator of the error will have been calculated. According to its value nets by mesh, the software LOBSTER will modify it

grid. It is also possible to interpolate fields of temperature or displacement with nodes of the old grid towards the new one [U7.03.01].

### 3 Orders

#### 3.1

##### The command file

The command file contains a whole of orders, expressed in a specific language in *Code\_Aster*. In complement of the characteristics of file described in paragraph 1, one will find the detailed syntax of the language in the booklet [U6.02.00]. These orders are analyzed and carried out by a software layer of *Code\_Aster* called “supervisor”.

#### 3.2

##### The role of the supervisor

The supervisor carries out various tasks, in particular:

- a phase of checking and interpretation of the command file,
- a production run of the interpreted orders.

These tasks are detailed in the booklet [U1.03.01].

The command file is treated starting from the line where the first call to the procedure is **BEGINNING ()** or with the procedure **CONTINUATION ()**, and until the first occurrence of the order

**END ()**. The orders located before **BEGINNING ()** or **CONTINUATION ()** and after **END ()** are not

carried out, but must be syntactically correct).

## ***Great principles of operation of Code\_Aster***

***Date:***

***26/06/03***

***Author (S):***

***J.M. PROIX, J.R. LEVESQUE Key***

***:***

***U1.03.00-D Page***

***: 6/16***

**· Syntactic Phase of checking:**

**-**

**reading and syntactic checking of each order; any error of detected syntax makes the object of a message, but the analysis continues,**

**- checking that all the concepts used as arguments were declared in one order preceding like produced concept of an operator; it is also checked that the type this concept corresponds to the type required for this argument.**

**· Production run:**

**-**

**the supervisor activates successively the various operators and procedures, which carry them out tasks envisaged.**

### **3.3**

#### **Principles and the syntax of the process control language**

**The modular concept of *Aster* makes it possible to present the Code like a succession of orders independent:**

- the procedures, which do not produce results directly, but ensure, amongst other things, management of the exchanges with the external files,**
- the operators, who carry out an operation of calculation or data management and produce one concept result to which the user gives a name.**

**These concepts represent structures of data, that the user can handle. These concepts are typified at the time of their creation and could be used only as argument of entry of corresponding type.**

**The procedures and the operators thus exchange information necessary and of the values by the intermediary of the named concepts**

**The complete syntax of the orders and its implications on the drafting of the command file**

are detailed in the booklet [U1.03.01]. Here an example of some orders is given (extracted the example with accompanying notes in [U1.05.00]):

```
email = LIRE_MAILLAGE ()

mod1 = AFFE_MODELE (GRID = email,
AFFE=_F (TOUT=' OUI',
PHENOMENE=' MECANIQUE',
MODELISATION=' AXIS'))

f_y = DEFI_FONCTION (NOM_PARA = "Y"
VALE =_F (0. , 20000. ,
4., 0. )
)

charg = AFFE_CHAR_MECA_F (MODEL = mod1
PRES_REP =_F (GROUP_MA = ("lfa", "ldf"),
CLOSE = f_y))

.....
res1 = MECA_STATIQUE (MODELE=mod1,
.....
EXCIT=_F (LOAD = charg),
....)

res1 = CALC_ELEM (reuse=res1, RESULTAT=res1,
.....
MODELE=mod1,
OPTION= ("SIGM_ELNO_DEPL", "EPSI_ELNO_DEPL"))
```

:

## **U1.03.00-D Page**

**: 7/16**

**Some general points will be noted, which one can observe on the preceding example:**

- **any order starts in first column,**
- **the list of the operands of an order is obligatorily between brackets, as well as the lists elements,**
- **a nom\_de\_concept can appear only once in the text of order like produced concept, on the left of the sign =,**
- **the re-use of an existing concept like produced concept, is not possible that for operators specified to this end. When one uses this possibility (réentrant concept), order uses the reserved key word then “reuse”.**

**This operation is done:**

- **is with crushing of the initial values. As example let us announce factorization in place of a matrix of rigidity:**

**matass = FACT\_LDLT (reuse=matass, MATR\_ASSE= matass)**

- **is with enrichment of the concept.**

### **3.4**

#### **Regulate of overload**

**A rule of overload usable, in particular for all the operations of assignment, was added with the rules of use of a mot\_cle\_factor with several lists of operands:**

- **the assignments are done by superimposing the effects of different mot\_clé,**
- **in the event of conflict, the mot\_clé last overrides the precedents.**

**Example: one wishes to affect various materials MAT1, MAT2 and MAT3 with certain meshes:**

**to subdue = AFFE\_MATERIAU (MAILLAGE= mon\_mail**

**AFFE = \_F (ALL = “YES”, MATER = MAT1),**

**\_F (GROUP\_MA = “mail2”, MATER = MAT2),**

**\_F (GROUP\_MA = “mail1”, MATER = MAT3),**

**\_F (MESH = (“m7”, “m8”), MATER = MAT3))**

- **One starts by assigning material MAT1 to all the meshes.**
- **One assigns then material MAT2 to the group of meshes mail2 which contains, the meshes m8, m9 and m10.**
- **One assigns finally material MAT3 to the group of meshes mail1 (m5, m6 and m7) and to the meshes m7 and m8, which causes conflict since the mesh m7 forms already part of the mail1 group. regulate of overload will then be applied and one will obtain finally the field of following material:**

**MAT1**

**:**  
**meshs m1 m2 m3 m4**

**MAT2**

**:**  
**meshs m9 m10**

**MAT3**

**:**  
**meshs m5 m6 m7 m8**

### **3.5**

#### **Data bases associated with a study**

***Code\_Aster* rests, for the management of all the structures of data associated with different concepts handled, on software package JEVEUX. This one deals with the space management memory asked by the user at the time of the request for execution (parameter Report expressed in Megabytes). This space is frequently insufficient to store central all them structures of data. The software package takes then charges some, the management of the exchanges between the memory power station and of the auxiliary auxiliary storages on files.**

**Each entity is affected, during its creation by the code, with a file of direct access. This one can to be regarded as a data base, since it contains, at the end of the execution the repertory (names and attributes) which makes it possible to exploit all the segments of values that it contains.**

**J.M. PROIX, J.R. LEVESQUE Key**

**:**

**U1.03.00-D Page**

**: 8/16**

**Code\_Aster uses several data bases:**

- **the TOTAL data base, which contains all the concepts produced by the operators, thus that contents of certain catalogues on which the concepts are pressed; the file associated with this the later continuation of a study allows. It must thus be managed by the user.**
- **other data bases, used only by the Supervisor and the operators, with the course of an execution, do not require a particular intervention of the user.**

**To make a study, it is to ask for the sequence of several orders:**

- **of the procedures to exchange files with the external world,**
- **of the operators to create concepts progressively produces course of operation of modeling and calculation.**

**The orders which correspond to this sequence of operations can be carried out of various ways, starting from the single achievable module of Code\_Aster:**

- **in only one sequential execution, without intervention of the user,**
- **by splitting the study in several successive executions, with re-use of the results former; starting from the second execution, the access to the data base is done in continuation; with the occasion of a continuation, one can redemand the last order, if it stopped prematurely (lack of time, incomplete or incorrect data detected in phase of execution,...).**

**Beginning**

**order 1**

**order 1**

**order 2**

**order 2**

- 
- 
- 
- 

**Study**

**order I**

**order I**

**Study**

**End**

**order i+1**

**Continuation**

**order i+1**

- 
- 
- 
- 

**order J**

**order J**

**End**

**order j+1**

**Continuation**

**order j+1**

**The continuation is not possible**

- 
- 

**that within the framework of one**

- 
- 

**even version**

**order N**

**order N**

**End**

**To manage these possibilities, it will be noted that three orders play a paramount part. They are those**

**who correspond to the procedures which activate the supervisor:**

**• BEGINNING ()**

**obligatory for the first execution of a study,**

· **CONTINUATION ()**

**obligatory starting from the second execution of a study,**

· **FINE ()**

**obligatory for all the executions.**

**For a given study, one can subject command files having the following structure:**

**Note:**

· *Order INCLUDE makes it possible to include in a flood of orders the contents of another command file. This allows in particular, to preserve a file of the orders principal readable and to place in annexed files of the numerical data bulky (ex: definition of functions).*

· *The command files can be cut out in several files which will be carried out one after the other, with intermediate safeguard of the data base. For that, it is necessary to define the successive command files, whose suffix will be: .com 1, .com 2,..., .com 9. The executions of these files are connected. The data base of the last execution who finished well is preserved.*

**3.6**

**Contribute to the definition of the values**

**3.6.1 Substitution of values**

**Several orders are available to help the user to define the values used like**

arguments, therefore to parameterize its command file:

- to give a name to one or more values:

**name = DEFINI\_VALEUR (STANDARD = [value]);**

or quite simply:

**name = value**

- Evaluer certain mathematical expressions:

**EVAL (expression)**

For example:

**Eptub = 26.187E-3**

**Rmoy = 203.2E-3**

**Rext = DEFINI\_VALEUR (R8 = EVAL ("'''' Rmoy+ (Eptub/2) ''''))**

**= AFFE\_CARA\_ELEM (MODEL will cara = model**

**BEAM =\_F (GROUP\_MA = all, SECTION: "CIRCLE",**

**CARA = ("R", "EP"), VALE = (Rext, Eptub)))**

These possibilities result in a simple substitution of the values each time the Supervisor meet the name chosen by the user.

### 3.6.2 Functions of one or more parameters

It is also often necessary to use sizes functions of other parameters.

Those can be:

- is defined on an external file read by the order, **LIRE\_FONCTION**.

- is defined in the command file by:

-

**DEFI\_CONSTANTE** produces a concept function with only one constant value,

-

**DEFI\_FONCTION** produces a concept function for a size function of one real parameter,

-

**DEFI\_NAPPE** produces a concept function for a list of functions of same size, each element of the list corresponding to a value of another parameter reality.

The concept produced by these operators is of function type and can only be used as argument of operands which accept this type. The operators who accept one argument of the function type have as a suffix **F** (ex: **AFFE\_CHAR\_MECA\_F**). Functions in this case are defined point by point, with a linear interpolation by defect, therefore

closely connected by pieces.

The functions created are discrete tables of the sizes specified with creation.

At the time of a search for value, one proceeds according to the specified characteristics, by direct research or by interpolation in the table (linear or logarithm). One can to specify, during the creation of the function, the prolongation out of the field of definition table, with various rules, or to prohibit it.

· is defined using their analytical expression by the operator FORMULATES: for example:

$\Omega = 3.566;$

linst = (0. , 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, 0.10, 0.20, 0.40 )

F = FORMULA (REAL = '' (REAL: INST) = COS (OMEGA\*INST) '')

F1=CALC\_FONC\_INTERP (FONCTION=F, VALE\_R= linst, NOM\_RESU=' ACCE',)

*Instruction manual*

*Author (S):*

*J.M. PROIX, J.R. LEVESQUE Key*

*:*

*U1.03.00-D Page*

*: 10/16*

The analytical function  $F(T) = \cos(T)$  is then calculated by CALC\_FONC\_INTERP for the moments of the list linst list of moments T.

**3.7**

**How to write its command file with EFICAS?**

To write a command file of *Code\_Aster*, most immediate consists starting from an example already written by others. In particular, the whole of the tests of *Code\_Aster* often constitutes one good starting base for a new modeling.

But there is better: tool EFICAS makes it possible to write in an interactive and convivial way its file of orders, by proposing for each order the list of the possible key words while checking automatically syntax, and by giving access to the documentation of the Instruction manual (booklets [U4] and [U7]).

## 4 Great stages of a study

The great stages of a study are in the case general:

- the preparation of the work, which finishes after the reading of the grid,
- the modeling during which are definite and affected all the properties of finite elements and of materials, boundary conditions and loadings,
- calculation can then be carried out by the execution of total methods of resolution [U4.5-], which are possibly based on orders of calculation and assembly of matrix and vectors [U4.6-]
- operations of postprocessings complementary to calculation [U4.8-],
- operations of impression of the results [U4.9-]
- operations of exchange of results with other software (graphic visualization by example) [U7.05-]

Another way of using *Code\_Aster* consists in exploiting tools trades, available in Code in the form of MACRO\_COMMANDES: let us quote for example the tools trades:

- ASCOUF (modeling of fissured elbows or elbows with under-thicknesses),
- ASPIC (modeling of or not fissured prickenings),
- GOUJ2ECH (modeling of the behaviour of the threaded assemblies).

### 4.1 To start the study and to acquire the grid

One will not reconsider here the possible fragmentation of the command file, which was presented in a preceding paragraph.

The first achievable order is:

```
BEGINNING  
( )
```

**The argument of this order are useful only for the maintenance actions or in case of very large studies.**

**For the reading of the grid, coming from a software of external grid, one can operate of two ways:**

**· to convert the file of a software package by a separated execution, which allows, if required, to modify it by text processing and to preserve it:**

**BEGINNING**

**()**

**PRE\_IDEAS ()**

**END ()**

*Instruction manual*

*U1.0- booklet: Synoptic*

*HT-66/03/002/A*

---

*Code\_Aster* ®

*Version*

*6.4*

*Titrate:*

*Great principles of operation of Code\_Aster*

*Date:*

*Author (S):*

*J.M. PROIX, J.R. LEVESQUE Key*

*:*

*U1.03.00-D Page*

*: 11/16*

**the normal study will be able to then begin for example by:**

**BEGINNING**

**()**

**my = LIRE\_MAILLAGE**

**()**

**· to convert the file right before reading it:**

**BEGINNING**

**()**

**PRE\_IDEAS**

**()**

**my = LIRE\_MAILLAGE**

**()**

## **4.2**

**To assign data of modeling to the grid**

**To build the modeling of a mechanical problem, thermal or acoustic, it is essential to assign to the topological entities grid:**

- a model of finite element,**
- properties of the materials (law of behavior and parameters of the law),**
- of the geometrical or mechanical characteristics complementary,**
- of the boundary conditions or the loadings.**

**These assignments are obtained by various operators whose name is prefixed by AFFE\_. syntax and the operation of these operators already uses the facilities brought by the rules mentioned previously on the use of the key words factor.**

### **4.2.1 Definition of a field of assignment**

**To carry out an assignment, it is essential to define a field of assignment per reference to names of the topological entities defined in the file grid. Five key words are usable for that, according to the specification of the operator:**

- to refer to all the grid by**

**TOUT= “YES”**

- to assign to meshes by**

**MAILLE= (list of names of meshes)**

- to assign to groups of meshes by**

**GROUP\_MA= (list of names of groups of meshes)**

- to assign to nodes by  
**NOEUD=** (list of names of nodes)
- to assign to groups of nodes by  
**GROUP\_NO=** (list of names of groups of nodes)

#### 4.2.2 To affect the type of finite element

On the meshes of the studied structure, which are at this stage only topological entities, it is essential to affect:

- one or more phenomena studied: “**MECHANICAL**”, “**THERMAL**”, “**ACOUSTIC**”;
- a model of finite element compatible with the topological description of the mesh. This assignment induces an explicit list of degrees of freedom in each node and a law of interpolation in the element.

One uses for that the operator **AFFE\_MODELE** [U4.41.01], who can be called several times on even grid. It uses the rules of overload and remanence.

#### Foot-note:

*For a study with several treated phenomena (“**MECHANICAL**”, “**THERMAL**”), it is essential to build a model for each phenomenon, by as many calls to **AFFE\_MODELE**. On the other hand, for a given calculation (mechanical, thermal,...) one needs one and only one model.*

To know the characteristics of the various finite elements available one will refer to booklets [U2-], and [U3-].

*U1.03.00-D Page*

: 12/16

### 4.2.3 To affect material characteristics

It is necessary to assign to this stage characteristics of material, and the parameters associated, with each finite element of the model (except for the directly definite discrete elements by a matrix of rigidity, of mass and/or damping). In other words, **DEFI\_MATERIAU** is used to define one material and **AFFE\_MATERIAU** are used to define a material field by association of the grid. For one calculation given, one needs one and only one field of material.

One can also use the validated characteristics of the catalogue material using the procedure **INCLUDE\_MATERIAU** [U4.43.02].

A certain number of models of behavior are usable: rubber band, orthotropic rubber band, thermics, accoustics, elastoplastic, elastoviscoplastic, endommagment. Let us note that it is possible to define several material characteristics for the same material: rubber band and thermics, elastoplastic, thermoplastic,...

### 4.2.4 To assign characteristics to the elements

During the use of certain types of elements, for the “MECHANICAL” phenomenon, the definition geometrical deduced from the grid does not allow to describe them completely.

One must assign to the meshes the missing characteristics:

- for the hulls: the constant thickness on each mesh and a reference mark of reference for representation of the state of stress,
- for the beams, bars and pipes: characteristics of the cross section, and possibly orientation of this section around neutral fibre.

These operations are accessible by the operator **AFFE\_CARA\_ELEM** [U4.42.01]), who uses, for to simplify the drafting of the order, the rules of overload and remanence.

Another possibility is offered by this operator: that to introduce, directly in the model, of matrices of rigidity, mass or damping on meshes **POI1** (or nodes) or meshes **SEG2**. These matrices correspond to the types of discrete finite elements with 3 or 6 degrees of freedom by node **DIS\_T** or **DIS\_TR** which must be affected at the time of the call to the operator **AFFE\_MODELE**.

### 4.2.5 To affect the boundary conditions and the loadings

**These operations are, in general, essential. They are carried out by several operators of which its name is prefixed by AFFE\_CHAR or CALC\_CHAR. On the same model, one will be able to carry out several calls to these operators to define, progressively study of the boundary conditions and/or loadings.**

**The operators used differ with the phenomenon:**

**“MECHANICAL”**

**AFFE\_CHAR\_CINE**

**AFFE\_CHAR\_MECA given of real type only**

**AFFE\_CHAR\_MECA\_F**

**data of the function type**

**“THERMAL”**

**AFFE\_CHAR\_THER given of real type only**

**AFFE\_CHAR\_THER\_F**

**data of the function type**

**“ACOUSTIC”**

**AFFE\_CHAR\_ACOU given of real type only**

**Moreover, one can establish the seismic loading to carry out a calculation of response moving relative compared to the supports, using order CALC\_CHAR\_SEISME.**

*Instruction manual*

*U1.0- booklet: Synoptic*

*Author (S):*

*J.M. PROIX, J.R. LEVESQUE Key*

:  
**U1.03.00-D Page**  
**: 13/16**

**The boundary conditions and loadings can be defined according to their nature:**

- with the nodes,
- on meshes of edge (edge or face) or meshes support of finite elements, created in the file grid. On these meshes operator **AFFE\_MODELE** has affected the types of elements stop necessary.

**For the detailed description of the operands of these operators and the rules of orientation of the meshes support (total reference mark, local reference mark or unspecified reference mark) one will refer to the documents [U4.44-01], [U4.44-02], and [U4.44-04].**

**The boundary conditions can be treated in two ways:**

- by “elimination” of the degrees of freedom imposed (for linear mechanical models implementing that boundary conditions kinematics (degrees of freedom blocked) without linear relation. One will define in this case the boundary conditions by the order **AFFE\_CHAR\_CINE**.
- by dualisation [R3.03.01]. This method because of its greater general information allows to treat all the types of boundary conditions (degree of freedom imposed, relations linear between degrees of freedom,...) ; the method used results in adding 2 multipliers of **LAGRANGE** for each ddl imposed or each linear relation.

**Each concept produced by the call to these operators, of type **AFFE\_CHAR**, corresponds to a system boundary conditions and loadings indissociable. In the orders of calculation, one can to incorporate these concepts while providing for the operands **CHARGES** a list of concepts of this type.**

## **4.3**

### **To carry out calculations by total orders**

#### **4.3.1 Analyze**

##### **THERMICS**

**To or not calculate to it (S) field (S) of temperature corresponding to a linear thermal analysis linear:**

- stationary (moment 0),

- **evolutionary** whose moments of calculation are specified by a list of realities defined as a preliminary

The orders to be used are:

- **THER\_LINEAIRE** for a linear analysis [U4.54.01],
- **THER\_NON\_LINE** for a nonlinear analysis [U4.54.02],
- **THER\_NON\_LINE\_MO** for a problem of live loads in steady operation [U4.54.03].

Calculations of the matrices and vectors elementary and assembled necessary to the implementation of methods of resolution are dealt with by these operators.

### 4.3.2 Analyze STATIC

To calculate the mechanical evolution of a structure subjected to a list of loadings:

- **MECA\_STATIQUE** [U4.51.01]: linear behavior, with superposition of the effects of each loading,
- **MACRO\_ELAS\_MULT** [U4.51.02]: linear behavior, by distinguishing the effects of each loading,
- **STAT\_NON\_LINE** [U4.51.03]: quasi-static evolution of a structure subjected to a history of loading in small or great transformations, made of a material of which its behavior is linear or not linear, with taking into possible account of the contact and friction.

If this mechanical calculation corresponds to a study of thermoelasticity, one will refer to one moment thermal calculation already carried out. If the material were defined with characteristics depending on the temperature, those are interpolated for the temperature corresponding to the moment of calculation asked.

For the problems of thermohydrromecanic coupled, it is the operator **STAT\_NON\_LINE** who is used to solve simultaneously the 3 problems thermics, hydraulics and mechanics.

***:***

***U1.03.00-D Page***

***: 14/16***

**Calculations of the matrices and vectors elementary and assembled necessary to the implementation of methods of resolution are dealt with by these operators.**

### **4.3.3 MODAL analysis**

**To calculate the clean modes and eigenvalues of the structure (correspondent to a problem vibratory or with a problem of buckling).**

- MODE\_ITER\_SIMULT [U4.52.03]: calculation of the clean modes by simultaneous iterations; eigenvalues and vector clean are real or complex,**
- MODE\_ITER\_INV [U4.52.04]: calculation of the clean modes by iterations opposite; values clean and vector clean are real or complex,**
- MACRO\_MODE\_MECA [U4.52.02]: reduce the modal analysis while cutting out automatically the interval of frequency in under intervals,**
- MODE\_ITER\_CYCL [U4.52.05]: calculation of the clean modes of a structure with repetitivity cyclic starting from a base of real clean modes.**

**These four operators require as a preliminary the calculation of the assembled matrices [U4.61-].**

### **4.3.4 Analyze DYNAMIC**

**To calculate the dynamic response, linear or not linear, of the structure. Several operators are available. One can quote for example:**

**DYNA\_LINE\_TRAN [U4.53.02]: temporal dynamic response of a linear structure subjected to one transitory excitation,**

**DYNA\_LINE\_HARM [U4.53.02]: dynamic response complexes of a linear structure subjected to one harmonic excitation,**

**DYNA\_TRAN\_MODAL [U4.53.21]: transitory dynamic response in coordinated generalized by modal recombination.**

**These three operators require as a preliminary the calculation of the assembled matrices [U4.61-].**

**DYNA\_NON\_LINE [U4.53.01]: temporal dynamic response of a nonlinear structure subjected to a transitory excitation, which also calculates the assembled matrices.**

## **4.4 results**

**Results produced by the operators realizing of calculations by finite elements [U4.3-], [U4.4-] and [U4.5-] are of two principal types:**

- **is of the type of field (by elements or with the nodes) when it acts operators not producing that only one field (for example RESO\_LDLT),**
- **is of the RESULT type strictly speaking which gathers sets of fields, accessible by a variable allowing to distinguish them (urgent for a result resulting from one evolutionary calculation, frequency for a result coming from an algorithm of search for modes clean or of harmonic answer,...).**

**A field in a concept of the RESULT type is located:**

- **by a variable of access which can be:**
  - **a simple sequence number referring to the order in which the fields were arranged,**
  - **a parameter preset according to the type of the concept RESULT:**
    - **frequency or number of mode for a RESULT of the mode\_meca type,**
    - **moment for a RESULT of the evol\_elas type, temper, dyna\_trans or evol\_noli.**

*U1.03.00-D Page*

: 15/16

· by a reference symbol of field referring to the type of the field: displacement, speed, state of stress, efforts generalized,...

In addition to the variables of access of other parameters can be attached to a type of concept RESULT. The contents of these concepts are completely described in the booklet [U5-].

The various fields are built-in in a concept result:

- is by the operator who created the concept, a total order (MECA\_STATIQUE, STAT\_NON\_LINE,...) or a simple order (MODE\_ITER\_SIMULT, DYNA\_LINE\_TRAN,...),
- is during the execution of an order which makes it possible to add an option of calculation in form of a field by element (CALC\_ELEM) or of a field to nodes (CALC\_NO); one says then explicitly that one enriches the concept:

resul

=

operator

(reuse=resul, RESULT =

resul...);

## 4.5

### To exploit the results

The whole of the preceding orders made it possible to build various concepts which are exploitable, by operators of postprocessing of calculations:

- general operators of postprocessing (see booklet [U4.81]), for example CALC\_ELEM, CALC\_NO, POST\_ELEM, POST\_RELEVE\_T,

- operators of breaking process (see booklet [U4.82]), for example CALC\_G\_THETA,
- operator of metallurgy: CALC\_META,
- static mechanical postprocessing (see booklet [U4.83]), for example POST\_FATIGUE, POST\_RCCM,
- dynamic mechanical postprocessing (see booklet [U4.84]), for example POST\_DYNA\_ALEA, POST\_DYNA\_MODAL\_T.

· operators of extractions:

-

of a field in a concept result RECU\_CHAMP [U4.63.1],

-

of a field in co-ordinates generalized for a dynamic calculation with modal base RECU\_GENE [U4.63.2],

- of a function of evolution of a component starting from a concept result RECU\_FONCTION [U4.63.3],

-

and of restitution of a dynamic response in physical base REST\_BASE\_PHYS,

-

an operator of postprocessing of functions or tablecloths CALC\_FONCTION which allows research of peaks, extremums, combinations linear,... [U4.21.9].

Finally two procedures IMPR\_RESU [U4.91.01] and IMPR\_COURBE [U4.33.01] allow the impression and

possibly the creation of exploitable files by other software packages in particular of visualization graph One will retain in particular graphic visualization by IDEAS, GMSH, or GIBI whatever the tool for grid used at the beginning.

## 5 Print files and error messages

*Aster* writes information relating to calculation in three files whose significance is as follows.

### **File Contained**

#### **ERROR**

Errors met during the execution

#### **MESSAGE**

Information on the course of calculation.

Repetition of the command file, provided and its interpretation by

*Aster*.

Execution time of each order.

Messages “system”

#### **RESULT**

Only expressly written results requested from the request of the user and the error messages

Other files are used for the interfaces with the programs of graphic examination.

One distinguishes various types of error messages. The transmitted messages will be only directed according to their type:

### **Code**

#### **Type of message**

#### **Output files**

F

fatal error message, the execution stops after various ERROR

impressions. The concepts created during the execution are lost. MESSAGE

It is used within the framework of the serious detection of error which cannot RESULT

to allow the normal continuation of an order *Aster*

E

error message, the execution continues a little: this type of message ERROR

allows to analyze a series of errors before the program stop. (by MESSAGE

example, syntactic analysis of the command file by the RESULT

Supervisor).

*The emission of a message of the <E> type is always followed by the emission of a message of the <F> type.*

S

error message, the concepts created during the execution are ERROR

validated by the supervisor, the execution stops with “clean” closing MESSAGE TOTAL base. It is thus reusable in CONTINUATION. This RESULT message makes it possible in particular to be secured against a stop system with run of an iterative process.

With

message of alarm. The number of messages of alarm is limited MESSAGE automatically with 5 identical **successive** messages.

RESULT

**It is recommended to the users who have messages of the type**

**With “to repair” their command file to do them**

**to disappear**

I

message of information of the supervisor

MESSAGE

## ***1 Introduction***

***The role of the supervisor is to ensure the command of the course of operations in progress of execution of a program. The instructions of execution are generally provided by the user. This requires a formalization of the communications between the code and its owner, it is the language of order.***

***The Python language is employed to write the catalogue of orders, the supervisor and the files orders user. For the command files, that makes it possible to discharge the supervisor from the task of syntactic analysis, reserved for Python itself.***

***A command file is a succession of call to functions Python (orders), defined in the catalogue of orders. These functions have arguments of entry: words keys and their contents, and of the arguments of exit: produced concepts. The user who composes sound command file must thus be subjected to the general syntax of Python (parenthèsage, indentation...) and with the rules imposed by the catalogue of orders (the provided arguments are coherent with until the function waits).***

***For a first making of contact with the code, the reader will be able not to approach chapter 2.***

***2***

***Mechanism general of operation of the supervisor***

***2.1 Structure***

***general***

***The basic elements brought into play during an execution of an Aster calculation are:***

***.  
the command file, provided by the user,***

***.  
the catalogue of orders: it is a module python of name cata placed in the package  
Cata,***

***.  
the SUPERVISORY high level object,***

***.  
object JDC created by this last and which is finally carried out.***

***The SUPERVISORY object is a python object which analyzes the options transmitted on the line of order, imports the catalogue of orders, created object JDC starting from the command file and carry out this one.***

***Object JDC (name for Command set) is a python object created by the SUPERVISORY object with to leave the text of the command file and the module catalogues orders. It contains the objects***

**STAGE. Object JDC is representative of the command file user.**

**The STAGE objects are representative of each call to Aster orders in the file of order. Each STAGE object bears the name of the order that it reference, the list of the key words credits and their values, the type and the name of the produced concept.**

**Construction then the execution of object JDC start the following actions:**

.  
**analyze syntactic command file user: it is on this level that syntax python is checked (brackets, commas between key words, indentation...). The detection of one error (Syntax Error Python) causes the stop of the execution of Aster. The first error is fatal: the following errors are not sought,**

.  
**construction of the stages: that consists in creating a STAGE object for each call to one order Aster in the command file. This object is recorded at JDC which manage the list of the stages and related concepts,**

.  
**checking of each STAGE: if the call to an order in the file user is incoherent with the catalogue of orders, a report is posted and the execution is stopped on this level. It is the semantic checking,**

.  
**execution itself of the orders: for each stage taken in the order, call to high level routine FORTRAN (op0nnn.f) corresponding.**

## **2.2**

**Total execution or step by step**

**A command set can be built and carried out according to two modes:**

.  
**the total mode for which all the stages of the command set are initially built then carried out in their order of appearance. This mode is chosen by the key word PAR\_LOT=' OUI' in the ordering of starting BEGINNING,**

.  
**the mode step by step for which each stage is immediately carried out after its construction. This mode is chosen by key word PAR\_LOT=' NON' in the order BEGINNING.**

**If the user does not specify anything in the order starting, the total mode (PAR\_LOT=' OUI') is retained. These two modes present each one their advantages and disadvantages.**

**Instruction manual**

**U1.0- booklet: Introduction to Code\_Aster**

**Author (S):**

**C. Key DURAND**

**:**

**U1.03.01-E Page**

**: 5/14**

*The total procedure guarantees to the user that all its file is semantically correct before starting calculations which could fail or not converging. It would be a pity indeed to stop in fatal error after a long resolution because of a key word forgotten in one order postprocessing.*

*The mode step by step builds a stage only after having carried out the preceding one. It thus does not detect that the semantic errors of the pending order and presents the disadvantage described above. It however allows to exploit a result calculated (in a concept) in the command file for, for example, to place conditional instructions there.*

*Here an example of loop with a criterion of stop on the value of a calculated size, stored in the concept of the type counts: RELV [K]. If for example an obligatory key word misses in the call to POST\_RELEVE\_T, that will be detected only after the complete execution of the first MECA\_STATIQUE.*

*On the other hand, the mode step by step makes here possible the assignment of variable SYX since the concept RELV [K] was completely calculated at the time when the supervisor carries out this line.*

**BEGINNING (PAR\_LOT=' NON')**

**RESU= [None] \*10**

**RELV= [None] \*10**

**for K in arranges (1,10):**

**RESU [K] =MECA\_STATIQUE (...)**

**RELV [K] =POST\_RELEVE\_T (...)**

***SYX=RELX [K] [“VMIS”, 4]***

***yew SYX < criterion:  
station-wagon***

***END ()***

***It should be noted that the choice of a procedure conditions the order in which the analysis will proceed semantics (STAGE by STAGE or overall for all the JDC). But, in both cases, the analysis syntactic python is always made as a preliminary for all the command file.***

***Note:***

***EFICAS can exclusively generate and read again only command sets containing orders ASTER, without other instructions python; this independently of the mode Selected PAR\_LOT.***

***2.3***

***The construction of the stages***

***During the construction of each STAGE object, one checks his semantic coherence with the catalogue order to which it refers. Any detected error is consigned in a report who, in total procedure, is delivered after the analysis of all the command file.***

***Semantic examples of checks:***

- respect of the number of arguments of the key words,***
- respect of the type of argument,***
- membership of an argument to a list of possible values,***
- exactitude of the orthography of a key word or a key word factor,***
- compliance with the rules of exclusion or implication between key words,***
- presence of the obligatory key words.***

***This stage, if the order is an operator and produces a concept, this one is typified. The supervisor check that a of the same concept name was not already defined, or if it is employed again, that the order authorizes.***

***2.4***

***Treatment of the macro-orders***

***An macro-order, considering the user, is an ordinary order. In fact, it does not call directly a high level routine FORTRAN but generates other orders.***

***Two types of macro-orders exist:***

***•  
macros in Python,***

***•  
macros supervisory: they are the orders special (BEGINNING, FORMULA, INCLUDE, INCLUDE\_MATERIAU, CONTINUATION) which require a treatment the level of their construction.***

***As well as the JDC itself, the call to an macro-order produces a father object (of type MACRO-ETAPE) which contains wire objects: the stages which the macro one generates, even others macros.***

***An macro-order of the JDC is first of all treated like the other orders (checking syntactic, construction of the macro stage). Then it “is built” by application of the method Build python on object JDC. After its construction, stages of the orders produced by macro are substituted at the stage of macro itself, for later execution.***

*It is important to note that the phase of construction of the macro-orders proceeds right front their execution, and not at the time the total master key on the command file in mode PAR\_LOT=' OUI'.*

*That has two consequences:*

- EFICAS analyzes the syntax of the macro-order itself, but not that of its subcommands.*
- One can on the other hand exploit, in the programming of the macros, the data previously calculated and repatriated in the space of names python, without having to impose it mode PAR\_LOT=' NON' with the user the macro one.*

## **2.5**

### **Procedures of starting**

*The procedures of starting available are:*

**BEGINNING** (cf [U4.11.01] and **CONTINUATION** [U4.11.03])

*At least one of these two procedures must be obligatorily present in the file of order. No other Aster order must precede them. If it is the case or if none is present, the execution will be stopped as of the creation of the JDC. These are the procedures which contain*

*information on the procedure (PAR\_LOT=' OUI' or "NOT") which conditions the mode of execution of the orders which follow.*

*In fact macro-orders supervisor, with their construction, call routines FORTRAN allowing to initialize calculation by the following tasks:*

*·  
"connection" of the logical units of the standard files,*

*·  
opening of the data bases,*

*·  
reading of the catalogue of elements.*

*The first task consists in putting in correspondence numbers of logical units of files of input/output standards (message, error, result).*

*The second task consists to define and open the data bases (file of direct accesses used by the manager of memory) in accordance with the instructions of the user, who can redefine parameters of these files (see documents [U4.11.01] and [U4.11.03] on the procedures of starting). One invites for that the routines of initialization JEVEUX (see document [D6.02.01] it Manager of memory, JEVEUX).*

*The sequence of the orders to be carried out ends obligatorily in the order END. The text*

*who follows FINE must be commentarisé (i.e. begin with #). For a file included, it is order RETURN which marks the end of the instructions that ASTER must take into account.*

*Instruction manual*

*Author (S):*

*C. Key DURAND*

*:*

*U1.03.01-E Page*

*: 7/14*

*Note:*

*In interactive mode, seized of the manual controls, not to put of order END and to pass the argument interact on the line of ordering of tender of the job.*

*2.6*

*Bonds with EFICAS*

*The core of the supervisor is common with Efficas, the editor of command files Aster. At the time of the edition of a command file, this one carries out the syntactic analysis and the checks of coherence of the concepts by construction of the JDC and its STAGE objects. Efficas does not realize of course*

*not the task of construction of the macro-orders which would require the source code of Aster.*

*3*

*The process control language*

*3.1*

*Python and the language process control*

*A command file for Code\_Aster is exclusively made up of Python instructions.*

*first of the constraints is thus to conform to the rules of this language. One will be able to read the tutorial*

*Python (www.python.org) or many books of introduction to Python for more detail, but it is not necessary for the use of Aster.*

*A command file can contain instructions python of two natures: orders Aster and... any other instruction python. Indeed, a command file is one program python with whole share and one can place in particular there structures of control (loops), numerical tests (yew), calculations, calls to functions the pre one and postprocessing.*

*Within the framework of a “traditional” use of the code where the command file contains exclusively orders Aster, the two rules specific to Python to be retained are:*

.

*No the indentation on the first line of declaration of an instruction.*

*email = LIRE\_MAILLAGE ()*

*One should place neither white, nor tabulation before the character string email.*

.

*Arguments of the functions, in other words the key words of the orders, are separated by commas; they are composed of a key word, sign “=”, contents of the key word.*

***Important:***

*Editor EFICAS allows to produce only command files of this type: container exclusively orders ASTER, without another instruction Python. Utiliser EFICAS guarantees primarily three things:*

.

*the produced file will have a correct syntax python,*

.

*the produced orders will be coherent with the catalogue of orders,*

.

*the produced concepts being correctly connected (not of use of a concept without it was created by a preceding order).*

*The user having composed his command file thus will be safe from one stop to the execution with the reason*

*of a problem of syntax.*

## 3.2

### ***Concept of concept***

***Definition: one calls concept the structures of Aster data, that the user can handle and to name. These concepts are typified at the time of their creation and could be used only like argument of entry of the type corresponding in a further order.***

***The concept of concept thus makes it possible the user symbolically to handle objects and independently of their internal representation (which it can not know). Moreover, the python object indicated by the name of the concept any other information but its type, its class with the direction does not contain***

***python (cf Doc. D). Its name, transmitted by the supervisor to FORTRAN, makes it possible Aster to find***

***corresponding structure of data in the total base. But it is not possible to have visibility structure of data since the command file. For example, following instructions do not allow to print the structure of data of the grid type and name email:***

***mail=LIRE\_MAILLAGE ()***

***print email***

***but generate the following message:***

***SD grid name: email***

***There is an exception to this rule: tables. Indeed, an artifice of programming allows to simply recover information contained in a structure of data COUNTS while handling this one like a table at two entries:***

***to print all the table: print***

*resu*

*to print a value:*

*print*

*resu ["DX", 1]*

*to assign it to a variable: value = resu ["DX", 1]*

*That supposes of course that the structure of data resu, type COUNTS, was already calculated with moment when this instruction is met: thus in procedure step by step (PAR\_LOT='NON').*

*Lexical remark:*

*The names of concepts should not exceed 8 characters. Alphanumerics are licit (small letters and capital and figures not placed in first position) like the underscore "\_". Breakage is important: the concepts "EMAIL" and "Email" could be used in the same command file and will be regarded as different... it is however disadvised for the legibility of the file!*

### *3.3 Operations*

*possible*

*The structure of the process control language is appeared as a linear succession of instructions. In addition to the instructions python other than of the Aster orders, of which it is not question for moment, three natures of instructions (or orders) are available:*

- *the operator who carries out an action and who provides a produced concept of a preset type exploitable by the following instructions in the command set,*
- *the procedure which carries out an action but does not provide a concept,*
- *the macro-order which generates a sequence of instructions of the two preceding types and who can produce zero, one or more concepts.*

*Typically, an operator will be an ordering of assignment or of resolution, a procedure will be an ordering of impression (in a file).*

*From the syntactic point of view an operator presents himself in the form:*

*nomconcept = operator (arguments...)*

*Instruction manual*

Author (S):

**C. Key DURAND**

:

*U1.03.01-E Page*

: 9/14

*Whereas a procedure arises in the form:  
procedure (arguments...)*

*The syntax of an operator or a procedure is described in the following paragraph.*

### **3.4**

***Rules on the concept produced by an operator***

#### ***3.4.1 Guiding principle***

***With each execution of an operator, this one provides a new produced concept of the preset type in the catalogue of order.***

***The concepts appearing in argument of entry of the orders, are not modified.***

#### ***3.4.2 Produced concept and re-used concept***

***One calls re-used concept, a concept which being produced by an operator, is modified by one new occurrence of this operator or by another operator.***

***The use of a re-used concept is not possible, like exemption of the guiding Principle that from two conditions:***

.

***authorization given, by the catalogue and the programming of the order, to use reusable concepts for the operator: the reentrant attribute of the catalogue is worth “O” or “F”,***

.

***request clarifies of the user of the re-use of a concept produced by the attribute***

*reuse=nom\_du\_concept in the arguments of the orders which allow it.*

### **3.4.3 Checks carried out by the supervisor on the concepts produced**

*Produced concept respecting the guiding principle:*

*The supervisor checks that the name of the produced concept is not already allotted by one of preceding orders, in particular by an ordering of a preceding execution in the case of a CONTINUATION or a INCLUDE.*

*Concept used in re-use:*

*The supervisor checks that:*

*- the name of the produced concept is already well allotted.*

*- the operator is well entitled to accept re-used concepts,*

*- the type of the concept is in conformity with the type of concept produced by the operator.*

*Examples with accompanying notes:*

**BEGINNING ()**  
**concept=operator**  
(  
)  
#  
(1)

*is correct: one definite the concept,*  
**concept=operator**

(  
)  
#  
(2)

*is incorrect: one tries to redefine it*

#

*concept but without the statement,  
concept=operator (reuse = concept) # (3)*

*is correct, if the operator accepts*

#

*existing concepts and if the type is*

#

*coherent; it is incorrect if the operator*

#

*does not accept them.*

*END ()*

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

*HT-66/05/004/A*

---

*Code\_Aster* ®

*Version*

*7.4*

*Titrate:*

*Process control supervisor and language*

*Date:*

*07/04/05*

*Author (S):*

*C. Key DURAND*

*:*

*U1.03.01-E Page*

*: 10/14*

*In fact a concept can be created only once: what means to appear sign on the left = (equal) without reuse is employed in the arguments of the order.*

*In the case of a re-use, to again specify the name of the concept behind the attribute reuse is redundant; more especially as the supervisor checks that the two names of concept are identical.*

*Note:*

*One can destroy a concept, and thus re-use his name then.*

*3.5*

*Body of an order*

*3.5.1 Introduction*

*The body of an order contains the “variable” part of the order. The declarations are separated by commas and separately the attribute reuse mentioned above, they all are of the form:*

*[mot\_clé] = [argument]*

*The key word is necessarily a key word of the pending order, declared in the catalogue of this one.*

### **3.5.2 Word**

#### **key**

*A key word is a formal identifier, it is the name of the attribute receiving the argument.*

*Example: STAMP =...*

*Syntactic remarks:*

*.  
the order of appearance of the key words is free, it is not imposed by the order of declaration in catalogues,*

*.  
the key words cannot exceed 16 characters (but only the first 10 characters are meaning).*

*There are two types of key words: single-ended spanner words and the key words factors which differ by nature of their arguments.*

### **3.5.3 Argument of a single-ended spanner word**

#### **3.5.3.1 the type of the arguments**

*The basic types recognized by the supervisor are:*

- entireties,*
- realities,*
- complexes,*
- texts,*
- logics,*
- concepts,*
- as well as the lists of these types of bases.*

*The entireties and realities correspond exactly to the equivalent types in python.*

*.  
Optional single-ended spanner word awaiting a reality:*

*Catalogue*

*: VALE = SIMP (statut=' f', typ = "R"),*

*Command file*

*: VALE = 10.*

*,  
.*

*Optional single-ended spanner word awaiting an entirety:*

## ***Catalogue***

***: INFORMATION = SIMP (statut=' f', typ = "I"),***

***Command file***

***: INFORMATION = 1***

***,  
Instruction manual***

***Author (S):***

***C. Key DURAND***

***:***

***U1.03.01-E Page***

***: 11/14***

***The representation of the complex type is a "tuple" python containing a character string indicating the mode of representation of the complex number (parts real and imaginary or modulates phase) then numerical values.***

## ***Catalogue***

***: VALE\_C = SIMP (statut=' f', typ = "It),***

***Command file***

***: VALE\_C = ("IH", 0.732, -0.732),***

***Command file***

***: VALE\_C = ("MP", 1. , -45. ),***

***The two notations are strictly equivalent. In notation "MP", the phase is in degrees.***

***The text type is declared between simple dimensions. Breakage is respected. However, when a key word***

***must take a value in a preset list in the catalogue, the use wants that this value is***

*today always in capitals.*

*Catalogue*

*: ALL =SIMP (typ= `TXM', into= ("YES", "NOT")),*

*Command file*

*: ALL = "YES",*

*Breakage is important and, in the context above, the line of following order will fail:*

*Command file*

*: ALL = "yes",*

*The logical type is not used today in the catalogue of orders.*

*The concept is declared simply by its name, without dimensions nor quotation marks.*

### *3.5.3.2 Concept of list*

*Caution:*

*the word "list" is an abuse language here. It is not a question of the type "lists" python but rather of tuples, within the meaning of python: different the items is declared between an opening bracket and a closing bracket; they are separated by commas.*

*The lists are homogeneous lists, i.e. whose elements are of the same basic type. All basic type can be used in list.*

*Examples of list:*

*list entirities*

*(1, 2, 3, 4),*

*list text*

*("this", "is", "one", "list", "of", "text"),*

*list concepts*

*(resu1, resu2, resu3),*

*Facility of employment:*

*It is allowed that a list reduced to an element can be described without bracket.*

*Example of erroneous list:*

*Heterogeneous list of entirety and reality*

*(1,*

3,  
4.)

### **3.5.4 Key word factor**

*Certain information cannot be given overall (in once in the order), it is thus important to envisage the repetition of certain key words, to be able to affect arguments to them different. The key word factor offers this possibility; under a key word factor, one will thus find one together of key words (simple), which could be used with each occurrence of the key word factor. That makes it possible moreover to improve the legibility of the command file by gathering key words which*

*divides a common direction: for example various parameters of the same material.*

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

*HT-66/05/004/A*

---

*Code\_Aster ®*

*Version*

*7.4*

*Titrate:*

*Process control supervisor and language*

*Date:*

*07/04/05*

*Author (S):*

*C. Key DURAND*

*:*

*U1.03.01-E Page*

*: 12/14*

*Contrary to the single-ended spanner word, the key word factor can receive one type of object: the object supervisor “\_F”, or a list of this one.*

*That is to say the key word factor has only one occurrence and one can write for example, with the choice:*

*IMPRESSION =*

*\_F (*

*RESULT =*

*resu, UNIT = 6),*

*or*

```
IMPRESSION = (_F (  
RESULT =  
resu, UNIT = 6),),
```

*In the first case, the key word factor IMPRESSION receives a \_F object, in the other, it receives one singleton. Attention with the comma; in python, a tuple with an element is written: (element,)*

*That is to say the key word factor has several occurrences, two in this example:*

```
IMPRESSION = (_F (  
RESULT =  
resu1, UNIT = 6),  
_F (  
RESULT =  
resu2, UNIT = 7)  
),
```

*The number of occurrence (minimum and/or maximum) waited of a key word factor is defined in catalogue orders.*

*Concept of default value*

*It is possible to make affect by the supervisor of the default values. These values are defined in the catalogue of orders and not in FORTRAN.*

*There is no distinction from the point of view of the routine associated with the order between a value provided by the user and a default value introduced by the supervisor. This appears at the time of impression of the orders user by the supervisor in the file of messages: all them default values appear in the text of order, if they were not provided by the user*

*Recall: one cannot give default value to a concept.*

**4**

*Definition of values and evaluations of expressions*

*It is possible to assign values to variables python in order to use those like arguments simple key words: these variables are called parameters in EFICAS. They can contain values whole, real, complex, texts or lists of these types.*

*Example:*

```
Young = 2.E+11  
chechmate
```

=  
**DEFI\_MATERIAU**  
(**ELAS = \_F (E = Young, NAKED = 0.3)**)

*At the end of the execution, the context python is safeguarded with the base. Thus, in the continuation which will follow, the parameters will be always present, with their preset values, just like the concepts ASTER.*

*It is possible to carry out operations in python on the simple arguments of key words:*

**Pisur2 =**  
**pi/2.**  
**chechmate**  
  
**= MA\_COMMANDE (VALE = Pisur2)**

**or:**

**VAr**  
**=**  
**,**  
**world'**  
**chechmate**  
**= MA\_COMMANDE (VALE =**  
**pi/2.**  
**,**  
**VALE2**  
**=**  
**Pisur2+cos (30.)**  
**,**  
**TEXT = `hello'+var**  
**)**

***Use of python in the command files***

***It is not necessary to know the language python to use Code\_Aster. Indeed, realising some basic rules to respect on the indentation and parenthesizing, only the knowledge of process control language describes in the catalogues of order is necessary. And still, EFICAS allows to exempt itself to resort to the catalogue or the paragraph “syntax” of the orders in proposing the key words graphically to inform.***

***However, the advanced user will be able to use cheaply the power of the language PYTHON in sound command file, since this one is already written in this language.***

***The four principal uses can be: the writing of personalized macro-orders, the use general instructions python, the importation of useful modules python, the recovery of information of structures of Code\_Aster data in variables PYTHON.***

**Note:**

***If one wants to use French characters accentuated in the command file or them imported modules, it is necessary to place the following instruction in first or second line of file:***

***# \* coding: iso88591 \****

***In python 2.3, the absence of this line causes a warning which will become an error in python 2.4; in ASTER, it is systematically an error.***

***5.1 Macro-orders  
personalized***

***See the document [D5.01.02]: To introduce a new macro-order***

***The personalized macro-orders are very easy to program. They can be used for to capitalize recurring diagrams of calculation and thus to constitute a tool-trade. It is strongly advised to take example on the existing macro-orders: macro package in bibpyt.***

## 5.2

### *General instructions PYTHON and useful modules*

*The advanced users can benefit great from the use of loops (for), of tests (yew), of exceptions (try, except) and in a general way of all the power of the language PYTHON directly in their command file. The list of the uses is impossible to establish exhaustively. Many examples are present in the cases tests of the base of tests. One can for example to make adaptation of grid while placing the sequence calculation/mending of meshes in one buckle, to establish a criterion of stop of the iterations by a test on a computed value.*

*Concerning the exceptions, only the errors of the <S> type are recoverable as an exception in the command set. That authorizes for example “to try” an order then to begin again hand if this one “plants” while raising this exception.*

*In a loop, if an already existing concept is recreated, it is necessary to think of destroying it as a preliminary by order TO DESTROY.*

*The other various functionalities of python interesting for the user of Code\_Aster can to be:*

- the read-write on file,*
- numerical calculation (for example by using Numerical Python),*
- the call via the module bone with the language of script, and in particular the launching of a third code (os.system)*
- the handling of character strings*
- the call to graphic modules (grace, gnuplot)*

#### ***Recovery of computed values in variables PYTHON***

***To exploit the language PYTHON in its command file is not interesting that if one can conditionally to launch actions according to what the code calculated.***

***Certain footbridges exist between python and the structures of data calculated by the code and present in memory JEVEUX. Others remain to be programmed; this is a field in evolution and of future developments are awaited.***

***It is essential to understand that to recover calculated data requires that the instructions involving their obtaining were indeed carried out as a preliminary. In other words, it is essential to carry out the code in mode PAR\_LOT='NON' (key word of the order BEGINNING). Indeed, in it case, it does not have there total analysis of the command file, but each instruction is carried out sequentially. When one arrives on an instruction, all the concepts preceding thus have it already summer calculated.***

***Here some access methods to the structures of data. The list is nonexhaustive, to refer to documentation [U1.03.02].***

*Introduction and precautions for use*

*In Code\_Aster, the majority of the orders are programmed in FORTRAN. Structures of produced data are accessible only via the manager from memory JEVEUX, him even written in FORTRAN. In a standard execution of the code, only names of the concepts (and not of objects carrying themselves calculated information) are transmitted to the level of the supervisor, of order from order by the key words.*

*In a more advanced use of Python than the simple declaration of Code\_Aster orders, it command file written in Python can use the contents of the structures of data suitable for Code\_Aster. Indeed, Python can be used in the command files to create macro-orders and of the operations like loops (for, while,...), of the tests (yew,...), of external executions of orders (via the module bone), etc... The page "Use/Examples/ Examples of use of Python in Aster" of the Web site [www.code-aster.org](http://www.code-aster.org) gathers some a number of cases of application. It is then interesting for the user to recover the product of calculations FORTRAN in space python, i.e. its command file. Several methods Python were developed in order to reach the contents of other structures of data.*

*To recover calculated data (in memory JEVEUX), it is absolutely necessary that the instructions involving their obtaining were indeed carried out as a preliminary. In other words, it is*

*essential to carry out the code in mode `PAR_LOT='NON'` (key word of the order `BEGINNING` or `CONTINUATION`). Indeed, in this case, there is no total analysis of the command file, but each instruction is carried out sequentially. When one arrives on an instruction, all the concepts preceding it already were thus calculated.*

### ***BEGINNING (PAR\_LOT = "NOT")***

*It should then be noted that the command file thus produced is not readable by EFICAS which does not tolerate that files exclusively made up of orders specific to ASTER. Only variables simple (realities, entreties, strings) defined in declaratory mode (`a='toto'`) or algebraic (`n=3+4`) are readable by EFICAS.*

*The information read again in the memory JEVEUX, product of a preliminary calculation, can be exploited by example for (nonexhaustive list):*

- Enchaîner conditionally other orders (execution of loop while until obtaining a computed value of stress ultimate)*
- Manipuler in python of the contents of a table, a function, at ends of calculations*
- Récupérer attributes of a grid: list groups of nodes and meshes, co-ordinates.*

***2 Them***

**tables**

*The structures of data table are produced in ASTER by creation (CREA\_TABLE), by reading in a file (LIRE\_TABLE) or recovery in another concept (RECU\_TABLE). It is functionally heterogeneous tables of figures (whole, real, character strings) of which the columns are identified by names of label.*

*These are practical structures whose employment is generalized in the code. For example, majority of orders of postprocessing produce tables: to raise of the constraints in places geometrical given, to produce calculated macroscopic sizes (postprocessings of breaking process).*

*That is to say for example the table tab1 following exit of a calculation ASTER:*

**NODE NUME\_ORDRE DX**

**N2 14**

**0.93**

**N2 15**

**1.16**

**N1 3**

**0.70**

**N1 2**

**0.46**

**N1 1**

**0.23**

*It could also have been directly created like concept ASTER of the type counts by:*

**tab1=CREA\_TABLE (LIST = (**

**\_F (PARA=' NOEUD',**

**VALE\_K= ("N2", "N2", "N1", "N1", "N1"),),**

**\_F (PARA=' NUME\_ORDRE',**

**VALE\_I= (14,15,3,2,1),),**

**\_F (PARA=' DX',**

**VALE\_R= (0**

**.93,1.16,0.70,0.46,0.23),),)**

*One can directly recover an unspecified value of the table which one knows the access key (name of label of column) and the number of line:*

```
>>> print tab1 ["DX", 3]
0.70
```

*It is also possible to recover the totality of the table in the environment python via a class dedicated, produced by method EXTR\_TABLE, attached to the class of the concept ASTER:*

```
tab2 = tab1.EXTR_TABLE ()
```

*tab2 is an object python, authority of the Table class of the Utilitai.Table module. It is easy to handle with the methods associated with this class; one will be able to make help (Table) for to know the methods of this class.*

*The table tab2 could also have been directly defined by a dictionary:*

*From Utilitai.Table importation Counts*

```
listdic = [
{"NODE": "N2", "NUME_ORDRE": 14, "DX": 0.93},
{"NODE":
"N2"
, "NUME_ORDRE":
15, "DX":
1.
16},
{"NODE":
"N1"
, "NUME_ORDRE":
3
, "DX":
0.70,
},
{"NODE":
"N1"
, "NUME_ORDRE":
2
, "DX":
0.46,
},
{"NODE":
"N1"
, "NUME_ORDRE":
1
```

```
, "DX":  
0.23,  
},  
  
]  
listpara= ["NODE", "NUME_ORDRE", "DX"]  
listtype= ["K8", "I", "R"]  
tab2=Table (listdic, will listpara, listtype)
```

*The possible operations on tab2 are described hereafter.*

### *Instruction manual*

*: 4/10*

### *2.1 Impression*

```
>>> tab2
```

```
-----  
NODE  
NUME_ORDRE  
DX  
N2  
14  
9.30000E-01  
N2  
15  
1.16000E+00
```

```
N1  
3  
7.00000E-01  
N1  
2  
4.60000E-01  
N1  
1  
2.30000E-01
```

*Also possible:*

```
>>> print tab2
```

*Posting of only one parameter:*

```
>>> t.DX
```

```
-----  
DX  
9.30000E-01  
1.16000E+00  
7.00000E-01  
4.60000E-01  
2.30000E-01
```

*Order IMPR\_TABLE exploits the functionalities of impression offered by this class. interested reader will be able to read the programming python of this macro-order. In particular possibility of printing cross tables.*

*2.2*  
*Creation or impression of a under-table extracted by filter*

*Extraction according to only one criterion:*

```
>>> print tab2.NUME_ORDRE <=5
```

```
-----  
NODE  
NUME_ORDRE  
DX  
N1  
3  
7.00000E-01  
N1  
2
```

**4.60000E-01**

**N1**

**1**

**2.30000E-01**

***Extraction according to two criteria with logical association “&”/AND:***

**>>> print (t.NUME\_ORDRE < 10) & (t.DX>=0.3)**

-----  
**NODE**

**NUME\_ORDRE**

**DX**

**N1**

**3**

**7.00000E-01**

**N1**

**2**

**4.60000E-01**

***Extraction according to two criteria with logical association “|”/OR:***

**>>> print (t.NUME\_ORDRE < 2) | (t.DX<0.5)**

-----  
**NODE**

**NUME\_ORDRE**

**DX**

**N1**

**1**

**2.30000E-01**

**N1**

**2**

**4.60000E-01**

***Instruction manual***

***U3.0- booklet: Introduction to Code\_Aster***

*Author (S):*

**C. DURAND**, A. ASSIRE Key

:

U1.03.02-B Page

: 5/10

*Extraction of a restricted number of labels:*

```
>>> T ["DX", "NUME_ORDRE"]
```

```
-----  
DX  
NUME_ORDRE  
9.30000E-01 14  
1.16000E+00 15  
7.00000E-01 3  
4.60000E-01 2  
2.30000E-01 1
```

*Extraction according to a criterion of equality (here with value of the criterion deduced itself from the table)*

```
>>> t.DX == max (t.DX)
```

```
-----  
NODE  
NUME_ORDRE  
DX  
N2  
15  
1.16000E+00
```

## **2.3 Sorting**

*Sorting of the whole table according to a label:*

```
>>> t.sort ("NUME_ORDRE")
>>> T
```

```
-----
NODE
NUME_ORDRE
DX
N1
1
2.30000E-01
N1
2
4.60000E-01
N1
3
7.00000E-01
N2
14
9.30000E-01
N2
15
1.16000E+00
```

*For sorting according to several labels, the order of precedence being that in which the labels are declared,*

*it is necessary to write:*

```
>>> t.sort ("NUME_ORDRE", "NODE")
```

**2.4**

*Access to the values*

*The contents of the table accessible by the method are been worth () which produces a dictionary of which them*

*keys are the parameters of access of the table and the values the columns:*

```
>>> tab2.values ()
{"NODE": ["N1", "N1", "N1", "N2", "N2"], "NUME_ORDRE": [1, 2, 3, 14, 15],
"DX": [0.23, 0.46, 0.70, 0.93, 1.156]}
```

*The parameters are given by the attribute para (idem tab2.values () .keys ())*

```
>>> will tab2.para
["NODE", "NUME_ORDRE", "DX"]
```

**Simple access methods on the concepts**

**Access to the contents of a SD lists**

**lst = [lstr8]. Values ()**

**lst is a list python which contains the values of the Aster list: lst = [0. , 1.1, 2.3,...]**

**Access to the contents of a SD function or a SD tablecloth**

**lst1, lst2, (lst3) = [function/tablecloth]. Values ()**

**lst1 and lst2 are two lists python which contain the X-coordinates and the ordinates. If the function is complex, a third list is obtained and lst2 and lst3 will contain the lists of the real parts and imaginary.**

**lst1 = [function]. Absc ()**

**lst1 is the list of the X-coordinates, that is to say also the first list returned by Valeurs ().**

**lst2 = [function]. Ordo ()**

**lst2 is the list of the ordinates, that is to say also the second list returned by Valeurs ().**

*dico1 = [function]. Parameters ()*

*turn over a dictionary containing the parameters of the function; the type jeveux (FUNCTION, FONC\_C, TABLECLOTH) is not turned over, the dictionary can thus be provided to CALC\_FONC\_INTERP just as it is (see efica02a).*

*Evaluation of a SD function or formula*

*The functions in R and the formulas are appraisable simply in the space of name python, therefore the command file, as follows:*

```
FONC1=FORMULE (VALE=' (Y ** 2) +
X',
NOM_PARA= ("X", "Y",)),
```

```
);
>>> print FONC1 (1. , 2.)
5.
```

*or with a function:*

```
FONC2=DEFI_FONCTION (NOM_PARA=' X', VALE= (0. , 0. , 1. , 4. ,))
>>> print FONC2 (0.5)
2.
```

*Access to the contents of a SD grid*

*Two methods make it possible to recover the list of the groups of meshes and nodes of a structure of data of the grid type:*

```
[(tuple),...]
= [grid] .LIST_GROUP_MA ()
```

*return a list of tuples, each one containing the name of each group of meshes, the number of meshes which it contains and the dimension (0, 1, 2 or 3) highest of its meshes:*  
*tuple = ("GMA", Nb meshes, dim. meshes)*

```
[(tuple),...]
= [grid] .LIST_GROUP_NO ()
```

*return the list of the groups of nodes in the form:*

*tuple = (name of the group\_no, Nb of nodes of the group\_no)*

*:*

*U1.03.02-B Page*

*: 7/10*

*Access to the keys of a SD result*

*If EVOL is a structure of data result, then:*

*dictionary = EVOL.LIST\_CHAMPS ()*

*is a dictionary whose keys are the names of the fields  
who index the list of the calculated sequence numbers.*

*Example:*

```
>>> print dictionary ["DEPL"]
```

*(field DEPL is calculated with the numbers*

*[0,1,2]*

*of order 0, 1 and 2)*

```
>>> print dictionary ["SIEF_ELNO_ELGA"]
```

*(the field is not calculated)*

```
[]
```

*dictionary = EVOL.LIST\_VARI\_ACCES ()*

*is a dictionary whose keys are the variables of access*

*who index their own values.*

*Example:*

```
>>> print dictionary ["NUME_ORDRE"]
```

*(sequence numbers of result EVOL*

*[0,1,2]*

*are: 0, 1 and 2)*

```
>>> print dictionary ["INST"]
```

*(calculated moments of result EVOL*

*[0., 2., 4.]*

*are: 0.s, 2.s and 4.s)*

*dictionary = EVOL.LIST\_PARA ()*

*is a dictionary whose keys are the parameters of*

*calculation which indexes the lists (of cardinal equal to the number*

*calculated sequence numbers) their values.*

*Example:*

```
>>> print dictionary ["MODEL"]
```

*(name of the concept models reference*

*["MO", "MO", "MO"]*

*for each sequence number)*

```
>>> print dictionary ["ITER_GLOB"]
```

*(iteration count of convergence*

*[4,2,3]*

*for each sequence number)*

**4**

*Access method to an unspecified structure of data*

*It is possible, with the help of the knowledge of name JEVEUX of the object, to recover any vector or any collection presents in the memory.*

*Two methods are available: getvectjev (vector) and getcolljev (collection).*

*Access to a structure of data of the vector type*

*The method getvectjev gives access to a structure of data of the vector type. It applies always on the object "aster", and takes in argument the character string supplements (space y included/understood) defining the name of the object contained in the structure of data which one*

*wants to reach.*

*This one can be given thanks to the order Aster IMPR\_CO (CO = name).*

*Example: to recover the co-ordinates of the nodes of a grid named MA:*

*LMBO = aster.getvectjev (“MA .COORDO .VALE”)*

*Instruction manual*

*U3.0- booklet: Introduction to Code\_Aster*

*HT-66/05/004/A*

---

*Code\_Aster ®*

*Version*

*7.4*

*Titrate:*

*Method Python of access to the Aster objects*

*Date:*

*25/03/05*

*Author (S):*

*C. DURAND, A. ASSIRE Key*

*:*

*U1.03.02-B Page*

*: 8/10*

*Access to a structure of data of the collection type*

*In a similar way, the method getcolljev allows the consultation of the collections since python. It renvoit a dictionary whose keys are the names of the objects in the event of named collection, them numbers of index if not.*

*Example: to recover information concerning the connectivity of the elements of grid MA:*

*LMBO = aster.getcolljev (“MA .CONNEX”)*

*One obtains in this case a dictionary resembling:*

*{3: (2, 1, 5), 2: (6, 9, 10, 7, 11, 12, 13, 8), 1: (1, 6, 7, 2, 3, 8, 5)}*

*5*

*Recovery in python of the fields by elements and fields with nodes (EXTR\_COMP)*

*Method EXTR\_COMP, applied to a field, allows recovery in python of the contents of*

*field.*

*Example of use:*

*U = STAT\_NON\_LINE (...)*

```
U104 = CREA_CHAMP (  
TYPE_CHAM = "NOEU_DEPL_R",  
OPERATION = "EXTR",  
RESULT = U,  
NOM_CHAM = "DEPL",  
NUME_ORDRE = 104,  
)
```

*U104NP = U104.EXTR\_COMP ("DX", ["S\_SUP",])*

*print U104NP.valeurs*

```
V104 = CREA_CHAMP (  
TYPE_CHAM = "ELGA_VARI_R",  
OPERATION = "EXTR",  
RESULT = U,  
NOM_CHAM = "VARI_ELGA",  
NUME_ORDRE = 104,  
)
```

*V104NP = V104.EXTR\_COMP ("V22", [], 1)*

*print V104NP.valeurs*

*print V104NP.maille*

*print V104NP.point*

*print V104NP.sous\_point*

*Thus starting from the result U:*

*1) One creates a field (node or elXX) correspondent at one moment by CREA\_CHAMP.*

*2) One extracts the component by method EXTR\_COMP (declared for the cham\_elem and them cham\_no) which creates a new type of python object: post\_comp\_cham\_el and post\_comp\_cham\_no whose attributes are described hereafter.*

**: 9/10**

**Arguments of order EXTR\_COMP:**

**The order has 3 arguments:**

**ch1 = EXTR\_COMP (comp, lgma, topo=0)**

**comp**

**component of the field on the list lgma.**

**lgma**

**list groups of meshes, if vacuum then one takes all the group\_ma (equivalent with TOUT=' OUI' in the orders Aster.**

**topo**

**one reference of information on topology if >0 (optional, defect = 0).**

**Results of order EXTR\_COMP:**

**ch1.valeurs: Numeric.array containing the values**

**If there is request topology (topo>0):**

- **ch1.maille: number of meshes**
- **ch1.point: number of the point in the mesh**
- **ch1.sous\_point: number of under point in the mesh**

***Interface access to Code\_Aster: astk***

### ***Summary:***

***This document presents astk (contraction of Aster and Tk, to pronounce “astek”), the interface making it possible to organize its calculations Aster.***

*One describes the logic of operation of astk, the graphic interface itself, bsf which makes it possible to explore them*

*files on the various waiters, then it is explained how the user can configure astk according to its needs.*

*Lastly, on a concrete example, one shows how to use astk to make a study, an overload, to launch one list case-tests.*

*For the people having access to the waiter of calculation Aster of network EDF, one explains how to reach cards of experience feedback (REX), and, developer, tool of the AGLA (data processing department Aster).*

*The functionalities of astk version 1.2 are described here which supports versions 6 (starting from the STA6.5), 7 and 8 of Code\_Aster.*

*Version 5 is not supported by astk.*

***1***

***General presentation and concepts***

***The provision of a tool as Code\_Aster which functions on multiple platforms require a graphic interface to simplify the work of the user.***

***In addition, the evolution of the centralized means of calculation and the diffusion into free of Code\_Aster have***

***need the development of a portable product whose architecture can adapt to different computer set-ups.***

***astk is the graphic interface which makes it possible to organize its Aster calculations: to prepare its data,***

***to organize the files, to reach the tools the pre one and postprocessing, to launch and follow the evolution of***

***calculations. astk also makes it possible to choose the version of Code\_Aster to be used among those available***

***(STA, NEW...). Only versions 6 and following are supported by astk.***

***The name “astk”, to pronounce “astek”, comes from the contraction from Aster and Tk which is the bookshop***

*graphics used (as asterix was resulting from Aster and X for X Windows).*

## **1.1 Starting**

*To launch the interface, it is enough to type in a terminal: astk*

*In general, the order was placed in the way by defect of the users, the interface opens with a configuration by defect (see [[§ 4](#)] [Configuration](#)).*

*If the order is not found, it is necessary to launch: [to install\_dir] /ASTK\_CLIENT/bin/astk where [to install\_dir] is the repertory of installation of astk (contact possibly your administrator).*

*Access to the waiter of calculation Aster (EDF and people receiving benefits)*

*On the waiter of calculation Aster of EDF, to use the /aster/outils/astk order. It is advised with units EDF to install the interface on a departmental waiter.*

## **1.2 Functionalities**

*STUDY: astk makes it possible to launch an Aster calculation on the local machine (for example within the framework of one use on micro-computer), a waiter of departmental calculation or on the waiter of calculation Aster of EDF-R & D (access restricted to EDF and its people receiving benefits of studies).*

*OVERLOAD: The diffusion of the source code of Code\_Aster authorizes each one to test its clean developments. astk makes it possible “to overload” the code, i.e. to add or modify files sources, to create a particular version and to use it on case-tests or for studies. One can thus to create and use the new achievable ones, catalogues of orders or elements, and modules python.*

*TESTS: It is often judicious to test that its own developments do not impact the code in addition; astk makes it possible to easily launch a list of case-tests with a personal version.*

*AGLA: To the developers of the version of reference EDF, astk offers the access to the data processing department*

*Aster, AGLA, which makes it possible to organize the collaboratif development of the version of development (to avoid the conflicts, to ensure nonthe regression...).*

*REX: To make live the code passes by the taking into account of the remarks, needs, opinions of the users.*

*Cards of experience feedback can be emitted and consulted by the users since the interface, the developers can answer it (access to necessary waiter EDF).*

:

U1.04.00-C Page

: 5/34

*MULTI-MACHINES: Files necessary to its various actions (files of grid, source, results...) can be distributed on various machines on the network (declared in *astk*), *astk* ensuring the transfer and compression/decompression.*

*The passage of a firebreak is not proposed.*

*TOOLS: The user can launch various predefined tools and configure those which it needs (maillor, tool for postprocessing, editor...).*

*BSF: A navigator is provided (called *bsf*, box of selection of files), it allows to traverse them filing systems of the definite distant machines and to carry out current operations on files: copy, suppression, renaming, impression, or to open a window of orders on these machines.*

*ASJOB: One can follow calculations, their state (in particular in the case of launching in batch) since the window "Followed by the jobs", also called *asjob*.*

## **1.3**

### **Operating mode**

*Architecture client/server authorizes a clear separation between the interface (customer) and the tools used*

*to reach the code (services). It makes it possible to use the whole of scripts of the AGLA to manage version of reference in batch and *as\_run* (cf Appendix 1), a service *astk*, for the other versions available in room or on the network.*

*The communications protocol between the various machines is *rsh* or *ssh* for the orders Shell and CCP, SCP or *rsync* for the copy of files.*

**Example:** *The customer (i.e. the interface launched by the order ask) request launching of a calculation on a waiter of calculation.*

*The interface carries out a service on the waiter in question (order rsh or ssh) by indicating them to him parameters necessary to calculation (contained in a profile, [to see \[§ 1.5\]](#)). [The service](#) takes then in charge the operations necessary: to repatriate the files necessary to the calculation of different machines towards the waiter of calculation, launching of calculation, return of the files results...*

## **1.4 Waiters**

### **ask**

*For ask, a waiter is:*

- is a waiter of Aster calculation: a machine on which one can find the part “waiter” of ask, i.e. the whole of the services which give access the code; one will be able to launch calculations via this waiter and to use files on this waiter for a calculation,*
- is a file server: one will be able simply to use files on this waiter at the time of one calculation.*

*The waiter called “Room” is in fact a file server (only information of connection are necessary for a file server, but on the local machine, one knows them easily).*

*If one wishes to launch calculations on the local machine (on which are installed a version of Aster and the waiter part of ask), it is also necessary to declare this machine like a waiter of calculation (Local and*

*Machine in the following example).*

U1.04.00-C Page

: 6/34

**Example of configuration:** ([see \[§ 2.1.2\]](#))

*astk is used on the machine of name mach00, on which Code\_Aster is installed. One has access to a departmental file server file01, the files of this waiter is accessible (assembly NFS) since two machines of calculation comp02, comp03. One has also access to a cluster with NR nodes of calculation whose frontal machine is front04.*

*One has then:*

- “Local” (reserved label): one has it always to explore the files which are on mach00;*
- “Machine” (label unspecified, the procedure of installation fixes this name at the value turned over by the order `uname N `): whose address IP is that of mach00 which is the waiter of calculation (services astk installed) of the local machine;*
- “Departure” (unspecified label): whose address IP is that of file01, which allows to explore the files lodged by the file server, configured like a waiter of calculation Aster (services astk installed) having comp02 and comp03 seen like nodes of calculation (comp0i can be the same machine as file01);*
- “Cluster” (unspecified label): whose address IP is that of front04 which is a waiter of calculation (services astk installed) having NR nodes, the only machine accessible being front04.*

*The difference between “Departure” and “Cluster” is that in general the stations of calculation are accessible directly (one could thus subject a calculation in interactive on one or the other), whereas for a cluster, the users see only the frontal machine in general, distribution being made on the nodes by a sequencer of batch processings.*

*One can as well have several waiters of calculation “Departure” or “Cluster” that not to have only the station “Local+Machine”.*

## **1.5 Profile**

### **astk**

*A profile astk is a file which contains all information relating to your study, your overload, etc: the site of the files of the study, in data, result, the type associated with each file, parameters of tender of calculation (memory, time, machine of calculation, interactive batch/...), in case of overload, the site of the source files, achievable, the catalogues produced...*

*The profile also contains parameters on the interface itself to resume a study exactly in the same state that it had been left.*

*The profile is recorded on request of the user (finely Fichier/Enregistrer or To record under...) and with each launching of a calculation.*

*For the users of asterix: the profile astk includes the profile of study and execution to the direction asterix, and the parameters of tender which were not stored in asterix. The file, even if it remains with ASCII format, is despite everything more complicated to read.*

## ***Description of the graphic interface***

*The graphic interface (IHM) breaks up into 4 parts:*

*1) A bar of menu*

*2)*

*mitres*

*3) Parameters of tenders*

*4) The bar of state*

*1.*

*2.*

*4.*

*3.*

**[Appear 2-a: Principal window](#)**

## **2.1**

### **Bar of menu**

The menu “Assistance” also makes it possible to reach the description of the menus.

#### **2.1.1 Menu**

##### **File**

- *Nouveau*: Allows to create a new profile.
- *Ouvrir*: Open a profile created before by ask. One cannot open the profiles created by asterix in this way.
- *Enregistrer*: Safeguard the profile running (this is made automatically during the launching of one calculation).
- *Enregistrer under*: Safeguard the profile running while giving the choice of the name of the profile and sound site.

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

*Author (S):*

**Key COURTEOUS Mr.**

:

*U1.04.00-C Page*

: 8/34

· *Copier under*: Copy the profile running in another repertory and proposes to copy the files (in data and/or results) that it reference.

· *Importer:*

- *asterix*: Reads again a file *.pret* or *.prex* produces by *asterix* (the contents of the *.pret* being less rich, final improvements will be probably necessary, to consult *INFORMATION*).
- *astk\_serv*: Reads again a file *.export* of a preceding execution (or the file *\*.pNNN* of repertory *\$HOME/flashor*).
- *Exporter under*: Allows to export the profile running to the format *astk\_serv* (for the services *ASTK\_SERV*).
- *Impression*: Configuration of the orders of impression  
The user defines orders of impression (*lpr*, *a2ps*...) who will be used to print files, and files of impression (printing). The order can be carried out on one distant waiter.  
For the code *@P* of the line of order the name of the file of impression will be substituted, the name of file will replace *@F* (see [§ 2.1.3] for the field codes).  
Example of ordering of impression:  
*lpr - H - P @P @F*  
or */usr/bin/a2ps - P @P -2 --print-anyway=yes --sides=tumble @F*
- *Quitter*: Finish the session
- The *NR* the last open profiles are directly accessible starting from small *Fichier*.

## **2.1.2 Menu Configuration**

- *Serveurs*: Allows to modify the configuration of the waiters: waiters of calculation or waiters of file.
  - For the waiters of calculation, to choose the mode of remote loading of the configuration *Aster*: waiter turns over the list of the versions available, the procedure (batch and/or interactive) and associated limits.  
It is necessary to indicate the “login” authorized to connect itself to the waiter, and the repertory where is installed  
waiter part of *astk* (*ASTK\_SERV*).
  - For the file servers, to choose “any” like mode remote loading of configuration *Aster*.
- *Interface*: Defines the preferences of the user:  
For *astk*:  
Name, first name, email will be used for the bond towards the management tool of the experience feedback  
(emission, consultation of the cards anomalies, evolution... ).  
The access to the functions of the data processing department *Aster* if the user is recognized as developer *Aster* on the machine of reference.

*The access path to the editor and the terminal (window xterm) on the local machine, the version with to select by defect, the number of remanent profiles in the small File, the level of message (debug), the domain name network of the machine and if mode DHCP (addresses IP dynamics) is active, the communications protocols used for the orders Shell (rsh or ssh) and copies it files (CCP, SCP or rsync).*

*For the follow-up of the jobs:*

*The number of lines posted during the consultation of a calculation in the course of execution (tail), and the automatic frequency of actualization in minutes.*

## **2.1.3 Menu**

### **Tools**

· *Paramètres: Allows to configure the launching of the tools.*

*Certain tools are envisaged out of standard (without inevitably being available on the local machine):*

- *bsf: Explorer of files multi-machines,*
- *Eficas: Editor of command file Aster,*
- *Gibi: Maillor and tool for postprocessing (usable free with Aster),*
- *GMSH: Maillor and tool for postprocessing (free),*
- *Stanley: Tool for postprocessing integrated into Aster,*
- *Foresys: Tool for navigation in sources FORTRAN.*

*When one chooses Stanley throw, astk seeks in the profile the bases available (by order preferably a base in result, if there is not, a bhdf (HDF bases) in result, if not one base in data and finally, a bhdf in data), produces a temporary profile starting from the profile*

running with a command file Aster which starts with CONTINUATION () and which launches STANLEY ().

The user can add his own tools, to parameterize the access path to the tools (including to modify the ordering of access to the standard tools), to define in which types of files associate the tool and to specify if one can use the tool on a distant file.

The following codes can be used in the line of order:

- @F: absolute way of the selected file,
- @R: repertory containing the selected file,
- @f: name of the file (without the repertory),
- @D: address DISPLAY (that known at the time of the launching of the interface).

The tools are called either starting from small Outils, or starting from the contextual menu on a file of a list or in the explorer (right button).

To select a file, it is enough to click on its name in a list (in the Etude mitre, Tests or Overload).

While double-clicking on a file, association between the type of the file and the tool to be used rest on extension of the file name for the bsf, whereas the type selected by the drop-down list (cf. description of the mitres) prevails in astk.

## **2.1.4 Menu**

### **Options**

#### **· Arguments:**

Allows to position optional arguments which will have placed on the line of order of execution of Code\_Aster.

dbgjeveux: activate a mode different from the management of the objects in memory to detect them crushings and destruction of objects,

rep\_outils: the repertory defines where the tools called since Aster (onmetis are sought or gibi for example),

rep\_dex: the repertory defines where are sought the external data (given grid),

rep\_mat: the repertory defines where the data of the catalogue material are stored.

#### **· Paramètres:**

Definition of the optional parameters used during the launching of a list of tests (button TESTS).

nbmaxnook: a maximum number of invalid case-tests (NOOK, ARRET\_ANORMAL...) before the stop list of the tests,

cpresok: allows to choose which are the tests of which one keeps the files result,

RESOK: one keeps the files of tests OK and NOOK,

RESNOOK: one keeps only the files of tests NOOK,

facmtps: multiplicative factor of the time of the tests (compared to the time of reference of will.para).

Useful, for example, when one subjects tests with achievable built in debug mode, more

*slow.*

## **2.1.5 Menu**

### **Help**

- *Introduction/Small Parameters of calculation/: access to the text of assistance*
  - *Historique of the modifications: Evolution of astk to the wire of the versions, new possibilities, corrections carried out, known anomalies...*
  - *Frequent Problèmes: Some questions frequently put with their solutions.*
  - *Fenêtre of the messages: The messages of information <INFO>, of <ERREUR> errors are written in this window. With a level of message equal to or higher than 1 (see [[§ 2.1.2](#)]), [one obtains more or less of information.](#)*
- Level 3 posts the orders subjected to the waiters, levels 4 and 5 make it possible to have complementary details in the file .o (of debug type) during the execution of as\_run (in interactive); what makes it possible to include/understand sometimes why an error occurs.*
- *By the way: the impossible to circumvent window of information.*

## **2.2**

### **mitres**

*One finds five buttons in this zone. One speaks about mitre because the contents which one finds under the buttons changes according to that which is in a hurry. Graphically, they are not “truths” mitres bus the widget does not exist in standard the Tk bookshop (and one did not want to add pre-necessary additional!).*

*STUDY, TESTS and OVERLOAD are mitres in which one informs the list of the files necessary; AGLA and REX are buttons which can use the contents of the other mitres.*

*Lastly, the check box located beside the first four buttons announces that one uses (or not) it contents of the associated mitre.*

*Examples: To launch a study, the mitre STUDY should be notched. To call upon the functions of the AGLA (on the machine of reference), mitre AGLA should be notched; one will note that in this case, TESTS and OVERLOAD are automatically notched because their contents are taken into account.*

### **2.2.1 Mitres STUDY, TESTS, OVERLOAD**

*To reach the files more easily, to traverse the tree structures more quickly (files being often gathered in close repertories), or to simplify the posting of the names of files, one can define a basic way.*

#### **Appear 2.2.1-a: Basic way**

*One defines it while clicking on the Parcourir button and one chooses the repertory which will be the repertory by defect.*

*Each mitre contains a list of files (two lists for OVERLOAD).*

#### **Appear 2.2.1-b: List files/repertories**

*Key COURTEOUS Mr.*

*:*

*U1.04.00-C Page*

: 11/34

*One defines a file or repertory by line. One finds left towards the line:*

- *Type: type of the file or the repertory;*
- *Serveur: name of the waiter on which is the file/repertory;*
- *Nom: access path to the file: in absolute if it starts with “/”, into relative compared to basic way in the contrary case;*
- *UL: logical number of unit associated this file;*
- *D, R, C: check boxes to indicate if the file/repertory is respectively in data, result, compressed (with gzip).*

*When one changes the type of a file/repertory, default values are positioned for indicators D, R, C and the logical number of unit.*

*Notice on the types:*

*Code\_Aster handles the files via the procedures FORTRAN which use numbers of logical unit (file fort.19 for example); it thus affects numbers of unit logic by defect to simplify the life of the user. The “type” thus makes it possible to reach easily with the numbers used by defect; it as makes it possible astk to check as the user provides coherent data (for example which one provides well one repertory for such type, or which one does not provide two objects whereas only one is authorized for such other...).*

*To handle the list, one has four buttons:*

- 
- : allows to add a new virgin entry at the end of the list;*
- 
- : allows to add a file/repertory at the end of the list by traversing the tree structure of files;*
- 
- : to remove the line currently selected in the list;*
- 
- : open the file/repertory currently selected in the list with the editor of the waiter where the file (cf [§ 4.1] is). If it is about a repertory, all the files of the repertory are opened with the editor (attention with the repertories containing many files or files binary not éditables!).*

*Arguments (mitre STUDY and TESTS only):*

*This zone of text makes it possible to transmit arguments to achievable Aster. See also [§2.1.4].*

*Finely contextual:*

*While clicking with the right button on an entry of the list, one reaches a contextual menu:*

- *Ouvrir: launch the tool associated with this type of file (determined by the “Standard” field, and not the extension of the file), if no tool is associated this type, one publishes the file;*
- *Editer: publish the file (or all the files of the repertory) in the same way as it button*
- ;
- *Imprimer: print the selected file;*
- *Ouvrir with...: one can choose to open the file selected with one of the tools available (the result can be astonishing if the tool does not know this type of file!);*
- *Default values: the interface determines a file name per defect according to “Standard” selected starting from the name of the profile (file .astk), no value is proposed if the profile was recorded yet (is used in general on a virgin line only one has just inserted, indicators D/R/C are not affected by this operation);*
- *Propriétés: post the permissions, the size, the date and the hour of the file (order ls -).*

## *Mitre OVERLOADS*

*The data (source files) are provided in the higher list, whereas them results (achievable, catalogues compiled) are provided in the lower list.*

*dat:*

*file result containing of the curves to format XMGRACE*

*PS:*

*File postscript*

*agraf:*

*file result containing the data for Agraf (old versions of Aster*

*wrote the directives and the data in the same file that it was necessary to cut out with the order post\_agraf on the machine of reference)*

*digr:*

*file result containing the directives for Agraf*

*rmed:*

*file result with format MED*

*unv:*

*file result with the “Universal” format (IDEAS)*

**para:**

*file of parameters (retranscription of the parameters of calculation for the tests)*

**repe:**

*result and/or data directory (makes it possible to transmit/recover the contents complete of a repertory; as one does not affect numbers of logical unit Aster must reach the files by their names, cf orders DEF1\_FICHER)*

**libr:**

*file or repertory with the choice of the user*

**btc:**

*script of launching generated by the service (one can thus recover it, to modify it...).*

*At the time of a astout on the machine of reference, resu\_test must be on this one.*

### **2.2.1.2 Lists types for TESTS**

**list:**

*file containing the list of the tests to be carried out (a name of test per line without .com m)*

**rep\_test:**

*repertory containing the data files of the tests (orders, grid...)*

**resu\_test:**

*repertory where the files results are recopied*

**btc:**

*idem STUDY*

### **2.2.1.3 Lists types for OVERLOAD, part GIVEN**

**F:**

*sources FORTRAN*

**C:**

*sources C*

**py:**

*python sources*

**capy:**

*sources of the catalogues of orders*

**cata:**

*sources of the catalogues of elements, options, sizes...*

**hist:**

*file histor (historical of the modifications)*

**conf:**

*file of configuration (choice of the options of compilation, the bookshops...)*

**unig:**

*file unigest containing the modules to be removed*

**datg:**

*geometrical data*

*cmat:*  
*catalogues of data materials*

*In general, one provides a repertory for the first five types (sources); all the files of which the extension corresponds to the type indicated are taken into account. Nevertheless, it is disadvised mixing*

*types of files in the same repertory.*

*hist, unig, datg and cmat are exclusively related to the management of the version of reference.*

*forlib is used only on the machine of reference.*

### **2.2.2 Button**

## **AGLA**

*This button gives access the functions of the data processing department which coordinates the actions of developers of the version of coherence. For that, the box on the right of the button must be notched, it who causes automatically to take into account the contents of the mitres TESTS and OVERLOAD, it is then enough to click on the button "Throw". One will refer to the handbook of the AGLA ([D1.02.01]) for more details on the various actions.*

- ASNO: allows "to note" modules (to announce that one envisages to restore one modification), applies to the source files and the files of test.*
- ASDENO: allows "to indicate" modules. This action does not use any the data of TESTS or OVERLOAD. When one clicks on "Launching", a window requires to choose the type of module to be indicated (fortran/C, python, catalogues or test), and to indicate the name of modules separated by a space, a tabulation or a return to the line (without the extension: op0191 to indicate the file op0191.f). For the files Python, it is necessary of to specify the name of the repertory (package in the denomination Python) in which they find (bus contrary to sources FORTRAN and C, the same name can be used in different repertories), example  
: macr\_recal\_ops@Macro (indicates the module macr\_recal\_ops of the Macro package).*

### [Appear 2.2.2-a: Fenestrate ASDENO](#)

- ASQUIT: provides in the file output the list of all the noted modules.*
- ASVERIF: check that a whole of sources can be integrated in the version of reference (compliance with the rules of programming, file histor present...).*
- PRE\_EDA: it must be carried out before the meeting of the team of development, the developer thus announce its intention to restore sources, PRE\_EDA raises the points which will have to be regulated in meeting of development (PRE\_EDA carries out a ASVERIF and a passage of tests provided in the profile).*

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

*HT-66/05/004/A*

**Date:**

**05/04/05**

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U1.04.00-C Page**

**: 14/34**

*· ASREST: it is about the ultimate phase of the restitution which consists of a ASVERIF, one passage of the tests of the list of nonregression, the code return must be lower or equal to 2 so that the restitution is taken into account.*

*· FORLIB creation/suppression: allows to produce/remove a bookshop for the tool FORESYS (on the machine of reference).*

### **2.2.3 Button**

**REX**

**Notice**

*This part will be deeply modified during 2005 with the change of the tool of management of the experience feedback.*

*This button gives access the management tool of experience feedback (on the machine of reference).*

**It**

*is decontaminated when the machine of reference is not in the list of the waiters.*

*· Choix of the correspondent: The user must choose his Aster correspondent among those which him are proposed. The Aster correspondent validates the cards emitted by his front users that they are examined by the team of development (it filters the problems thus already known or solved...). The developers are their characteristic corresponding, for them, this choice of [small is thus decontaminated \(see also \[§ 2.1.2\]\).](#)*

*· Emettre a card without joining the profile: This function makes it possible the user to emit one card-index experience feedback to point out an anomaly in Code\_Aster (AI: anomaly software), to ask for an evolution of Code\_Aster (EL: evolution software), in one of the tools associated (Mongrel, Lobster, Efficas, atsk, bsf...) (AO: anomaly outil/EO: evolution tool), one modification of documentation (ED: evolution documentation), or a request for expertise in modeling (AOM: contribute to the optimization of modeling).*

*· Information relating to the transmitter of the card is accessible by the menu Configuration/Interface. The files contained in the profile running are not joined to card-index, which can make very difficult the treatment of the card. It is advised to use "to emit a card and to associate the files it".*

*· The version of Code\_Aster indicated is that selected in the interface (Parameters of calculation).*

- *Emettre a card and to associate the files it: This function makes it possible to emit the same type of card that the preceding one, this time the data included in the profile are joined to card-index. For an anomaly, the files to reproduce the error should always be provided.*
- *What does not prevent the user from trying to insulate as much as possible the problem met, in particular to try to join a study on a model which requires little of memory and of computing time!*
- *Consulter cards: The window of consultation of the cards comprises a line where one defines search criteria, the filter makes it possible to carry out a research in the text of the cards (can be rather long) by using a regular expression.*
- *“To seek”*: the list of the cards refreshes;
- *“To visualize”*: open the cards selected in the list (one can also double-click on a card to visualize it);
- *“To print”*: print the contents cards selected in the list;
- *“associated Files”*: if the selected card has associated files, this opens a bsf where these files are;
- *“associated Study”*: if the selected card has associated files, this makes it possible to import directly profile associated with the card;
- *“To print the list”*: print the list of the posted cards.
- *Fiches to be corrected: For the developers only. One finds the same window of consultation of the cards with predefined criteria which correspond to the cards that it developer must treat. An additional button “final Answer” allows him to answer the card (after having submitted it to the team of development).*
- *Supprimer a card: Allows to remove a card which is still in the state EMIS\_UA/EMIS\_CUA by that which emitted it.*

## 2.3

### **Parameters of tender**

*The parameters of calculation are provided in the right part of the principal window.*

## Appear 2.3-a: Zone of the parameters of calculation

*One defines the quantity of memory used for the job (in megabytes), the maximum time of calculation (in seconds, minutes: seconds or hour: minutes: seconds).*

*One chooses on which machine calculation is carried out, the version of Code\_Aster used, if calculation is*

*subjected in batch or interactive.*

*debug/nodebug: for a study without overload, one specifies which achievable one wishes to use (under reserve that both are available); at the time of an overload, one chooses to compile with or without information of debug.*

*The button “Throw” carries out the actions according to the notched mitres.*

*The button “Followed by the jobs” opens the window described afterwards.*

### **Operating mode** (for a STUDY):

*During the launching of a study (with or without overload), a button of option is available to side button “Throw”. Three modes of launching are available:*

- “run”: carry out the study (traditional operation),*
- “dbg”: launch the study by using the debugger,*
- “pre” : prepare the repertory of work without carrying out the study.*

*When one selects “dbg” or “pre”, the mode “debug” is chosen by defect.*

## **2.4 Bar of state**

*The zone of text located all in bottom of the principal window provides of the assistance when one sails in menus, or when the pointer passes to the top of the buttons of the interface. During the launching of a calculation, the operations in progress are posted here.*

### [Appear 2.4-a: Bar state](#)

## **2.5 Follow-up of the jobs**

*This window provides information on the state of launched calculations, which appear in the form of one list.*

*“To publish” breaks up into “File output” and “File error” which gives access to the messages envoys by the job on the standard exit (stdout) and the exit of error (stderr). A double-click on one job of the list also posts the file output.*

*“To remove” erases the selected jobs of the list, the files related to this job in the flashor and calculation stops if this one is not finished.*

*“To bring up to date” questions the waiters on which calculations are in progress. The check box allows to reactualize automatically at a frequency defined in Configuration/Interface.*

*“To seek” allows to consult the last lines of the file message of a job in progress of execution (it does not do anything on a finished job). One can use the zone of text “Filters” not to post that lines containing the character string indicated.*

### **Innovation**

*One finds the same functions in the contextual menu which appears while clicking with right button on one or more jobs. One can thus bring up to date one job among several not finished.*

*Each line corresponds to a job, one finds 13 columns:*

- The number of the job (in batch), number of the process in interactive*
- The name of the job (name of the profile for a study, an overload, or name of function AGLA)*
- Date of tender*
- Heure of tender*
- State of the job (HANGS, RUN, SUSPENDED, ENDED)*
- Diagnostic of job (OK, NOOK, <A>\_ALARME, <F>\_ERREUR, <F>\_ARRET\_ANORMAL...)*
- Nom of the tail in batch or “interactive”*

- *Temps CPU of the execution Aster*
- *Login on the waiter of calculation used*
- *Adresse of the waiter of calculation used*
- *Machine of calculation (name of the node for a cluster)*
- *Version of astk*
- *Indicateur interactive batch/*

*The diagnosis emitted by as\_run appears in English, because it is envisaged to translate them overall, but that was not carried out yet.*

### **3** *Limp of selection of files: bsf*

*bsf is a tool delivered with astk which can only be launched. It is about an explorer of files who allows to sail on the local machine, like a traditional explorer of files, and also on various configured distant waiters.*

*bsf uses the configuration of the waiters of astk, in particular the fields necessary to connection (addresses IP, login) and orders to open a terminal or an editor.*

*The reading of the configuration is made only with the starting of bsf, if one modifies the configuration in*

*astk, it is thus necessary to close the bsf then to open it again.*

## [Appear 3-a: bsf](#)

### **Note:**

*bsf does not treat the file names and repertories containing spaces (it results one from them shift in the names and the types of the following objects).*

*: 21/34*

### **3.1 Navigation**

***One finds two drop-down lists in the window of the bsf.***

***The first makes it possible to pass from a waiter to another, the second memorizes the list of the twelve last repertories where the user carried out an action (edition, copy...). The first entry of this list is “----- Direct -----”, which makes it possible to go directly in a repertory without traversing the tree structure.***

***Generally, when the required repertory does not exist, one turns over in the definite HOME for the current waiter.***

***One can configure this list and fix certain repertories (so that they remain present in the list) in clicking with the right button on [this one \(cf Appears 3.1-a\)](#).***

*.*

***: the contents of the current directory refresh;***

.  
: *go up with the repertory relative;*

.  
: *propose to create a new repertory in the current directory (and places itself in it new repertory);*

.  
: *open a terminal on the current waiter.*

*The bar of state gives indications on the significance of these buttons when the pointer of mouse passes to the top.*

## **3.2**

### ***Small File and finely contextual***

***One finds certain entries similar to the contextual menu of the files in the mitres (see [§2.2.1]): To open, Publish, Print, Open with..., Properties.***

***“To copy”:* allows to copy one or more files/repertories (shortened by CTRL+C).**

***“To cross”:* idem To copy, except that the original files will be removed (shortened by CTRL-X).**

***“To stick”:* carry out indeed the copy or the displacement of the files (shortened by CTRL+V).**

***“To remove”:* erase the selected files/repertories.**

***“New file/New repertory”***: respectively allow to create a file or one repertory in the current directory.

***“To carry out an order”***: give the possibility of carrying out an order in the repertory running, the current selection is proposed on the line of order, it is necessary to choose one of the shells available on the waiter.

### **3.3 Menu Posting**

***One can choose to post or not the files known as hidden (starting with “. ”) by notching the box envisaged.***

***bsf posts the repertories then the files, one alphabetically can Trier of the name or in function of the date in the normal or opposite order by modifying the options of the menu.***

***The preferences of posting are preserved if one selects “To record the preferences”.***

***U1.04.00-C Page***

***: 23/34***

### **4 Configuration**

***The first time that the user launches the interface, it has a configuration by defect which was defined at the time of the installation. The configuration is then stored in the repertory \$HOME/.astkrc.***

*If the user wants to return to the configuration of origin, it must erase this repertory and start again askt.*

### *Notice n°1*

*With each time one defines an order to be carried out (final, editor...), it is advised to show the absolute way (since the root) to prevent that the order that is to say not found if the variable \$PATH is incorrect.*

### *Notice n°2*

*In general, askt supplements the orders which need to post windows with the argument “- display SCREEN”, where SCREEN is the current price of the variable \$DISPLAY. If the order used does not accept this argument, it is enough to specify good syntax with the code @D which will be replaced by the current variable of \$DISPLAY (for example: mon\_editor - display=@D, cf Small Tools).*

*One can check the current price of \$DISPLAY, small Aide/Fenêtre of the messages: askt indicates in the first lines for example:*

*<INFO> Posting of the applications on mach00.domain.org: 0.0*

*It is this value which will be provided to the supposed distant machines to post a window on the machine customer.*

*The waiter part of askt (ASTK\_SERV) included tools simplifying certain tasks of the developers like the consultation of the source code or the update of a local version of development.*

*The file \$HOME/.astkrc/config thus contains two information necessary to contact machine of reference: the complete name of this waiter and the login of the user. This last must be defined in this file to avoid following alarm:*

*<A>\_ALARM remote connection may fail:*

*devel\_server\_user not defined in /home/xxxxxx/.astkrc/config*

## **4.1 Waiters**

*One reaches the window of configuration by small Configuration/Serveurs.*

### **Configuration/Waiters**

*The first button makes it possible to pass from a waiter to another and to add a “New waiter”.*

*The fields are:*

- Complete Nom or addresses IP: it is about the name of the waiter on the network; one can indicate sound complete name with the domain name (for example: linux.labo.univ.fr) or its address IP (by example: 156.98.254.36).*
- State of the waiter: one can put on “off” a temporarily inaccessible waiter.*
- Login: identifying with which one connects oneself to the waiter.*
- Répertoire HOME: repertory by defect when one arrives on this waiter with the bsf.*
- Répertoire of the services: repertory where are installed the services on this waiter (to indicate it complete way, for example: /aster/ASTK/ASTK\_SERV/bin), to leave vacuum for one file server.*
- Mode of remote loading of the configuration: no (for a file server), handbook (it is necessary to click on the button “To download now” to recover the Aster configuration of waiter), automatic (astk questions the waiter with starting every 30 days).*
- Dernier remote loading: date from the last update of information of configuration.*

- *Terminal*: order to open a terminal on the waiter. This makes it possible to open a window orders on the waiter when the *bsf* is used, and to follow a calculation (it interactivement terminal must accept the option *E* to carry out an order, *xterm* is appropriate).
- *Editeur*: editor text (for example, *nedit*). The procedure of installation chooses an editor among (and in this order): *nedit*, *xemacs*, *emacs*, *xedit*, *VI*.

The following values are turned over by the service *as\_info* (nothing for a file server) and thus depend on the configuration of the waiter part of *astk*:

- *Type of platform*.
- *Versions available*
- *Accessible Machines*: list accessible nodes of calculation since this waiter.
- *Interactive Batch/*: specify if the waiter accepts launching in batch, interactive and provides them limits in memory, time CPU, a number of processors fixed on the waiter. Seul LSF is supported like software of management of batch, the support of PBS is still incomplete and experimental.

## **4.2 Interface**

**: 26/34**

*This window makes it possible to inform personal information of the user, to choose the language used by the interface.*

*For those which have access to the machine of reference, authority AGLA is posted (EDA for developer, UTL for user...). For the EDA, the organization and the name of the correspondent are automatically filled. The users must do it themselves.*

*Then, one finds the version which will be selected by defect, the orders to reach one terminal and an editor (as for the waiters).*

*“A Many profiles in small Fichier” make it possible to preserve the name of the NR the last open profiles so as to point out them quickly.*

*“Level of message” indicates the level of details of the messages written in the window of messages of the menu Helps. Niveau=0: only the messages <INFO> and <ERREUR> are written; higher levels allow debugger the behavior of the interface. Level 1 is advised, it allows to see the error messages being able to appear at the time of the problems of communication with distant waiters.*

*One must then specify the domain name network of the machine. For example, domain.org if it complete name of the machine is mach00.domain.org. If the domain name is left empty, one message of alarm is posted with starting because the distant machines are likely not to be able to contact the local machine mach00 with its short name. The name of the machine such as it will be used by the distant machines is indicated in the field Nom Customer. If mode DHCP is active, it is in this field which one can indicate address IP of the local machine.*

*For the follow-up of the jobs, one can choose the number of posted lines when the file is visualized output in the course of job (button “To seek”), and the frequency of actualization of the list.*

### 4.3 Tools

*One selects the tool to be configured with the drop-down list, or a new tool is added. Standard tools are predefined (tiny the/capital ones are taken into account in the names tools). The tools are necessarily carried out on the machine “Room” (where the interface is launched).*

*In general, the tools are launched either on a file of a mitre (STUDY, TESTS or OVERLOAD), maybe on a file when one traverses the filing system with the bsf.*

*One defines simply the line of order necessary to the launching of a tool (absolute way advised), one can place the codes @F, @R, @f, @D in the line of order (see [§ 2.1.3]) for to correctly pass a file to the tool. One can put these codes between brackets to be able to launch the tool alone, without file in argument.*

*Types of files can be associated the tool. The type taken into account to launch the tool is extension when one traverses the files with the bsf, the type of the drop-down list when it acts of a mitre.*

*One can choose if the tool is usable on a distant file. In this case, astk is given the responsibility to bring back it file in question about the local machine in a temporary repertory, of launching the tool, then to redeposit the file on the distant waiter (even if it were not modified by the tool).*

### 4.4 Impression

*The orders of impression are defined by small Fichier/Impression.*

*On the same principle that the tools, one defines any ordering of impression (LP, lpr, a2ps...) who contains the code corresponding in the name of the file (@F, to see [§ 2.1.3]). @P is replaced by the name of the file of impression.*

*Here a traditional list of order using GNU a2ps:*

*Format 2 columns/page:*

*a2ps - P @P -2 - l82 --footer --print-anyway=yes --sides=tumble @F*

*Format 136 characters/line:*

*a2ps - P @P - R - l136 --columns=1 --footer --print-anyway=yes --sides=tumble @F*

*“Transparent” format:*

*a2ps - P @P - R --columns=1 --print-anyway=yes --sides=simplex @F*

*How to make a study?*

*In this paragraph, one describes stage by stage how to use astk to make a study.*

*The study consists in calculating the response in inflection of a bent piping. One has the elements following:*

- A command file Aster: demo01a.com m*
- The description of the geometry carried out with Gmsh: demo01.geo*
- Grid built by Gmsh: demo01a.msh*

*The following results are produced:*

- A file of grid Aster: demo01a.mail*
- A file result with the format Gmsh (fields of displacements, constraints...) : demo01a.pos*
- Traditional files of message and Aster result: demo01a.mess and demo01a.resu*

*In the example, one places all the files in the /home/tutorial/demo01 repertory.*

*Note:*

*In the case of a study with several command files, all the files must be*

*of type “comm”, associated the logical unit 1 and it is the extension which determines the order of execution: .com m, then .com 0, .com 1,..., .com 9 (there can be holes).*

## **5.1**

### **Creation of the profile**

*One launches the interface which opens on a virgin profile, or if astk is already launched, one chooses*

*New file/in the menu to create a new empty profile.*

*One places oneself in the mitre STUDY.*

## **5.2**

### **Selection of the files**

#### **5.2.1 Definition of a basic way**

*In the mitre STUDY, one chooses a basic way to simplify the access to the files.*

*One clicks on the icon*

*, the /home/tutorial/demo01 repertory is chosen.*

#### **5.2.2 Addition of existing files**

*One adds the command file while clicking on*

*, the selection of file opens directly*

*in the basic way which one has just defined. It only remains to select the file demo01a.com m (double-click or simple click + ok), and the file appears in the list. Let us note that astk identifies the type of*

*this file starting from its extension “comm”, the logical number of unit is positioned to 1, the box “D” (given) is notched.*

*One makes in the same way for the file of grid to the format Gmsh (demo01a.msh). astk recognizes the extension “msh”, the logical number of unit is positioned to 19, the box “D” is notched.*

#### **5.2.3 Addition of files...**

*Except if an execution already took place, the files results do not exist yet, one thus cannot to add by traversing the tree structure.*

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

## **Author (S):**

**Key COURTEOUS Mr.**

**:**

**U1.04.00-C Page**

**: 28/34**

### **5.2.3.1... while inserting a blank line**

**The grid with the Gmsh format will be read again and converts in the command file Aster by order PRE\_GMSH in grid with the Aster format. One can recover this grid by adding one file of the type “email” on the logical unit 20.**

**One clicks on**

**, a line is added in the list. One chooses the type “email” in the list (what has for effect to position the logical number of unit to 20). The name is indicated /home/tutorial/demo01/demo01a.mail or demo01a.mail or ./demo01a.mail (since one can indicate the name of the file into relative compared to the basic way). The file is produced by the execution, one thus notches the box “R” (result) and one strips “D”.**

## **Notice**

**Order PRE\_GMSH uses by defect numbers 19 and 20 with inputs/outputs, if one modifies the command file to read again or write the files of grid on other units, it is necessary to be coherent for the numbers indicated in astk.**

### **5.2.3.2... with “Default value”**

**One could continue thus to add the other files, but one will use the function “Value by defect” for the following files. This function uses the name of the profile astk to build them default values (see [[§ 2.2.1 /Menu contextual](#)]), one thus will record the profile.**

**One chooses Enregistrer under... in small Fichier, one goes with the navigator in the repertory /home/tutorial/demo01, and in the line Selection, one types demo01a (the extension .astk is automatically added).**

**Let us note that the title of the principal window of astk gives the name of the current profile. The title is now: ASTK version 1.2.1 - demo01a.astk - /home/tutorial/demo01**

*One inserts a blank line while clicking on , one chooses the type of file “pos”, then one clicks with the right button in the box of the one and file name chooses “Default value”: astk builds one file name starting from the name of profile (by withdrawing the extension) and of the type “pos”, is /home/tutorial/demo01a/demo01a.pos. Moreover, astk tries to substitute the basic way for more legibility, one sees as follows: ./demo01a.pos. The box “R” was notched, and the logical number of unit fixed at 37. Let us suppose that in the file of order, one indicated:*

*IMPR\_RESU (UNITE=30,...)  
one thus modifies the logical number of unit consequently, it is enough to click on the old value, of to erase and to type 30. Only two digits are posted in this box, to avoid the errors, astk check that the numbers of logical unit lie between 1 and 99.*

*In the same way, one adds a file of the type “mess” and one of type “resu” in this manner (of leaving them numbers of logical unit per defect).*

#### **5.2.4 To remove a file**

*To remove a line of the list of the files, it is enough to select it while clicking in the zone where one indicates the name of the file and to click on the icon*

**Note:**

*Only the reference to this file in the profile astk is forgotten, the file itself is not erased!*

: 29/34

### 5.3 *Launching of calculation*

*The files given and results are selected, one adjusts the parameters of calculation ([see \[§ 2.3\]](#)), and one clicks on the button “Throw”.*

*One takes care to notch the box which is just beside STUDY to announce that one wishes to use the contents of this mitre... if not interfaces it answers us “Nothing launching! ”. If the profile were not recorded yet, the interface requires to choose a place and a name for it [profile \(see \[§ 5.2.3.2\]\)](#).*

*astk calls the service which carries out calculation, and transmits to the Follow-up jobs (asjob) the number of the job*

*(number of the process in interactive) and other information which will make it possible to follow advance*

*calculation. The initial state of calculation east HANGS (on standby), when calculation starts, it becomes RUN, then*

*ENDED when it is finished (other states are possible in batch). The button “To bring up to date” calls the service which refreshes the state of calculations in progress.*

*When calculation is finished, one can consult the output of the job while double-clicking on the job, or by*

*To publish/File output.*

### 5.4 *Consultation of the results*

*One can consult the files results simply while double-clicking on their name, which opens one text editor for the files “mess” and “resu”; on the file of result to the Gmsh format, “pos”, that causes to open this file in Gmsh directly. One visualizes the deformation thus and isovaleurs (provided Gmsh were installed, and that “pos” is in the types of files associated Gmsh, to see [\[§ 4.3\]](#)).*

### 5.5 *Use of the tools*

*One can also use astk and the fact that one can freely define tools in it to gather in a profile all files necessary to a study even if those are not directly used by Code\_Aster.*

*In this example, demo01a.geo is a file that Code\_Aster cannot read again; it contains description of the geometry, Gmsh uses it to create the grid (.msh).*

*One can nevertheless insert it in the profile (button*

*), to affect an unspecified type to him (“libr” by*

*example) since it will not be used during the execution (boxes D, R not notched). One can directly open the geometry by making Ouvrir with... /Gmsh (click right on the name of file), to modify the geometry or the parameters of the grid, to re-mesh and record the grid.*

*One can then start again calculation on the new file demo01a.msh.*

*Obviously, this is not limited to Gmsh; one can use other tools (maillieurs, tool of postprocessing, graph plotter...) directly since astk and to reach all the files thus of a study since a profile with the adequate tool.*

**6**  
*How to carry out an overload?*

*One considers in this paragraph that the user is familiar with handling of the lists of files in the mitre STUDY.*

*An overload consists to add or modify part of Code\_Aster and to use it to carry out one study. The objective of an overload is to produce achievable, a compiled catalogue of orders and/or a catalogue of elements. One can also overload the methods python defined by Aster, in this case, the sources is recopied in the repertory of execution (it does not have there a receptacle*

*object of overloaded files python).*

*One places oneself in the mitre OVERLOADS.*

## **6.1**

*Addition of the sources*

*One proceeds like adding files for a STUDY. One can select is a file, that is to say a repertory. It is often clearer and more practical to place its source files in repertories.*

*If one adds a repertory in the list of the sources (left higher the mitre OVERLOADS) type “F” (files FORTRAN), all the files whose extension is .f will be compiled and used to make new achievable.*

## **6.2**

*To define the results of the overload*

*Files C (standard “C”) and FORTRAN (standard “F”) make it possible to build achievable: type “exec”.*

*The catalogues of orders “capy” make it possible to build a catalogue of orders compiled: type “cmde” (repertory containing the files cata.py and cata.pyc).*

*The catalogues of elements, options and sizes “cata” are used to produce a catalogue compiled elements: “ele”.*

## **6.3**

*Taking into account of the overload*

*So that the data well informed in the mitre OVERLOAD are taken into account, it is necessary to notch*

*the box located just on the right of the button OVERLOADS (the mitre OVERLOAD is always notched in this paragraph).*

*One needs a receptacle in result absolutely corresponding to the data sources (“D” notched). If there are repertories “C” and/or “F” in “D” onnée, one needs a “exec” in “R” résultat; of even for “capy” with “cmde” and “cata” with “ele”.*

*One can prepare the overload independently of the study (advised) or make the overload and to launch the study in the tread.*

### **6.3.1 To prepare the overload alone, then to launch a study**

*To prepare the overload alone:*

- to strip the mitre STUDY*
- to put the sources in “D” onnée*

- *to only put the corresponding receptacles in “R” é sultat*
- *“To launch”.*

*The overload builds the results (achievable, catalogues...) starting from the data (sources).*

*Launching of the study by using this overload:*

- *to notch the mitre STUDY*
- *to strip the indicator “D” for the sources*
- *to put the réceptables in “D” onnée only*
- *“To launch”.*

*Instruction manual*

*U1.0- booklet: Introduction to Code\_Aster*

*HT-66/05/004/A*

---

*Code\_Aster ®*

*Version*

*7.4*

*Titrate:*

*Interface access to Code\_Aster: astk*

*Date:*

*05/04/05*

*Author (S):*

*Key COURTEOUS Mr.*

*:*

*U1.04.00-C Page*

*: 31/34*

*The products of the first stage are then used as data to launch the study.*

*Caution: Not to strip OVERLOAD, if not the study will be launched with the standard version not overloaded.*

*It is rare that compilation succeeds with the first test, by separating the two tasks, one sees immediately if compilation occurs badly, or if the achievable one is not produced.*

*6.3.2 To make the overload and to launch the study at the same time*

*To connect the two stages automatically:*

- *to notch the mitre STUDY*
- *to put the sources in “D” onnée*
- *to put the corresponding receptacles in “D” onnée and “R” é sultat*
- *“To launch”.*

*In the event of problem of compilation, it may be that achievable is produced without taking in count part of the data sources. It is thus necessary to look at the output attentively of compilation. For that, the step of the preceding paragraph is advised.*

7  
*How to launch a list of tests?*

*It is necessary to approach this point after the two precedents. Indeed, throw a list of tests does not have of interest that to validate an overload is with respect to nonthe regression of the functionalities original of the code, that is to say on a whole of case testing a new functionality.*

*To use this possibility, it is necessary to notch the box located just on the right of the button TESTS (what strip STUDY automatically). In the majority of the cases, one uses an overloaded version, therefore in this case the mitre OVERLOAD is also notched.*

**Notice n°1**

*It is absolutely necessary to prepare the overload independently of the launching of test as with the § “Preparing the overload alone, then to launch a study”. One prepares overload, then one launches the tests with the results of this overload.*

**Notice n°2**

*On the machine of reference, the launching of a list of tests must be made only in batch.*

*The data are very simple, one provides a file of the type “list” (see [[§ 11](#)]); “rep\_test” indicates where are the files necessary to the launching of the tests (“given” of the tests: .com m, .mail...); “resu\_test” makes it possible to write the results of the tests in another repertory.*

## **8 Questions frequent**

***“Nothing occurs when one tries to launch a calculation, to publish a file or to open one terminal on a distant waiter” or “Code return = 2, Profiles Copy failed in the window messages with the launching of a calculation”***

*It is probable that the local machine cannot communicate correctly with the waiter distant. Communications using protocol CCP/rsh, the files .rhosts on the local machine and on the distant waiters must be correctly well informed. If one uses protocol SCP/ssh, it is necessary that the private and public keys are coherent.*

*One can check it by leaving astk, and by starting again it in this manner:*

*astk --debug 0 - check (--debug 0 is used to limit the impressions)*

*To attentively see information which is printed. astk provides information on the variable of environment DISPLAY (to check that it is correctly defined), and tests connection between machine where is launched astk and distant waiters. In the event of problem of connection with one waiter, astk suggests a modification of the file .rhosts of the target machine.*

***“When a calculation in batch is subjected, there is the message: The number of the job and the class do not have not been able to be recovered”***

*Time or the required memory is probably beyond the limits of the classes of work. See in the window of the messages, there is probably a message of the manager of batch of the style “Cannot exceed queue' S hardware limit (S)”.*

*To decrease time or the memory, or explicitment to choose a class batch which agrees in additional options.*

***“While clicking on Default value the file name remains empty”***

*This function uses the name of the profile to determine a default value, it is necessary to record the profile before being able to use this function.*

***“On the machine of reference: the behaviors in batch and interactive are different”***

*It is possible. In batch, Code\_Aster is launched by scripts of the AGLA, in interactive, one rests on as\_run. To announce in a “AO” the differences.*

***Appendix 1 Use of the service as\_run (of ASTK\_SERV)***

***The reading of this chapter is reserved to the users who wish to launch Code\_Aster “to the hand”, without to use the interface and with those which installed and maintain a version local.***

***When one uses the interface astk for launching calculations, this one as a customer calls upon services suggested by a waiter which can be on the same machine or a distant machine (in the case where the waiter is distant, there are exchanges of files and a Shell order through the network (protocol rsh or ssh) that we do not detail here).***

*Several services are called by the interface:*

*as\_info: recover information of configuration of the waiter: versions and machines of calculation available, limits in interactive and batch;*

*as\_actu: recover the state of a calculation in progress or finished;*

*as\_tail: recover the last lines of the output of calculation (stdout, left standard);*

*as\_del: stop a calculation in progress and/or removes the files of the flashor associated with this*

*calculation;*

*as\_edit: open the file output of a calculation (file .o of the flashor) or error (file .e) in one editor;*

*as\_exec: launch the actions indicated in the profile in argument (file of the .export type).*

*as\_run is a service called by as\_exec within the framework of an execution via the interface, it is limited to*

*to launch an execution of Code\_Aster, with or without overload, a simple study or a list of tests.*

*The options of as\_run are given while typing: as\_run --help, one obtains:*

*use: as\_run action [options] [arguments]*

*Functions:*

*- Return the hand subroutine of has code\_aster command:*

*as\_run --gettop [options] order [.capy]*

*- Return current release number of the development version:*

*as\_run --getversion [options]*

*- Show has source slips by: FORTRAN, C, python, capy, cata, histor gold test:*

*as\_run --show [options] obj1 [obj2...]*

*- Copy has source slips by in current directory:*

*as\_run --get [options] obj1 [obj2...]*

*- Build has code\_aster version (achievable, libraries, catalogs):*

*as\_run --make [--version\_dev=VERS]*

*- Perform one gold several updates of has version development:*

*as\_run --update [options] fich1.tar.gz [fich2.tar.gz...]*

*- Download available updates from has server and apply them to the current development version:*

*as\_run --auto\_update [options]*

*- The execution described by the Carries out profiles (default action):*

*as\_run --run [options] profiles*

*options:*

*--version show program' S version number and exit*

*- H, --help show this help message and exit*

*- v, --verbose print status messages*

- F, --force force operations which edge Be cached (download, compilation...)

--remote\_shell\_protocol=REMOTE\_SHELL\_PROTOCOL

remote protocol used for Shell commands

--remote\_copy\_protocol=REMOTE\_COPY\_PROTOCOL

remote protocol used to Copy files and directories

--editor=EDITOR editor command

--devel\_server\_user=DEVEL\_SERVER\_USER

login one the development server (name/IP address is usually set in ASTK\_SERV/conf/config)

Options for maintenance operations:

--vers=VERS Code\_Aster version to used

- has, --all get all the files of the test

--version\_dev=VERS development version of Code\_Aster to update

- L, --room files will not been searched one has server drank one the room machine

--nolocal force remote files search (reverse of --room)

Additional precise details:

· One can create a bond towards as\_run for any action to simplify the call (this is especially useful for the actions get, show and getop which one often calls):

*get - > as\_run*

*One can then use get fichier.f instead of as\_run --get fichier.f*

*· When one recovers a source file with get, show or getop, this one are put in /tmp/astk\_`login`/cache. If for the same file again is asked, this one is taken directly in this repertory except if the option --force is activated; the files which have more one day are automatically removed mask.*

*· --room--nolocal: these two options make it possible to pass in addition to the value defined in file of configuration. If the mode by defect is to seek the files locally, one can use --nolocal to force research on a distant machine (it is in particular useful for to seek the updates of Code\_Aster on the www.code-aster.org waiter). Conversely, if one systematically recovers the files on a waiter of development in network, one must use --room to visualize source files installed on the machine local.*

*· The principal file of configuration is xxxx/ASTK/ASTK\_SERV/conf/config (where xxxx are it principal repertory of installation of Aster), the user can define certain values in \$HOME/.astkrc/config (where \$HOME is the repertory by defect of the user), in particular it name of user to use on the distant waiter (devel\_server\_user) to avoid an alarm with each launching of as\_run.*

*· --version\_dev is used by the actions make, update and auto\_update. Whereas --towards is used by get, show and getop.*

*1*

*To model a mechanical problem with Code\_Aster*

*The problem to be modelled is a thin cylindrical tank (thickness 0.02m, average radius  $R=1m$ ,  $L=4m$  height) subjected to a pressure interns variable with the height, corresponding to a pressure hydrostatic.*

*Being given symmetries of the geometry and*

*$R=1m$*

*loading, one chooses a modeling*

*two-dimensional axisymmetric.*

*It will thus be enough to represent a vertical section of this cylinder (in plan X Y)*

*The two stages to be envisaged are:*

***L=4m***

•  
***the creation of the grid***

•  
***the drafting of the command file***

2  
***Manufacture of the grid: what to envisage?***

y  
***Some is the software of grid used (GIBI, IDEAS, GMSH), it is necessary to envisage, as of the creation of the grid, of to name the entities which will be used in calculation to affect***

D  
C  
***elementary characteristics, conditions with limits, of the loadings, materials...***

***Indeed, although it is possible to use them directly numbers of nodes and meshes in the file of orders, it is preferable to use entities named. This makes it possible to have a command file ldf independent of the degree of refinement of the grid, and of a possible renumerotation of the nodes or elements.***

***In practice, these entities are groups: charg***

**: 3/10**

**3  
How to write its command file?**

**3.1  
To start from nothing?**

**When one wants to model a new thermomechanical problem, one does not leave in general white sheet: it is useful to take as a starting point a command file of a modeling close to that to treat. How to obtain these files? The sources are varied:**

**.  
the base of the tests of Code\_Aster, with its documentation, is often an important help, because it covers most of the functionalities of the code (one can find these tests in the repertory astest),**

**.  
the formations make it possible to know the whole of the orders thoroughly paying to types of modelings  
: statics linear, thermal, dynamic,**

*thermoplasticity, post\_traitement...*

*The drafting of this command file will be largely facilitated by using the editor of file of orders EFICAS.*

**3.2**

*Orders with the magnifying glass*

*We now will detail the orders necessary to the realization of calculation considered.*

*Command file*

*Explanations*

*# TITRATES thin Cylinder under pressure*

*The comments are preceded by sign #,  
hydrostatic*

*BEGINNING ();*

*Obligatory order to start...*

*PRE\_GMSH ();*

*The grid is with format GMSH*

*email = LIRE\_MAILLAGE ();*

*Reading of the grid in the file of grid,  
and creation of the concept email containing it  
grid with the format Aster*

*# Redefinition of the groups of nodes and  
groups of meshes*

*mail=DEFI\_GROUP (reuse =mail,*

*Definition of the groups of meshes from*

*MAILLAGE=mail,*

*those created in GMSH*

*CREA\_GROUP\_MA= (\_F (NOM=' APPUI',*

*GROUP\_MA=' GM11'),*

*\_F (NOM=' LDF',*

*GROUP\_MA=' GM13'),*

*\_F (NOM=' LFA',*

*GROUP\_MA=' GM14'),*

```
_F (NOM=' ND_A',  
GROUP_MA=' GM1'),  
_F (NOM=' ND_B',  
GROUP_MA=' GM2'),  
_F (NOM=' ND_C',  
GROUP_MA=' GM3'),  
_F (NOM=' ND_D',  
GROUP_MA=' GM4'),  
),);
```

### ***# Definition of the model***

***A model is a concept containing the types  
finite elements useful for calculation***

*And other files produced by calculation?*

## 5.1

*The file MESSAGE*

*This file contains the echo of the orders and gives additional information on the execution of each order:*

*for example MECA\_STATIQUE:*

```
# -----
# ORDERS NO: 0011 CONCEPT OF THE TYPE: evol_elas
# -----
res1=MECA_STATIQUE (CHAM_MATER=chmat,
MODELE=modl,
ANGLE=0,
NIVE_COUCHE=' MOY',
NUME_COUCHE=1,
SOLVEUR=_F (NPREC=8,
METHODE=' MULT_FRONT',
STOP_SINGULIER=' OUI',
RENUM=' METIS'),
INFO=1,
PLAN=' MAIL',
INST=0.0,
EXCIT= (_F (CHARGE=charg,
TYPE_CHARGE=' FIXE'),
_F (CHARGE=clim,
TYPE_CHARGE=' FIXE')),
);
```

*--- NUMBERS TOTAL NODES: 138 OF WHICH:  
12 NODES "LAGRANGE"*

*--- NUMBERS TOTAL EQUATIONS: 264*

*--- A NUMBER OF NONNULL COEFFICIENTS IN THE MATRIX: 2120*

*--- A NUMBER OF BLOCKS USE FOR STORAGE: 1*

## 5.2

*File GMSH*

*File GMSH (filled by IMPR\_RESU, format "GMSH") contains the data necessary to visualization.*

*In the same way for the other files of interface with software of graphic postprocessing (IDEAS, ENSIGHT)*

*or software of layout of curves XMGRACE.*

### 5.3

#### *Generation of the grid with GMSH*

*One proposes here the file geo allowing the generation of the grid with GMSH (software free and free).*

```
////////////////////////////////////  
// Grid of tank GMSH V1.60  
////////////////////////////////////
```

```
// Variables  
// Ray interns tank  
Rint = 1;  
// Thickness of the wall  
ep = 0.02;  
External // Ray of the tank  
Rext = Rint+ep;  
// Height of the tank  
H = 4;

Facts of the case*

*1.1 Geometry*

*The study relates to a piping including/understanding two right pipes and an elbow [Figure 1.1-a].*

*The geometrical data of the problem are as follows:*

- .  
length LG of the two right pipes is 3 m,*
- .  
the Rc ray of the elbow is 0.6 m,*
- .  
the angle of the elbow is 90 degrees,*
- .  
the thickness of the right pipes and the elbow is 0.02 m,*
- .  
and the ray external Re of the right pipes and the elbow is of 0.2 Mr.*

## ***1.2 Loading***

***The boundary conditions are as follows:***

***there is embedding on the level of section A,***

***The loading applied is a constant force  $FY = 100.000$  NR directed according to the axis Y and applied to the section B,***

## ***1.3 Characteristics material***

***The properties of material are those of A42 steel:***

***the Young modulus  $E = 204.000. E+6$  N/m<sup>2</sup>,***

***the Poisson's ratio = 0.3.***

## ***2 Modeling of the problem***

***One can model the problem by elements of hull DKT.***

### ***2.1 Grid GMSH***

***In the case of modeling in elements hulls, the grid consists of the discretization of surface average piping. Geometry being symmetrical compared to the plan (A, X, Y), one will net that a half surfaces. The grid will have to be sufficiently fine to obtain a solution specify (elements DKT with 3 nodes having an interpolation of order 1 out of membrane).***

**2.2 Orders**

**Aster**

**The right pipes and the elbow will be modelled by elements of hull (DKT).**

**Piping is embedded in its base, on all the nodes located in the  $Y=0$  plan. Piping present a symmetry plane  $Z=0$ .**

**.**

**An effort distributed  $F^*$  directed according to the axis  $Y$  and applied to the section  $B$ , (the effort**

*distributed is such as*

*2 Rmoy  $F^*$  = the total force which one wishes to apply).*

*One will calculate the stress field by element to nodes (SIGM\_ELNO\_DEPL), for each loading case. To use NIVE\_COUCHE to define the level of calculation in the thickness*

*The principal stages of calculation with Aster are:*

.

*Grid.*

.

*Definition of the finite elements used (AFFE\_MODELE).*

*One will use the groups of meshes resulting from the grid.*

.

*Definition and assignment of material (DEFI\_MATERIAU and AFFE\_MATERIAU).*

*The mechanical characteristics are identical on all the structure.*

.

*Assignment of the characteristics of the elements hulls (AFFE\_CARA\_ELEM) with in particular the thickness and the vector  $V$  defining the reference mark of examination (key word ANGL\_REP).*

*One can take for example  $V=Oz$ .*

.

*Definition of the boundary conditions and loadings (AFFE\_CHAR\_MECA).*

.

*Resolution of the elastic problem for each loading case (MECA\_STATIQUE).*

*Calculation of the stress field by elements to the nodes for each loading case (option "SIGM\_ELNO\_DEPL").*

.

*Impression of results (IMPR\_RESU).*

*One will print in form listing average displacement on the section B as well as the values maximum of the tensor of constraints.*

***Document: U2.01.02***

***Note of use of the boundary conditions  
treated by elimination***

***Summary***

***The treatment of the boundary conditions of the type Dirichlet value of ddl imposed by elimination does not offer***

*even flexibility that by dualisation. This treatment is to be used when one seeks to improve times of execution of a calculation (although at present, the profit is not guaranteed) or if one wishes to use positive definite matrices of rigidity.*

*Let us note that all the types of boundary conditions available in AFFE\_CHAR\_\* (\* = meca/ther/acou) cannot be eliminated and treated by AFFE\_CHAR\_CINE.*

*Instruction manual*

*U2.01 booklet: General concepts*

*Author (S):*

*J. Key PELLET*

*:*

*U2.01.02-A Page*

*: 2/6*

*1*

*Principle of elimination used*

*One seeks to solve in RN the problem of minimization under constraint (Pb1) according to:*

*Min  $1 C Ku - C F$  with:  $U = U RN, U$*

*= U*

*G*

*0*

*2*

*G*

*U UG*

*where*

*uo RP is known (Ipn)*

*.*

*$G$  is the subset of  $NR = \{1, \dots\}$*

*$N$ , of cardinal  $p$ :  $G = G$*

*$G$*

*$1 \dots$*

*$p$*

*$\cdot$*

*$U$*

*$uI$*

*$I iG$*

*$G$  is the projection of  $U$  on under space generated by*

*$\cdot$*

*where  $(ui) J = ij jN$*

*$\cdot$*

*$K$  is a symmetrical matrix  $N \times N$ ,*

*$\cdot$*

*$F RN$  is fixed.*

*The constraint  $uI = U$*

*$G$*

*0 or not represent boundary conditions of the homogeneous Dirichlet type.*

*If one notes  $L = C G$ ,*

*$NR$*

*the complementary one to  $G$  in  $NR$ , one can, using the previously definite  $ui$ ,*

*$U$*

*to break up  $RN$  all in all direct of  $VG =$  vector space generated by  $I iG$  and of  $VL =$  space*

*$U$*

*vectorial generated by  $I$  it;*

*Consequently, we have  $RN = VG VL$*

*and one notes  $U = uG uL$  where  $uG = uI$  and  $U$*

*$G$*

*$L = uIL$*

*$uG$*

*that is to say still in vectorial notation  $U = U$*

*$L$*

*The problem (Pb1) can thus be written in the form of the problem (Pb2):*

*Min  $1 C K$*

*$U + 1 C K$*

*$U + C K$*

*$U - C F - C F$*

**G**  
**GG**

$U$

$G$

$0$

## *2 Treatment*

*in*

*Aster*

### *2.1*

*The loads kinematics*

*A kinematic load (standard Aster: char\_cine\_\* [\* = meca/ther/acou]) makes it possible to characterize the unit G of the imposed ddl and them (u0) I for I G which are the values assigned to these ddl.*

*The definition of a kinematic load is done via operator AFFE\_CHAR\_CINE for (u0) I constant or functions of the geometry or time.*

## 2.2

*The vectors kinematics*

0

*The vectors kinematics are*

U

*cham\_no\_\* which represents the vectors*

0

*stored in*

*the order of classification under unclaimed to the problem.*

*With each kinematic load corresponds a kinematic vector.*

*This operation is carried out by operator CALC\_CHAR\_CINE.*

## 2.3

*Calculation of K'*

*K' is directly calculated at the assembly time by operator ASSE\_MATRICE provided naturally that one provides in argument a list of loads kinematics.*

*The structure of data MATR\_ASSE\_\* was modified in order to be able to store K' when that is necessary.*

## 2.4

*Calculation of f'*

*Operator FACT\_LDLT not being modified, the concept of the produced matr\_asse\_\* type, contains factorized of K' and the unchanged matrix K.*

LG

*The calculation of f' is carried out at the time of the resolution: it is necessary to provide to operator RESO\_LDLT in*

0

*argument the kinematic vector corresponding to u0 via key word CHAM\_CINE.*

uL

*This operator calculates then*

U

*f' before solving fact (K')*

*G = f'.*

*The following table has three columns. The name of the sizes appears in the left-hand column (classified by alphabetical order).*

*Each size is separated from following by a white line.*

*On the first line of a size, one finds the type of this size (reality: R, complex: C,...)*

*One lists then the names of the components of this size (column 2) and one makes a small comment on each one of them.*

***Constraints, efforts, forces and deformations***

***Summary:***

*This document defines the sizes characterizing the constraints, the forces and the deformations inside one structure in a calculation by finite elements in displacement and how that is translated in Code\_Aster. The expression of these sizes is given for the finite elements of mechanics: continuous medium 2D or 3D, hulls and beams.*

## *1 Statics*

### *1.1 Constraints*

*The postulate of Cauchy is that the efforts of contacts exerted in a point by part of a medium continuous on another depends only on the normal on the surface in this point delimiting the parts.*

*In accordance with this postulate, one calls vector forced, for the nonmicropolar mediums,  $F(N)$  the vector which characterizes the forces of contact exerted through an element of surface  $dS$  of normal  $N$  on part of a continuous medium [bib1].*

*It is shown [bib3], then, that the dependence in a fixed point of  $F$  compared to normal  $N$  is linear and that there is a tensor which one calls tensor of the constraints such as:*

$$F(N) = N$$

*The unit of the constraints is  $N.m^2 Pa$ .*

*For the whole of the structure “the state of constraint” is characterized by a field of tensor of constraints which one more simply indicates by stress field.*

## **1.2 Effort**

*With regard to the structures of beams or hulls, contrary to the case of the continuous medium, it is necessary to note that:*

- only normal directions  $N$  of the cuts according to tangent space with the variety are possible,*
- the characteristic sizes are obtained by integration in the section or the thickness sizes defined for the continuous mediums.*

*: 3/16*

### **1.2.1 Case of the beams**

*One calls effort, the end cells ( $F$ ,  $M$ ) out of  $P$ , geometrical centre of inertia of the section right-hand side, of the torque resulting from the forces of contact exerted on the section [bib2].*

*With the preceding notations:*

*$F$*

*=  $F$  ( $\cdot$ )  $ds$*

*(NR)*

$$M = \int PM F (\cdot) ds (NR)$$

$m$

$p$

.

$P$

*For the beams whose cross-section is not regarded as rigid these end cells are not sufficient: for example, for the beams taking of account the warping of sections one is brought to consider an additional size of effort due to warping (bimoment).*

*Multifibre beams (with local behavior 1D, connecting constraints to deformations, in one certain number of points of the section) and the pipes (local behavior in plane constraints) are comparable to elements of traditional beams with regard to the movement of fibre average and torques of resulting efforts.*

### 1.2.2 Case of the hulls

*Either, a point  $P$  of a surface medium  $S$  thickness  $H$ , or  $dl$  an element length on  $S$ , or  $N$  normal directing the hull in this point.*

*Maybe, end cells in this point ( $F, M$ ) of a torque resulting from the actions of contact exerted through an element of surface  $dS = H dl$  of tangent normal to  $S$  on part of  $S$ .*

*With the preceding notations:*

$$+h/2$$

$$F (P)$$

$$= \int F (\cdot) dh$$

$$(NR)$$

$- h/2$

$+h/2$

$$M (P) = \int PM F (\cdot) dh (NR.)$$

$m$

$- h/2$

U2.01.05-B Page

: 4/16

*N**dl**H**It is clear that  $M$  is in the tangent plan with  $S$  in  $P$ .**Either,  $NR(P)$  the projection of  $F(P)$  on the tangent level with  $S$  out of  $P$ , and or,  $T(P)$  its component normal in this tangent plan.**In the same way that for the continuous mediums, one shows that there are two symmetrical tensors  $NR$  and  $M$ , and a vector  $Q$ , defined in the tangent plan with  $S$ , such as:*

$$\mathbf{F} = NR$$

$$T = Q.$$

$$\mathbf{M} = N M$$

*( $NR, M, Q$ ) the efforts at the point  $P$  are called:*

- *the tensor  $NR$  characterizes the membrane efforts,*
- *the tensor  $M$ , bending moments,*
- *the vector  $Q$ , efforts sharp.*

**Note:**

- *It does not have there universal conventions on the denomination and the signs of these tensors.*

*In particular, the tensor of the bending moments is taken with a sign reverses in the teaching of the ENPC and in practice of the French engineers of the civil engineering. Our convention is used in the great codes of finite elements (ANSYS) and makes it possible to have it even sign for a beam and a plate such as =.*

*· For the curvilinear or surface material structures with nonlinear behavior, it is necessary to relocate the stress field in the section or the thickness, but them equilibrium equations always relate to the fields of effort. It is not necessary of to go down again to the constraints to define L " state of stress ".*

### ***Bonds with the stress field***

*Under these conditions is a reference mark whose third component is carried by N, one has (, =1 or 2)*

:

*+h/2*

*NR*

*= NR =*

*dh*

*- H/2*

*+h/2*

*M*

$$= M = x^3$$

$$dh$$

$$- H/2$$

$$+ h/2$$

$$Q$$

$$=$$

$$dh$$

$$3$$

$$- H/2$$

### **1.3 Forces nodal**

*One calls equivalent nodal force or more simply nodal force, a vector  $F$  which is it representative of a linear form  $W$  (generally dependent on an energy) acting on fields of displacement  $U(X)$  discretized by finite elements.*

*The fields of displacements  $U(X)$  are expressed starting from its nodal values which form a vector  $Q$  and of the functions of form  $I(X)$  by:*

$$($$

$$U(X) = Q I(X)$$

$$I$$

$$)$$

$$I$$

*Under these conditions:*

$$W(U) = Q F$$

$$I$$

$$I$$

$$I$$

#### **Note:**

- The concept of node here is very general and wants to say, in fact, carrying degree of freedom (that it maybe of Lagrange or Hermit besides).*
- The concept of displacement is also very general and includes the concept of displacement generalized including/understanding translations and rotations.*

### **1.4 Representation of the fields**

*There are several ways of representing the fields in a modeling by finite elements:*

*· for the continuous-current fields on all the field, one uses the values with the nodes, (CHAM\_NO of Aster)*

*(X) = (X*

*I*

*I*

*)*

*I*

*one speaks then about constraints to the nodes or efforts with the nodes,*

**Note:**

*The effort or stress fields are generally discontinuous, if one them represent way continuous it is only at ends of visualization.*

*· for the discontinuous fields between the elements E, one uses the values in some then points characteristic of the element (points of Gauss or nodes).*

*One speaks then about constraints to the nodes by elements or efforts with the nodes by elements, or, of constraints at the points of Gauss or efforts to the nodes.*

*Instruction manual*

*U2.01 booklet: General concepts*

*HT-66/03/002/A*

*Author (S):*

**J.M. PROIX, Key P. MIALON**

*:*

*U2.01.05-B Page*

*: 6/16*

*In practice, for the discontinuous fields one uses:*

*· representations with the nodes at ends of direct uses of the results (impression or*

*postprocessing of visualization),*

*· at the points of Gauss (or in what holds place of it), to continue calculations requiring it true “state of stress” in the element: geometrical rigidity, nodal force, calculations not linear.*

## **1.5**

### **Sizes associated in Aster**

#### **1.5.1 SIGM\_R**

*Size SIGM\_R represents the “state of stress” of the structure, therefore it must have, with minimum, components:*

*· of the stress fields of the continuous mediums (in total reference mark):*

**SIXX SIYY SIZZ SIXY SIXZ SIYZ**

*· of the fields of efforts of beam (in local reference mark with the beam):*

**NR**

**VY**

**VZ**

**MT**

**MFY**

**MFZ**

*· for the beams with warping, it is necessary to add bimoment (necessarily in reference mark room with fibre):*

**BX**

*· of the fields of efforts of hull (necessarily in local reference mark on the surface):*

**NXX**

**NY Y**

**NXY**

**MX X**

**MY Y**

**MX Y**

**QX**

**QY**

*Moreover, it is sometimes convenient to be able to directly exploit the fields of efforts of beam in the total reference mark:*

***FX***  
***FY***  
***FZ***  
***MX***  
***MY***  
***MZ***

*It is also interesting to represent the components of a stress field on elements of beams or hulls in the local reference mark. For that, one will use the same ones components that in total reference mark, although confusion is possible. Into the future, one will introduce a concept of reference mark of representation attached to the fields which will overcome the difficulty.*

### ***1.5.2 FORC\_F and FORC\_R***

*These sizes represent the forces applied to the structure to an interface.  
For:*

- a continuous medium it is thus a vector of force,*
- a beam, a torque of forces,*
- a hull, a torque of forces.*

*This size must thus have the following components:*

- for a continuous medium:*

***FX***  
***FY***  
***FZ***

- more for the beams and the hulls:*

***MX***  
***MY***  
***MZ***

***Instruction manual***

:

U2.01.05-B Page

: 7/16

### **1.5.3 DEPLA\_R**

*Since in Aster,*

- *a field can be attached only to only one size,*
- *that methods finite elements mixed (mixing unknown of displacement type and unknown factors of nodal the forces type) are not excluded,*
- *that the dualisation of the boundary conditions results in having for unknown a vector comprising variables of Lagrange which are nodal forces with the direction where one it specified higher,*
- *that it is necessary to be able to carry out any type of linear combination on nodal forces,*
- *that the classification of unknown must be the same one as that of the second members,*

*the nodal forces (dual within the meaning of energy  $W$  of nodal displacements) have necessarily them same components as displacements with knowing:*

**DX**

**DY**

**DZ**

**DRX**

**DRY**

**DRZ**

*more, for the beams with warping, bimoment: GRX.*

### **1.6**

**Options of calculation**

## ***1.6.1 Calculation of the “state of stress”***

### ***1.6.1.1 Prefixes***

***:***  
***SIEF\_ELGA***

***They are the options which calculate the field representative of the “state of stress” and allow to continue calculations (geometrical rigidity, nodal forces, etc.) in points of Gauss or it who holds place of it. The prefix of these options is SIEF, because according to the elements, they calculate constraints or of the efforts.***

#### ***Option of calculation***

: 9/16

**Note:**

1) *In this case, confusion is possible between the components in local reference mark and those in total reference mark which bears the same name. In the long term, one will introduce into Aster, a concept of reference mark related to the fields of sizes. This notion will be exploited for the writing of the fields with universal format IDEAS, and the impression on listing.*

2) *6 components delivered in the local reference marks by the beams and the hulls contain possibly null terms according to the models used. For the models most standard:*

-  
*three null terms for the beams,*

-  
*two null terms for the hulls.*

*Thus, the stress field will be complete for IDEAS, and, especially, it could be enriched each time modeling requires it (beam with shearing, hull with*

*pinching, etc...)*

### 2.1.2 Case of the beams

In the theories of traditional beams, each point P of the beam represents a section right-hand side. They are thus, the end cells of the torque (T (S), (S)) of displacement of presumed rigid cross-section which characterizes the displacement of the point P to the curvilinear X-coordinate (S).

T is the translation of the centre of inertia of the section, (S) the vector rotation of the section in it not.

The application of the theorem of virtual work (cf [bib2]) naturally resulted in defining as deformation the torque (,) derived from (T (S), (S)) compared to the curvilinear X-coordinate S:

$$D = T + ds$$

$$D = ds$$

$$P(S)$$

*Let us pose then:*

$$= L + T$$

$$=$$

$$T + \mathbf{K}$$

*L is the longitudinal deflection,*  
*T is the vector of the deformations of distortion (no one on the assumption of Navier-Bernoulli),*  
*T is the deformation of torsion of the section,*  
*K is the deformation of inflection.*

**Note:**  
*For modelings of beam with taking into account of warping, kinematics is more*

*complicated to describe, but they lead however to concepts close to those presented above.*

### **2.1.3 Case of the hulls**

*We will limit ourselves here to the cases of the plates. Indeed, in the case general of the hulls:*

- space derivations use too complicated mathematical concepts for the framework this document, [R3.07.04],*
- the hulls are very often modelled by elements of assembled plates.*

*In this case, in fact only the material normals are supposed to be rigid. Displacement of these normals is thus represented by the end cells of a torque ( $T$ ).  $T$  is translation of the point located on the average layer, the vector rotation of the normal in this point. It is clear that the normal component of is null (in the case of nonmicropolar mediums). One introduced, the vector  $L$  in the tangent plan defined by:*

$$L = N$$

*where  $N$  is the normal vector directing surface.*

$N$   
 $e_2$   
 $e_1$

***Maybe, decomposition:***

$$T = wn + C$$

*C is tangent displacement,*

*W is the arrow.*

*In the same way that for the beams, the application of the theorem of virtual work (cf [bib2]) conduit to define as deformation the unit formed by the tensors  $E$  and  $K$  and the vector all these sizes being defined in the tangent plan by:*

$$E = 2 (U, + U$$

, )

$I$

$$K =$$

$$2 (L, + L$$

, )

$$= L + W$$

,

***The deformation is thus defined by 7 realities.***

*E are the membrane deformations,*

*K are the opposite of the curves of the deformed average layer,*

*is the vector of deformation of distortion.*

***Note:***

***There still, there is no universal convention and the disparity of conventions is still larger than for the tensors of efforts. The ENPC adopts a convention reverses for tensor  $K$  for obvious geometrical ratios.***

***Bond with the three-dimensional field of deformation***

***Under these conditions, one a:***

$= E + X$

$K$

$3$

$3 =$

$33 = 0.$

***Constraints, efforts, forces and deformations***

***Summary:***

*This document defines the sizes characterizing the constraints, the forces and the deformations inside one structure in a calculation by finite elements in displacement and how that is translated in Code\_Aster. The expression of these sizes is given for the finite elements of mechanics: continuous medium 2D or 3D, hulls and beams.*

*1 Statics*

*1.1 Constraints*

*The postulate of Cauchy is that the efforts of contacts exerted in a point by part of a medium continuous on another depends only on the normal on the surface in this point delimiting the parts.*

*In accordance with this postulate, one calls vector forced, for the nonmicropolar mediums,  $F(N)$  the vector which characterizes the forces of contact exerted through an element of surface  $dS$  of normal  $N$  on part of a continuous medium [bib1].*

*It is shown [bib3], then, that the dependence in a fixed point of  $F$  compared to normal  $N$  is linear and that there is a tensor which one calls tensor of the constraints such as:*

$$F(N) = N$$

*The unit of the constraints is  $N.m^2 Pa$ .*

*For the whole of the structure “the state of constraint” is characterized by a field of tensor of constraints which one more simply indicates by stress field.*

## **1.2 Effort**

*With regard to the structures of beams or hulls, contrary to the case of the continuous medium, it is necessary to note that:*

*· only normal directions  $N$  of the cuts according to tangent space with the variety are possible,*

*· the characteristic sizes are obtained by integration in the section or the thickness sizes defined for the continuous mediums.*

*: 3/16*

### **1.2.1 Case of the discrete ones**

*The discrete ones are finite elements which can not have of a physical size. They are represented by their matrix of stiffness. The efforts are obtained by the multiplication of this matrix by the vector displacement:*

*$F$*

*$D$*

*$= [K]$*

*M*  
*R*

### 1.2.2 Case of the beams

*One calls effort, the end cells ( $F$ ,  $M$ ) out of  $P$ , geometrical centre of inertia of the section right-hand side, of the torque resulting from the forces of contact exerted on the section [bib2].*

*With the preceding notations:*

*F*  
*= F ( ) ds*  
*(NR)*

*M*  
*= PM F*  
*.*  
*P*  
*( ) ds (NR m)*

*P*

*For the beams whose cross-section is not regarded as rigid these end cells are not sufficient: for example, for the beams taking of account the warping of sections one is brought to consider an additional size of effort due to warping (bimoment).*

*Multifibre beams (with local behavior 1D, connecting constraints to deformations, in one certain number of points of the section) and the pipes (local behavior in plane constraints) are comparable to elements of traditional beams with regard to the movement of fibre average and torques of resulting efforts.*

### ***1.2.3 Case of the hulls***

***Either, a point  $P$  of a surface medium  $S$  thickness  $H$ , or  $dl$  an element length on  $S$ , or  $N$  normal directing the hull in this point.***

***Maybe, end cells in this point  $(F, M)$  of a torque resulting from the actions of contact exerted through an element of surface  $dS = H dl$  of tangent normal to  $S$  on part of  $S$ .***

***With the preceding notations:***

***+ $h/2$***

***$F (P)$***

***=***

***$F () dh$***

***(NR)***

***-  $h/2$***

***+ $h/2$***

***$M (P) =$***

***$PM F () dh (NR.)$***

***$m$***

***-  $h/2$***

***$N$***

***$dl$***

***$H$***

***It is clear that  $M$  is in the tangent plan with  $S$  in  $P$ .***

***Either,  $NR (P)$  the projection of  $F (P)$  on the tangent level with  $S$  out of  $P$ , and or,  $T (P)$  its normal component in this tangent plan.***

*In the same way that for the continuous mediums, one shows that there are two symmetrical tensors  $NR$  and  $M$ , and a vector  $Q$ , defined in the tangent plan with  $S$ , such as:*

$$F = NR$$

$$T = Q.$$

$$M = N M$$

*( $NR$ ,  $M$ ,  $Q$ ) the efforts at the point  $P$  are called:*

- *the tensor  $NR$  characterizes the membrane efforts,*
- *the tensor  $M$ , bending moments,*
- *the vector  $Q$ , efforts sharp.*

*Note:*

• *There are no universal conventions on the denomination and the signs of these tensors. In particular, the tensor of the bending moments is taken with a sign reverses in the teaching of the ENPC and in practice of the French engineers of the civil engineering. Our convention is used in the great codes of finite elements (ANSYS) and makes it possible to have it even sign for a beam and a plate such as =.*

• *For the curvilinear or surface material structures with nonlinear behavior, it is necessary to relocate the stress field in the section or the thickness, but them equilibrium equations always relate to the fields of effort. It is not necessary of to go down again to the constraints to define  $L$  " state of stress ".*

***1.3 Forces***

***nodal***

*One calls equivalent nodal force or more simply nodal force, a vector  $F$  which is it representative of a linear form  $W$  (generally dependent on an energy) acting on fields of displacement  $U(X)$  discretized by finite elements.*

*The fields of displacements  $U(X)$  are expressed starting from its nodal values which form a vector  $Q$  and of the functions of form  $I(X)$  by:*

$$\begin{pmatrix} U \\ X \end{pmatrix} = Q \begin{pmatrix} I \\ X \end{pmatrix}$$

*Under these conditions:*

$$W(U) = Q F$$

*Note:*

*The concept of node here is very general and wants to say, in fact, carrying degree of freedom (that it maybe of Lagrange or Hermit besides).*

*The concept of displacement is also very general and includes the concept of displacement generalized including/understanding translations and rotations.*

## *1.4*

### *Representation of the fields*

*There are several ways of representing the fields in a modeling by finite elements:*

*for the continuous-current fields on all the field, one uses the values with the nodes, (CHAM\_NO of Aster)*

$$\begin{pmatrix} U \\ X \end{pmatrix} = \begin{pmatrix} I \\ X \end{pmatrix}$$

*one speaks then about constraints to the nodes or efforts with the nodes,*

*Note:*

*The effort or stress fields are generally discontinuous, if one them represent way continuous it is only at ends of visualization.*

*for the discontinuous fields between the elements E, one uses the values in some then points characteristic of the element (points of Gauss or nodes).*

*One speaks then about constraints to the nodes by elements or efforts with the nodes by elements, or, of constraints at the points of Gauss or efforts to the nodes.*

*Instruction manual*

*U2.01 booklet: General concepts*

*Author (S):*

*J.M. PROIX, Key P. MIALON*

*:*

*U2.01.05-C Page*

*: 6/16*

*In practice, for the discontinuous fields one uses:*

*representations with the nodes at ends of direct uses of the results (impression or postprocessing of visualization),*

*at the points of Gauss (or in what holds place of it), to continue calculations requiring it true “state of stress” in the element: geometrical rigidity, nodal force, calculations not linear.*

*1.5*

*Sizes associated in Aster*

*1.5.1 SIGM\_R*

*Size SIGM\_R represents the “state of stress” of the structure, therefore it must have, with*

***minimum, components:***

.

***stress fields of the continuous mediums (in total reference mark):***

***SIXX SIYY SIZZ SIXY SIXZ SIYZ***

.

***fields of efforts of beam and discrete (in local reference mark with the beam, discrete):***

***NR***

***VY***

***VZ***

***MT***

***MFY***

***MFZ***

.

***for the beams with warping, it is necessary to add bimoment (necessarily in reference mark room with fibre):***

***BX***

.

***fields of efforts of hull (necessarily in local reference mark on the surface):***

***NXX***

***NYY***

***NXY***

***MXX***

***MYY***

***MXY***

***QX***

***QY***

***Moreover, it is sometimes convenient to be able to directly exploit the fields of efforts of beam and of discrete in the total reference mark:***

***FX***

***FY***

***FZ***

***MX***

***MY***

***MZ***

*It is also interesting to represent the components of a stress field on elements of beams or hulls in the local reference mark. For that, one will use the same ones components that in total reference mark, although confusion is possible. Into the future, one will introduce a concept of reference mark of representation attached to the fields which will overcome the difficulty.*

### **1.5.2 FORC\_F and FORC\_R**

*These sizes represent the forces applied to the structure to an interface.  
For:*

- a continuous medium it is thus a vector of force,*
- a beam, a torque of forces,*
- a hull, a torque of forces.*

*This size must thus have the following components:*

- for a continuous medium:*

***FX  
FY  
FZ***

- more for the beams and the hulls:*

***MX  
MY  
MZ***

### **1.5.3 DEPL\_R**

**Since in Aster,**

**.**

**a field can be attached only to only one size,**

**.**

**that methods finite elements mixed (mixing unknown of displacement type and unknown factors of nodal the forces type) are not excluded,**

**.**

**that the dualisation of the boundary conditions results in having for unknown a vector comprising variables of Lagrange which are nodal forces with the direction where one it specified higher,**

**.**

**that it is necessary to be able to carry out any type of linear combination on nodal forces,**

**.**

**that the classification of the unknown factors must be the same one as that of the second members,**

**the nodal forces (dual within the meaning of energy  $W$  of nodal displacements) have necessarily them same components as displacements with knowing:**

**DX**

**DY**

**DZ**

**DRX**

**DRY**

**DRZ**

**more, for the beams with warping, bimoment: GRX.**

## **1.6**

**Options of calculation**

### **1.6.1 Calculation of the “state of stress”**

### **1.6.1.1 Prefixes**

**:**  
**SIEF\_ELGA**

*They are the options which calculate the field representative of the “state of stress” and allow to continue calculations (geometrical rigidity, nodal forces, etc.) in points of Gauss or it who holds place of it. The prefix of these options is SIEF, because according to the elements, they calculate constraints or of the efforts.*

$$U)_{ij} = \frac{(iu J + uj I)}{2}$$

One can want to calculate the “mechanical” deformation, i.e. by cutting off dilations thermics (options EPME\_ELGA\_DEPL and EPME\_ELNO\_DEPL):

$$m_{ij}(U) = \frac{(iu J + uji)}{2}$$

In the case of great displacements, the deformations of Green-Lagrange are (options EPSG\_ELGA\_DEPL and EPSG\_ELNO\_DEPL):

$$E(U) = \frac{(U + U + U U)_{ij}}{2}$$

To which have can want to cut off the thermal deformations (options EPMG\_ELGA\_DEPL and EPMG\_ELNO\_DEPL):

$$E_m(U) = \frac{(U + u + u U)_{ij}}{2}$$

### 2.1.2 Case of the beams

*In the theories of traditional beams, each point  $P$  of the beam represents a section right-hand side. They are thus, the end cells of the torque  $(T(S), (S))$  of displacement of presumed rigid cross-section which characterizes the displacement of the point  $P$  to the curvilinear  $X$ -coordinate  $(S)$ .*

*$T$  is the translation of the centre of inertia of the section,  $(S)$  the vector rotation of the section in it not.*

*The application of the theorem of virtual work (cf [bib2]) naturally resulted in defining as deformation the torque  $(,)$  derived from  $(T(S), (S))$  compared to the curvilinear  $X$ -coordinate  $S$ :*

$$D = T + ds$$

$$D = ds$$

$$P(S)$$

***K***

*L is the longitudinal deflection,*

*T is the vector of the deformations of distortion (no one on the assumption of Navier-Bernoulli),*

*T is the deformation of torsion of the section,*

***K*** *is the deformation of inflection.*

**Note:**

*For modelings of beam with taking into account of warping, kinematics is more complicated to describe, but they lead however to concepts close to those presented above.*

### **2.1.3 Case of the hulls**

***We will limit ourselves here to the cases of the plates. Indeed, in the case general of the hulls:***

.

***space derivations use too complicated mathematical concepts for the framework this document, [R3.07.04],***

*the hulls are very often modelled by elements of assembled plates.*

*In this case, in fact only the material normals are supposed to be rigid. Displacement of these normals is thus represented by the end cells of a torque ( $T$ ).  $T$  is translation of the point located on the average layer, the vector rotation of the normal in this point. It is clear that the normal component of is null (in the case of nonmicropolar mediums). One introduced, the vector  $L$  in the tangent plan defined by:*

$$L = N$$

*where  $N$  is the normal vector directing surface.*

$N$   
 $e_2$   
 $e_1$

**Analytical definition of a stress field  
and of a field of internal variables initial**

**Summary:**

*It is explained how to manufacture two of the fields constituting the initial state of a non-linear calculation*

*(STAT\_NON\_LINE): the stress field and the field of internal variables.*

- the components of the stress field must have an “analytical” form (for example: state of a ground subjected to the “weight of the grounds”),*
- the components of the field of variables intern are nonnull constants.*

*In both cases, the solution consists in connecting a certain number of orders CREA\_CHAMP.*

*For the stress field, the difficulty consists in evaluating the “analytical formulas” (OPERATION=' EVAL').*

*For the field of internal variables, the difficulty comes owing to the fact that the size associated with the internal variables*

*(VARI\_R) has a number a priori unspecified of components: “V1”, “V2”,...*

*The solutions suggested are implemented in test ZZZZ130A.*

*1*

*Definition of the analytical stress field*

*It is supposed that the model contains finite elements of continuous medium (MODELISATION=' 3D').*

*It is wanted that in each point of Gauss, the components of the constraints have the expressions following:*

$$SIZZ = RHO * G * Z$$

$$SIXX = SIYY = KP * SIZZ$$

where:

**RHO:** density

**G:** acceleration of gravity

**Z:** 3<sup>ème</sup> coordinated of space

**KP:** coefficient of “pushed” of the grounds

The solution suggested consists with:

- 1) to define three functions “formulas” corresponding to SIXX, SIYY and SIZZ,
- 2) to constitute a field whose components are the preceding functions,
- 3) to evaluate the formulas of the field by providing him the field of geometry necessary to their evaluation.

### 1.1

Stage 1: to define the formulas

$$RHO=1000.$$

$$G=10.$$

$$KP=3.$$

$$SIZZ = FORMULA (REEL= '''' (REAL: Z) = RHO * G * Z '''' )$$

$$SIXX = FORMULA (REEL= '''' (REAL: Z) = KP * SIZZ (Z) '''' )$$

$$SIYY = FORMULA (REEL= '''' (REAL: Z) = KP * SIZZ (Z) '''' )$$

### 1.2

Stage 2: to create the field of formulas SIG1

$$SIG1=CREA\_CHAMP (OPERATION=' AFFE', TYPE\_CHAM=' ELGA\_NEUT\_F',$$

$$MODELE=MO, PROL\_ZERO=' OUI',$$

$$AFFE=_F (ALL = “YES”, NOM\_CMP = (“X1”, “X2”, “X3”),,$$

$$VALE\_F = (SIXX, SIYY, SIZZ,))$$

### Remarks

- the field SIG1 which one creates is a cham\_elem at the points of Gauss (ELGA),
- the only fields being able to have components of the type “functions” are the fields of size NEUT\_F. It will thus have to be remembered that the CMP “X1” of SIG1 is actually “SIXX”, etc...,
- key word PROL\_ZERO=' OUI' is obligatory bus for all the types of element, them cham\_elem\_NEUT\_R currently has 6 components: “X1”, “X2”,..., “X6”. It is necessary thus to agree “to prolong” by zero the field out of the 3 nonaffected components.

*prolongation by “zero” for a field whose components are texts (names of functions) consists in assigning the chain ““to each component absent from the field. Attention thus, it is not a question of a null function. One can note it while using INFO=2 to print field SIG1.*

*:*

*U2.01.09-A Page*

*: 3/6*

*1.3*

*Stage 3: to evaluate the formulas of field SIG1*

*Field SIG1 is a field known at the points of Gauss of the elements of the model. In each point, one will want to evaluate functions SIXX, SIYY and SIZZ. For that, it is necessary to have the values of all variables appearing in functions (here Z). These variables must be known on same points as the field of functions. It is thus necessary to have a field containing the geometry of points of Gauss (cham\_elem\_GEOM\_R/ELGA).*

*This field of geometry of the points of Gauss (CHXG) is obtained starting from grid (MA) by the 2 following orders:*

*CHXN=CREA\_CHAMP (OPERATION=' EXTR', TYPE\_CHAM=' NOEU\_GEOM\_R',  
NOM\_CHAM=' GEOMETRIE', MAILLAGE=MA)*

*CHXG=CREA\_CHAMP (OPERATION=' DISC', TYPE\_CHAM=' ELGA\_GEOM\_R',  
MODELE=MO, CHAM\_GD=CHXN)*

*The first order extracts the field from geometry (with the nodes) of the grid. The second transform the field of geometry to the nodes into a field of geometry at the points of Gauss in*

*using the functions of form of the finite elements of the model.*

*One can then evaluate the functions thanks to operator CREA\_CHAMP/OPERATION=' EVAL':*

*SIG2=CREA\_CHAMP (OPERATION=' EVAL', TYPE\_CHAM=' ELGA\_NEUT\_R',  
MODELE=MO, CHAM\_F=SIG1, CHAM\_PARA= (CHXG,))*

*Field (SIG2) obtained by evaluation of a field of size NEUT\_F is a field of  
size NEUT\_R whose components have the same names as the components of NEUT\_F:  
"X1", "X2",..., "X6".*

**Caution:**

*The components "X4", "X5", "X6" are indefinite (actually they contain reality it  
larger possible), because they correspond to a non-existent function.*

*It still remains to change the size of field SIG2 (NEUT\_R - > SIEF\_R) to finish  
manufacture of our analytical stress field:*

*SIGINI=CREA\_CHAMP (OPERATION=' ASSE', TYPE\_CHAM=' ELGA\_SIEF\_R',  
MODELE=MO, PROL\_ZERO=' OUI',  
ASSE=\_F (ALL = "YES", CHAM\_GD = SIG2,  
NOM\_CMP = ("X1", "X2", "X3"),,  
NOM\_CMP\_RESU = ("SIXX", "SIYY", "SIZZ",)))*

**Note:**

*· only the components "X1", "X2" and "X3" of field SIG2 are recopied in this  
operation to give components "SIXX", "SIYY", "SIZZ" of field SIGINI.*

*This stress field must also contain the components related to  
shearings ("SIXY", "SIYZ", "SIXZ"). To obtain them (with a zero value), it is necessary  
to use the prolongation by zero (PROL\_ZERO=' OUI'),*

*· handling made to obtain the null components of shearing, would have been  
simpler if there were explicitly affected on these 3 components a null function.*

*One would not have had "to play" with the prolongations. But one would have profited from  
coincidence which sizes SIEF\_R and NEUT\_R have all the two 6 components  
for cham\_elem (ELGA) on the elements of the model.*

***2***

***Definition of the field of variables intern not no one***

***2.1 Problem***

***One wants to create a field of initial internal variables for order STAT\_NON\_LINE. This field does not have to be null everywhere. More precisely, one wants:***

***STAT\_NON\_LINE:***

***COMP\_INCR= (\_F (GROUP\_MA=' MASSIF', RELATION = "CJS"),***

***\_F (GROUP\_MA=' BETON', RELATION = "ENDO\_LOCAL"),),***

***for the relation of behavior "CJS" (16 variables intern), one wants to affect:***

***V1 = 1.0 and V9 = 9.0***

***for the relation of behavior "ENDO\_LOCAL" (2 variables intern), one wants to affect:***

***V2 = 2.0***

***2.2 1st***

***method***

***The operator to be used is CREA\_CHAMP/OPERATION=' AFFE'. He makes it possible to affect (by mesh or***

***GROUP\_MA) the values which one wishes. The difficulty comes owing to the fact that the size associated with***

***internal variables (VARI\_R) is different from the different one: one does not know a priori which are its***

***components. Moreover the name of its components translates this ignorance: "V1", "V2",...***

***According to the behavior which the user in STAT\_NON\_LINE will choose, the number of variables interns changes. In our example, behavior "CJS" requires 16 variables whereas***

***"ENDO\_LOCAL" uses only 2 of them.***

***The operation of assignment is thus done in two stages: one creates initially a CHART of NEUT\_R***

**(VAIN1)**

**with ALL the components wanted including the null components:**

```
VAIN1=CREA_CHAMP (OPERATION=' AFFE', TYPE_CHAM=' CART_NEUT_R',  
MODELE=MO,  
AFFE= (  
_F (GROUP_MA= "CONCRETE", NOM_CMP= ("X1", "X2"), VALE = (0. , 2. ,)),  
_F (GROUP_MA= "MASSIVE",  
NOM_CMP= ("X1", "X2", "X3", "X4", "X5", "X6", "X7", "X8", "X9", "X10",  
"X11", "X12", "X13", "X14", "X15", "X16"),  
VALE = (1. , 0. , 0. , 0. , 0. , 0. , 0. , 0. , 9. , 0. , 0. , 0. , 0. , 0. , 0. , 0. ,)),  
)  
)
```

**One transforms then carte\_NEUT\_R into cham\_elem\_VARI\_R (VAIN11):**

```
VAIN11=CREA_CHAMP (OPERATION=' ASSE', TYPE_CHAM=' ELGA_VARI_R',  
MODELE=MO,  
ASSE= (  
_F (CHAM_GD = VAIN1, GROUP_MA= "CONCRETE",  
NOM_CMP= ("X1", "X2"),  
NOM_CMP_RESU= ("V1", "V2"),),  
_F (CHAM_GD = VAIN1, "MASSIVE" GROUP_MA=  
NOM_CMP= ("X1", "X2", "X3", "X4", "X5", "X6", "X7",  
"X8", "X9", "X10", "X11", "X12", "X13",  
"X14", "X15", "X16"),  
NOM_CMP_RESU= ("V1", "V2", "V3", "V4", "V5", "V6",  
"V7", "V8", "V9", "V10", "V11", "V12",  
"V13", "V14", "V15", "V16"),),  
)  
)  
)
```

:

U2.01.09-A Page

: 5/6

**Note:**

*It is very important for non-linear calculation to come that the field of variables intern is coherent with the behaviors which one will choose. Here, it is necessary that the meshes of the group “CONCRETE” have 2 internal variables (and only 2) and those of the “MASSIVE” group have some 16.*

**Caution:**

*If the model comprises other types of behavior (for which one does not wish to initialize the field with nonnull values), it is also necessary to explicitly affect to them zero values. This disadvantage (of having to know ALL the behaviors used and their number of variables intern) can be raised with the 2nd method below (but it is more complicated).*

### **2.3 2nd method**

*This method (more complicated) makes it possible to affect explicitly only the meshes which have nonnull components.*

*The problem is to obtain a field containing the good number of internal variables for each mesh according to the behavior which will be affected for him in STAT\_NON\_LINE. To solve this problem, one will carry out a non-linear calculation “can” (with the real behaviors). The field of variables interns produced will be then a “model” good of field.*

*One will thus make:*

*1) non-linear calculation can => UBID*

- 2) extraction of the field of variables intern (VBID) result UBID
- 3) assignment of the nonnull values in field VAIN2
- 4) put at zero of VBID + overload of the values of VAIN2 to produce result VAIN22

### 2.3.1 non-linear calculation can

## ***Note of use on the choice of the finite elements***

### ***Summary:***

***The purpose of this document is to give some information on the choice of the finite elements and their modeling associated in the case of studies thermal, thermomechanical or mechanical non-linear. It acts in some kind, to propose with the user a choice a priori, allowing to avoid certain current errors. In cases of particular difficulties, other choices could be made.***

### ***1 Introduction***

***One gives in this document the choices a priori which can be made concerning the finite elements.***

***One***

***was placed in the case of a thermomechanical chaining but the councils are valid on***

***thermal or mechanical not chained calculations (linear or not). A fast justification is given.***

***For more details on the justification of these choices, the user will be able to refer to the documents R of***

***Code\_Aster like with the note H [bib1].***

## 2

### *Choice a priori*

#### 2.1

#### *grid*

*The elements can be indifferently:*

.  
*triangular elements or quadrangles in 2D,*

.  
*tetrahedrons or hexahedrons in 3D.*

*Indeed, contrary to the often spread idea, the elements of the triangle type or tetrahedron give good results, even in plasticity, in condition of course of not using a grid too much coarse. The advantage of this family of elements, it is that it makes it possible to use the software LOBSTER which*

*carry out the adaptation of grids 2D/3D for finite elements of type triangular or tetrahedral by refinement and déraffinement. One can thus obtain the optimum grid according to an indicator of error (cf [R4.10.01], [R4.10.02], [R4.10.03], or the case test TPLL01j [V4.02.01] for one demonstration) by call to order MACR\_ADAP\_MAIL in the command file Aster.*

*On the other hand, it is advised to use:*

.  
*linear elements in thermics for chained calculations and calculations of thermics fast transient. For the other cases, one can also choose quadratic elements,*

.  
*quadratic elements in mechanics.*

*This choice is all the more important when one carries out thermal chained calculations then mechanics. It is then necessary to use two grids for thermics and mechanics. Two strategies are then possible:*

.  
*that is to say independently to net the structure for thermal calculation and mechanical calculation*

.  
*that is to say to carry out a grid with linear elements then to transform it into grid quadratic thanks to the order CREA\_MAILLAGE, key word factor LINE\_QUAD.*

*Whatever the method chosen, one can optimize separately each grid with Homard grace with the thermal and mechanical indicators of error available in Aster (cf case-test forma05b*

[V6.03.120]).

*Note of use on the choice of the finite elements*

*Date*

:

**14/01/03**

*Author (S):*

**Key S. MICHEL-PONNELLE**

:

**U2.01.10-A Page**

**: 3/6**

*Note:*

**1) This remark is addressed to the users of GIBI which were accustomed to netting their structures with quadrangles or cubes and which would wish “to rock” them grid towards triangles or tetrahedrons.**

**In general, to net with tetrahedrons instead of cubes, it is not enough to change in the command file *OPTI DIME 3 ELEM CU20* by *OPTI DIME 3 ELEM TE10*.**

**Indeed, a certain number of orders GIBI are specific to the cubes and do not function to net a structure with tetrahedrons (or do not give it anticipated result). The user can thus be tempted to keep his command file initial and to use at the end of the process of creation of grid order *CHAN TET4* to make the swing.**

**By experiment, we dis advise to the users making this choice for several reasons. First of all, on certain grids, one observed a not-convergence of solution when one used an increasingly fine grid obtained by this method. In more, the change is effective only on volume: the surface meshes are always quadrangles what poses problem to impose the boundary conditions in Aster. Lastly, to net with *TETRA10*, it is necessary to pass by the stage *TETRA4* then to make *QUADRATIC CHAN*. However this change poses problem for *SEG2*.**

**Consequently, with GIBI, it is important to net directly the structure with good elements leaves to have to rewrite its command file. One also announces,**

*that in certain cases, GIBI does not manage to net with tetrahedrons when one asks an important refinement. It is then enough to net coarsely, then to refine it uniform grid of way or not with the software Lobster.*

*2) It is pointed out here that all the sizes of the type forced or deformation are calculated at the points of Gauss, and that any passage to the nodes involves a skew. That is of as much truer when one then seeks to calculate standards; we thus noticed that the tetrahedrons were more sensitive than the hexahedrons to the method of calculation of equivalent constraints for example. It is thus necessary to have an eye even more critical on results calculated with the nodes.*

## **2.2 modeling**

*That it is for the resolution of the thermal or mechanical problems, several modelings are available in Aster. These various modelings can be characterized by the number or the type degrees of freedom, the number of points of integration, treatments particular... According to calculation carried out, some of course are adapted than of others.*

### **2.2.1 In thermics**

*To make thermal calculation in Aster, two types of modelings are accessible ([U3.23.01], [U3.24.01], [R3.06.02], [R3.06.07]):*

*·  
traditional finite elements: modeling 3D, AXIS or PLAN*

*·  
finite elements lumpés or diagonalized  
: modeling 3D\_DIAG, AXIS\_DIAG or  
PLAN\_DIAG*

*We propose like choice by defect:*

*modeling with linear elements  
Instruction manual  
U2.01 booklet: General concepts

**Author (S):**

**Key S. MICHEL-PONNELLE**

**:**

**U2.01.10-A Page**

**: 4/6**

### **Justification**

***In thermics, the step of time  $T$  cannot be unspecified, it must check a condition***

***$T$***

***$min < T$***

***$< T$***

***$max, T$***

***$min$  and  $T$***

***$max$  depending on the properties materials, the size of the elements stop and parameters of temporal integration (cf [R3.06.07]).***

***In the case of fast transitory problems of thermics, one can be brought to use a step of too small time. One can then observe oscillations of the solution and temperatures not physics due to the violation of the principle of the maximum (temperature higher than the initial temperature***

***of a part which one cools). The modeling DIAG, which consists with diagonaliser the matrix of mass, allows to free itself from the condition on  $T$   $min$  and to avoid the associated problems.***

***Let us note however that this diagonalisation is not enough to remove the oscillations with quadratic elements. However, in Aster, a particular treatment is made for the elements 2D: the triangles are automatically cut in linear finite elements which themselves are lumpés.***

### **2.2.2 In mechanics**

***Three types of modelings are available to solve problems of non-linear mechanics using “traditional” laws of behavior (of the elastoplasticity type):***

***.***

***isoparametric traditional finite elements: 3D, D\_PLAN, C\_PLAN, AXIS ([U3.14.01], [U3.13.01]),***

***.***

***under-integrated elements***

***: 3D\_SI, D\_PLAN\_SI, C\_PLAN\_SI, AXIS\_SI ([U3.14.01],***

[U3.13.05]),

.

*elements being based on an quasi-incompressible formulation*

*: 3D\_INCO,*

*D\_PLAN\_INCO, AXIS\_INCO ([U3.14.06], [U3.13.07], [R3.06.08]).*

*We propose like choice a priori to use:*

*quadratic elements*

*With regard to the choice of modeling, it is a function of the type of elements and the need to treat the condition of incompressibility. These considerations are summarized in the table below.*

*normal*

*quasi-incompressible*

*(strong*

*plasticity or >0.45)*

*standard triangles/tetrahedrons*

*INCO*

*quadrilaterals/hexahedrons*

*IF*

*IF or INCO*

*: 5/6*

## ***Justifications and precautions:***

*If the material is quasi-incompressible ( $> 0.45$ ), it is preferable to use the formulation INCO, because the standard formulation in displacement does not give good results.*

*The plastic flow is done with constant volume. This condition of incompressibility can cause difficulties with traditional modeling of knowing a too rigid behavior and especially appearance of oscillations on the level of the constraints. Under-integration allows to improve these problems, because one then checks the condition of incompressibility in less points of Gauss. However, only elements QUAD8 and HEXA20 are really under-integrated, for the other meshes, it is the traditional integration which is preserved. In consequence, when phenomena of oscillations are observed for a grid composed of triangles or tetrahedrons, it is preferable to use formulation INCO. This improve the result clearly but calculations will be longer.*

*In the case general, under-integrated modeling gives of as good results as them traditional finite elements, and this for a faster computing time since one uses less points of Gauss. In the case of thermomechanical calculations, that allows to limit the difficulties at the time of the passage of the thermal deformation of origin to calculation mechanics when refinements of the grids thermics and mechanics differ. However, under-integration can sometimes lead to the appearance of parasitic modes. If at the end of calculation the deformation presents this kind of nonphysical modes of deformation, it is better to make calculation with traditional or quasi-incompressible modeling if levels of plasticity are very important.*

## **3 Implementation Aster**

*One points out here the principal stages of Aster calculation in the case of a calculation in plane deformations, while specifying explicitly where the specifications intervene about which one spoke. For the part mechanics, one wrote in fat what is specific to the case of a thermomechanical calculation.*

## **1 Introduction**

*The elements of hulls and plates are particularly used to model structures thin where the relationship between dimensions (characteristic thickness/length) is much lower than 1/10 (thin hulls) or of the order de 1/10 (thick hulls).*

*These modelings are usable in linear and nonlinear mechanics, under assumption of small deformations and small displacements or many assumptions of great displacements and of great rotations, according to modelings. A mean modeling of hull is also available in transitory linear thermics.*

*Two categories of thin elements of structures are described in this document:*

*The elements of plates, which are plane, therefore the curve of the structure to be represented is not ideally not taken into account and it is necessary to use a great number of elements of way to approach correctly the geometry of the structure (aspect facets).*

*The elements of hulls, which are curved, therefore the geometry of the structure is better approached.*

*Concerning the nomenclature and the reference materials associated with each one of modelings:*

*the plane elements of plates triangle and quadrangle are gathered under modelings, (reference material [R3.07.03]):*

*DKT: net TRIA3 element DKT, mesh QUAD4 elements DKQ (linear geometrical);*

*DST: net TRIA3 DST element, mesh QUAD4 element DSQ (linear geometrical);*

*Q4G: net QUAD4 element Q4G (linear geometrical);*

*the elements of curved hulls resulting from models 3D with a kinematics of hull are gathered under modelings:*

*COQUE\_3D: net TRIA7 and QUAD9, structure 3D with unspecified geometry ([R3.07.04] into linear geometrical, [R3.07.05] into linear geometrical and [R3.03.07] with following pressures);*

*COQUE\_AXIS: net SEG3, hulls with symmetry of revolution around the axis 0Y ([R3.07.02] into linear geometrical);*

*COQUE\_C\_PLAN or COQUE\_D\_PLAN: net SEG3, hulls with invariant geometry it length of axis OZ ([R3.07.02] into linear geometrical).*

*A characteristic: for studies on reinforced concrete structures, elements of plates specific were developed to represent the tablecloths of reinforcement made up of two metal reinforcements with 90° one compared to the other (case more general for the concrete structures armed). They are elements of orthotropic plates DKT to 3 nodes offset compared to the layer means out of concrete. This last is modelled by elements of plates DKT or DST with 3 nodes. One for the tablecloths of reinforcement a modeling defines ROASTS which uses the elements of plates DKT with 3 usual nodes. The reinforced concrete structure is then represented by the superposition of modelings ROASTS and of that used for the concrete (DKT or DST).*

*To represent hulls with symmetry of revolution around an axis (COQUE\_AXIS) or hulls with invariant geometry by translation (COQUE\_C\_PLAN in plane constraints or COQUE\_D\_PLAN in plane deformations), the knowledge of the section of revolution or the trace of surface average is sufficient, as the figure [2.1.2.1 Figure - has] shows it to us. These hulls rest on a linear grid and in a point m of average surface one defines a local reference mark (N, T, ez) by:*

*Om  
T =  
, S; N T = E  
Om  
Z.  
, S*

*When one wishes to model a solid of an unspecified form (not plan), one can use elements of hulls to account for the curve, or many elements of plates. In it last case, the geometry is approximated by a network of facets.*

## **2.1.2 Formulation of the elements plates and hulls**

### **2.1.2.1 Formulation into linear geometrical**

**In this formulation, one supposes that displacements are small, one can thus superimpose initial geometry and deformed geometry. These elements are based on the theory of the plates according to which:**

**.  
the cross-sections which are the sections perpendicular to the surface of reference remain right-hand sides; material points located on a normal at not deformed average surface remain on a line in the deformed configuration. It results from this approach that the fields of displacement vary linearly in the thickness of the plate or of hull. If one indicates by  $U$ ,  $v$  and  $W$  displacements of a point  $Q (X, y, Z)$  according to  $X$ ,  $y$  and  $Z$ , one has as follows:**

**$U (X,$   
 $y Z) U (X, y)$   
 $(X, y)$**

**X**

$$v(X, y) Z = v(X, y) + Z(X, y)$$

$$W(X, y) Z = W(X, y)$$

0

*The associated tensor of deformation is written then:  $(X, y) Z = E(X, y) + (X, y) + Z(X, y)$ .*

*first term  $E$  includes/understands the deformations of membrane (for an element of plate it are the deformations in the plan of the element), the second those of shearing transverse, and third  $Z$  deformations of inflection, associated the tensor of curve. For the thick plates or hulls transverse shearings are taken in account following the formulation suggested by Reissner, Hencky, Bollé, Mindlin. This formulation includes the approach without transverse shearing, where the tensor is null, developed by Kirchhoff for the thin plates or hulls according to which points materials located on a normal  $N$  at not deformed average surface remain on normal on the deformed surface.*

*the transverse constraint is null bus regarded as negligible compared to*

*zz*

*other components of the tensor of the constraints (assumption of the plane constraints).*

*one does not describe the variation thickness nor that of the transverse deformation that one*

*zz*

*can calculate by using the preceding assumption of plane constraints.*

*the taking into account of transverse shearing depends on given factors of correction has priori by energy equivalences with models 3D, so that rigidity in transverse shearing of the model of plate is nearest possible to that defined by the theory of three-dimensional elasticity. For the homogeneous plates, the factor of transverse correction of shearing based on this method is  $k=5/6$ .*

**Note:**

*The determination of the factors of correction rests for Mindlin on equivalences of Eigen frequency associated the mode of vibration by transverse shearing. One obtains then  $K = 2/12$ , value very close to  $5/6$ .*

### **2.1.2.2 Formulation into non-linear geometrical, Buckling of Euler**

*In the formulation into non-linear geometrical, one is in the presence of great displacements and of great rotations, one cannot superimpose the initial geometry and the deformed geometry.*

*The formulation, described in the reference material [R3.07.05], is based on an approach of continuous medium 3D, degenerated by the introduction of the kinematics of hull of the type*

*Hencky-Mindlin-Naghdi in plane constraints in the weak formulation of balance. The measurement of deformations selected is that of Green-Lagrange, vigorously combined with the constraints of Piola-Kirchhoff of second species. The formulation of balance is thus a formulation Lagrangian total. Transverse shearing is treated same manner as in the case linear [R3.07.04].*

*The element retained into non-linear is a voluminal element of hull (COQUE\_3D) of average surface curve as presented at the preceding paragraph, whose meshes supports are QUAD9 and TRIA7.*

*It is possible to apply to these elements of the following pressures, whose formulation is described in the reference document [R3.03.07]. This loading with the characteristic to follow the geometry of the structure during its deformation (for example, the hydrostatic pressure always remains perpendicular with the deformed geometry).*

*Linear buckling also called buckling of Euler, described in the reference material [R3.07.05], is presented in the form of a particular case of the geometrical non-linear problem. It is based on a linear dependence of the fields of displacements, strains and stresses by report/ratio on the level of load.*

*The element retained in linear buckling is the voluminal element of hull (COQUE\_3D) of surface curved average as presented at the preceding paragraph, whose meshes supports are QUAD9 and of the TRIA7.*

### *2.1.3 Comparison enters the elements*

#### *2.1.3.1 differences between the elements plates and hulls*

*The elements of hull are curved elements whereas the elements of plates are plane. variation of metric of the geometry (i.e. its radius of curvature) according to sound thickness is taken into account for the elements of hulls but not for the elements of plates. This variation of metric implies a coupling between the effects of membrane and inflection for nonplane structures which cannot be observed with elements of plate plan for one homogeneous material (see [bib1]).*

*The choice of the functions of form for the discretization of these elements is different bus the elements curved hulls have a more significant number of degrees of freedom. Thus, elements of plates are linear elements out of membrane whereas the elements of hulls are quadratic.*

#### *2.1.3.2 differences between the elements plates*

*One distinguishes the elements with transverse shearing (DST, DSQ and Q4G) from the elements*

*without transverse shearing (DKT and DKQ). Elements DST and DKT have triangular meshes support with 3 nodes ( $3 \times 5 = 15$  ddl) and elements DKQ, DSQ and Q4G of the quadrangular meshes supports to 4 nodes ( $4 \times 5 = 20$  ddl).*

**Important remark:**

*For the elements of plate with 4 nodes (DSQ, DKQ and Q4G), the 4 nodes must be coplanar so that the theory of the plates can be validated. This checking is carried out systematically by Code\_Aster, and the user is alarmed if one elements of the grid does not observe this condition.*

**: 10/50**

*In the case of elements with transverse shearing, to avoid the blocking of the elements in transverse shearing (over-estimate of rigidity for very low thicknesses), a method consist in building fields of constant shearing of substitution on the edges of the element, whose value is the integral of shearing on the edge in question. In Code\_Aster, the elements of plate and hull with transverse shearing use this method in order not to block in transverse shearing. This blocking in shearing comes owing to the fact that elastic energy from shearing is a term proportional to  $H$  ( $H$  being the thickness of the plate or the hull) much more large that the elastic term of energy of inflection which is proportional out of  $H^3$ . When the thickness becomes weak in front of the characteristic length (the  $h/L$  report/ratio is lower than  $1/20$ ), for some functions of form, the minimization of the dominating term out of  $H$  leads to bad representation of the modes of pure inflection, for which the arrow is not calculated any more correctly*

(see [bib1] page 295 with  $h/L=0.01$ ).

*Element Q4G is a quadrilateral element with four nodes without blocking in transverse shearing, with bilinear functions of form in  $X$  and to represent  $W$ ,  $X$  and  $Y$ . there It is the same for elements DST and DSQ. The difference between DSQ and Q4G (DST modeling, [bib1]) comes owing to the fact that*

*one uses for the latter of the quadratic functions of form to discretize on each edge rotation  $S$  in the  $sz$  plan where  $S$  is the co-ordinate along the sides. Rotation  $N$  in the  $nz$  plan where  $N$  is the normal at the side directed towards the outside of the element remains discretized with functions of form bilinear (see it [2.1.3.2 Figure - has]).*

*Appear 2.1.3.2 - has: Element of plate with transverse shearing*

### *2.1.3.3 differences between the elements hulls*

*One distinguishes the linear elements of hulls COQUE\_C\_PLAN, COQUE\_D\_PLAN and axisymmetric COQUE\_AXIS of the elements of COQUE\_3D.*

*The first are used to model invariant structures according to axis OZ or of revolution of axis OY and seconds in all the other cases. In the case of invariant hulls according to direction Z, one distinguishes the free hulls in Z (forced plane COQUE\_C\_PLAN) from the hulls blocked in Z (plane deformations COQUE\_D\_PLAN). For these elements of hulls, meshes supports are linear with 3 nodes. The number of degrees of freedom of these elements is 9.*

## **Author (S):**

**A. ASSIRE, P. MASSIN, F. LEBOUVIER Key**

**:**

**U2.02.01-A Page**

**: 11/50**

**The unspecified elements of hulls COQUE\_3D have triangular meshes support with 7 nodes or quadrangular with 9 nodes:**

**.**

**In the case of triangular meshes, the number of degrees of freedom for the translations is 6 (the unknown factors are displacements with the nodes tops and on the mediums on the sides of triangle) and that of rotations are the 7 (unknown factors are 3 rotations at the preceding points and in the center of the triangle). The number of degrees of freedom total of the element is thus of  $N_{dof} = 3 \times 6 + 3 \times 7 = 39$ .**

**.**

**In the case of quadrangular meshes with 9 nodes, the number of degrees of freedom for translations is the 8 (unknown factors are displacements with the nodes tops and on mediums on the sides of the quadrangle) and that of rotations is the 9 (unknown factors are the 3 rotations at the preceding points and the center of the quadrangle). The number of degrees of freedom total of the element is thus of  $N_{dof} = 3 \times 8 + 3 \times 9 = 51$ . These elements thus have about two time more degrees of freedom than the elements of plate of corresponding family DKT. Their cost in time, with an equal number, in a calculation will be thus more important.**

**The elements of COQUE\_3D automatically take into account the correction of metric between surface average and the surfaces upper and lower. For the linear elements, this correction must be activated by the user (see the paragraph [14](#)). The correction of metric brings one contribution in  $h/L$  to the constraint and  $(h/L)^2$  in displacement (see [V7.90.03]). For the plates this correction is without object.**

**For the elements of hulls the coefficient of correction of shearing  $K$  in isotropic behavior can be modified by the user. This coefficient of correction of shearing is given in**

***AFFE\_CARA\_ELEM under key word A\_CIS. By defect, if the user does not specify anything in AFFE\_CARA\_ELEM that amounts using the theory with shearing of REISSNER; the coefficient of shearing is then put at  $k=5/6$ . If the coefficient of shearing  $K$  is worth 1 one places within the framework***

***theory of HENCKY-MINDLIN\_NAGHDI and if it becomes very large ( $10^6 h/L$ ) one brings closer the theory of LOVE\_KIRCHHOFF.***

***In practice it is advised not to change this coefficient. Indeed, these elements provide one physically correct solution, that the hull is thick or thin, with the coefficient  $K = 5/6$ .***

*The easily affected characteristics on the elements of plate or hull are:*

·  
*the constant THICK thickness on each mesh, since the grid represents only it average layer.*

·  
*the coefficient of correction of transverse shearing A\_CIS for the curved hulls isotropic.*

.  
*the taking into account of the correction of metric **MODI\_METRIQUE** enters average surface and surfaces upper and lower (effective only for the **COQUE\_C\_PLAN**, **COQUE\_D\_PLAN**, **COQUE\_AXIS**).*

.  
*a direction of reference **D** defined by two nautical angles given in the total reference mark, by key word **ANGL\_REP**. The projection of this direction of reference on the tangent level to the hull fixes **X1**, the first direction of the local reference mark. The normal in the tangent plan in fixed one*

*second and the vector product of the two associated vectors makes it possible to define the local trihedron.*

*necessary to the supply of the characteristics nonisotropic material and for the analysis of the efforts generalized, of the state of stress or the generalized and three-dimensional deformations. The user will have to take care that the selected reference axis is not found parallel with normal of certain meshes of the grid. By defect, this direction of reference is axis **X** total reference mark of definition of the grid.*

.  
*a functionality of **DEFI\_GROUP** makes it possible to create a group of meshes automatically of which it normal is included/understood in a given solid angle, of axis direction of reference. This order can be used in preprocessing to affect data material not isotropic or in postprocessing after a calculation of hull.*

*tangent*

**X**

*The total xy plan is not parallel in the tangent plan*

**Appear 2.2.2-a: Total reference mark and tangent plan**

*For modeling ROASTS, the following geometrical data are necessary to model them tablecloths of reinforcements (see [3]):*

.  
*offsetting (constant for all the nodes of the mesh) OFFSETTING of each one they compared to the mesh support. This distance is measured on the normal of the mesh support which, in practice, is superposable with that of the concrete.*

.  
*direction of reference D defined previously by ANGL\_REP.*

.  
*direction of the reinforcements compared to the X1 vector of the tangent plan. One of the directions ANGL\_L is enough because the grid consists of orthogonal reinforcements between them.*

.  
*percentages of section of reinforcement in direction 1 POUR\_CENT\_L and direction 2 POUR\_CENT\_T which is orthogonal for him.*

.  
*the sum of the sections of reinforcements per unit of width in direction 1 SECTION\_L.*

**Important remark:**

*Orientation of the elements of plates and hulls*

*The direction of the normals to each element is a recurring problem concerning the use of this type of element, for example when loadings of the pressure type are applied, or to define a offsetting or a local reference mark.*

*By defect for the surface elements the orientation is given by the vector product  $12^{\wedge}13$  for a triangle numbered 123 (DKT,...) or 1234567 (COQUE\_3D) and  $12^{\wedge}14$  for a numbered quadrangle 1234 (DKQ,...) or 123456789 (COQUE\_3D). For linear hulls  $N$  is given by the formula of [2.1.1.1](#) paragraph [with](#)  $T$  directed in the direction of course of the mesh on the level of the grid.*

*Generally, these data are accessible while looking in the file from grid, which is not very practical for the user. Moreover it is necessary that it checks the coherence of its grid and to ensure itself*

*that all the meshes have the same orientation well.*

*The user can automatically modify the orientation of the elements of the grid by imposing one direction of normal, for a grid or part of using grid of modelings of hull and whatever the type of modeling. The reorientation of the elements is done by the means of operator `ORIE_NORM_COQU` of order `MODI_MAILLAGE` [U4.12.05]. The principle is it according to: one defines under `ORIE_NORM_COQU` a direction by the means of a vector and a node belonging to the group of meshes to be reorientated. If the introduced vector is not in the plan of the mesh selected by `MODI_MAILLAGE`, one automatically deduces a direction from it from normal obtained like the vector less given its projection in the field of the mesh. All meshes of the group related with those initially selected will then have the same orientation of normal automatically. In addition an automatic checking of the same orientation of the meshes*

*related is carried out by the means of operator VERI\_NORM of order AFFE\_CHAR\_MECA [U4.25.01].*

### **2.2.3 Materials**

### ***Appear 2.2.3-a: Reference marks used for the definition of material***

*The following example is extracted from case-test SSLS117B and illustrates the syntax of DEFI\_COQU\_MULT:*

```
MU2=DEFI_COQU_MULT (COUCHE=_F (EPAIS=0.2,  
MATER=MAT1B,  
ORIENTATION=0.0,));
```

*In this example, one defines a multi-layer composite thickness 0.2, the material being defines by MAT1B, and the angle of the 1st direction of orthotropism (longitudinal direction or direction of fibres) being null. One will refer to documentation [U4.42.03] for more details concerning the use of DEFI\_COQU\_MULT.*

### ***2.2.4 Limiting loadings and conditions: AFFE\_CHAR\_MECA and AFFE\_CHAR\_MECA\_F***

*The assignment of the loadings and the boundary conditions on a mechanical model is carried out with assistance of operators AFFE\_CHAR\_MECA, if loadings and boundary conditions mechanical on a system are actual values depending on no parameter, or AFFE\_CHAR\_MECA\_F, if these values are functions of the position or the increment of loading.*

## *FORCE\_ARETE*

*Key word factor usable to apply linear forces to an edge of an element of hull. For the linear elements the equivalent returns to apply a nodal force to the nodes supports of the element. There is not thus no the particular dedicated term. On the other hand, it requires elements of edges.*

## *FORCE\_COQUE*

*Key word factor usable to apply surface efforts (pressure by example) on elements defined on all the grid or one or several meshes or of the groups of meshes. These efforts can be given in the total reference mark or a reference mark of reference defined on each net or groups meshes; this reference mark is built around the normal with the element of hull and a fixed direction (see paragraph [2.2.2](#)).*

## *GRAVITY*

*Key word factor usable for a loading of the gravity type.*

## *PRES\_REP*

*Key word factor usable to apply a pressure to one or more meshes, or of the groups of meshes.*

## *ROTATION*

*Key word factor usable to calculate the loading due to the rotation of structure.*

## *TEMP\_CALCULEE*

*Allows to recover the thermal loading resulting from a thermal calculation linear or not linear. This functionality is useful for the chainings thermomechanical, not which will be approached in paragraph [4](#).*

## *EPSI\_INIT*

*Key word factor usable to apply a loading of deformation initial.*

### **Note:**

*The efforts of pressure being exerted on the elements of plates can apply is by FORCE\_COQUE (near) is by PRES\_REP. The user will have to thus pay attention (in version 5) not to twice apply the loading of pressure for the elements concerned, especially whenever modelings of plates would be mixed with other modelings using PRES\_REP.*

*In addition it should be noted that efforts of pressure, whether it is with FORCE\_COQUE (near) or PRES\_REP are such as a positive pressure acts in the contrary direction with that of the normal with the element. By defect, this normal is dependent on the direction of course of the nodes of an element, it who is not always very easy for the user. Moreover it is necessary that this one makes sure that all these elements are directed same manner. One thus advises to impose the orientation of these elements by the means of operator ORIE\_NORM\_COQU of order MODI\_MAILLAGE (see paragraph [§2.2.2]).*

#### ***2.2.4.5 Connections hulls with other machine elements***

*These connections must meet the requirements established in [bib4] and that one finds in particular in the connection 3d-BEAM in [R3.03.03].*

*The connections available with the elements of plates and hulls are as follows:*

*.*

*Connection Beam-**Hull**: it is a question of establishing the connection between a node end of an element of*

*beam and a group of meshes of edge of elements of hulls. Theories of beam and of plate know only normal cuts with fibre or the average surface.*

*connections can take place only according to these average fibres or surfaces. The connection beam-hull is **realizable for beams whose neutral fibre is orthogonal with***

***normals with the facets of the plates or the hulls**. To extend to other configurations*

*(a beam arriving perpendicular to the plan of a plate for example) request one*

*feasibility study because the elements of plate or hull do not have rigidity associated with*

*a rotation in the plan perpendicular to the normal on the average surface. The connection is*

*usable by using key word LIAISON\_ELEM: (OPTION: "COQ\_POU") of*

*AFFE\_CHAR\_MECA.*

*.*

*Connection Hull-**Pipe**: it is a question of establishing the connection between a node end of an element of*

*pipe and a group of mesh of edge of elements of hulls. The formulation of the connection*

*hull-pipes is presented in the reference document [R3.08.06]. Theories of pipe*

*and of plate, know only normal cuts with fibre or the average surface.*

*The connections can take place only according to these average fibres or surfaces. The connection*

*hull-pipe is realizable for pipes whose neutral fibre is orthogonal with the normals*

*with the facets of the plates or hulls. The connection is usable by using the key word*

*LIAISON\_ELEM: (OPTION: "COQ\_TUYAU") of AFFE\_CHAR\_MECA.*

*N*

*N normal with the facet of the hull = tangent to the beam*

*Connection hull - pipe*

*Connection plates or hull - beam*

## **Appear 2.2.4.5 - has: Connections hulls with other machine elements**

.  
*Connection **Hull massive 3D**: the connection massive hull-3D is being studied but it will be limited initially with the cases where the normal with the solid is orthogonal with the normal with the one facets of the element of plate or hull (see [bib4]).*

.  
*Connection **between elements of Hulls**: to connect two elements of hulls between them, one uses key word **LIAISON\_COQUE** of **AFFE\_CHAR\_MECA** (**\_F**) (documentation [U4.44.01]). This connection is carried out by means of linear relations. The traditional approach admits that 2 plans with a grid in hulls are cut according to a line which belongs to the grid of structure. In order to prevent that the volume which is the intersection of the 2 hulls is counted twice, one stops the grid of a hull perpendicular to a hull given to the level of the skin higher or lower of the latter. On [2.2.4.5 Figure - B], the connection between the 2 hulls is done by connections of solid body between the nodes in with respect to the A1 segments A2 and B1 B2.*

*displacements and large rotations available with incrémentaux behaviors nonlinear, but into small deformations*

COMP\_ELAS  
RELATION ELAS

(large  
DEFORMATION: '

•  
  
*deformations) GREEN\_GR'*  
TYPE\_CHARGE: 'Following Pressure

•  
  
SUIV'

*All the mechanical nonlinear behaviors of plane constraints of the code are accessible. One distinguishes the incremental relations of behavior (key word factor COMP\_INCR) from the relations nonlinear elastic behaviors (key word factor COMP\_ELAS). The relation of behavior connect the rates of deformation to the rates of constraints.*

*For modeling ROASTS reinforced concrete structures, the nonlinear behaviors correspond to particular incrémentaux behaviors in STAT\_NON\_LINE (COMP\_INCR):*

*GRILLE\_ISOT\_LINE for plasticity with isotropic work hardening,*

*GRILLE\_ISOT\_CINE for plasticity with kinematic work hardening linear Bi,*

*GRILLE\_PINTO\_MEN for the behavior of Pinto Menegotto.*

*Moreover, the behavior of the average concrete layer is given by a law of the type NADAI\_B.*

*The concept RESULT of STAT\_NON\_LINE contains fields of displacements, constraints and variables intern at the points of integration always calculated at the points of gauss:*

*DEPL: fields of displacements.*

*SIEF\_ELGA: Tensor of the constraints by element at the points of integration (COQUE\_3D and DKT) in the local reference mark. For each layer, one stores in the thickness and for each thickness on the points of surface integration. Thus if one wants information on one constraint for layer NC, on level NCN (NCN = -1 so the lower, NCN = 0 if medium, NCN = +1 so higher) for the surface point of integration NG, it will be necessary to look at the value data by the point defined in the option NOT such as*

*: NP = 3\* (NC-*

*1) \*NPG+ (NCN+1) \*NPG+NG where NPG is the total number of points of surface integration of*

*the element of COQUE\_3D (7 for the triangle and 9 for the quadrangle) and of element DKT.*

U2.02.01-A Page

: 24/50

*VARI\_ELGA: Field of variables intern (DKT and COQUE\_3D) by element at the points of surface integration. For each point of surface integration, one stores them information on the layers while starting with the first, level "INF". The number of variables represented is worth thus  $2*NCOU*NBVARI$  where NBVARI represents the number of internal variables.*

*It can be enriches by the following fields, calculated in postprocessing by operator CALC\_ELEM:*

*SIEF\_ELNO\_ELGA: activate the calculation of the tensor of the efforts generalized by element with nodes (membrane efforts, bending moments, sharp efforts), in the reference mark user (defined in the paragraph [§2.2.2]).*

*VARI\_ELNO\_ELGA: activate the calculation of the field of internal variables by element with the nodes in the thickness (by layer SUP/MOY/INF in the thickness except indication).*

### **2.3.2.2 Detail on the points of integration**

*For non-linear calculations the method of integration for the elements of plate and hulls is a method of integration by **layers**, of which the number is defined by the user. For each sleep, except modeling ROASTS, one uses a method of Simpson at three points of integration, with medium of the layer and in skins higher and lower of layer. For NR layers the number of points of integration in the thickness is of  $2N+1$ .*

*To treat non-linearities material, one advises to use from 3 to 5 layers in the thickness for a number of points of integration being worth 7, 9 and 11 respectively. For tangent rigidity, one calculates for each layer, in plane constraints, the contribution to the matrices of rigidity of membrane, of inflection and of coupling membrane-inflection. These contributions are added and assembled to obtain the matrix of total tangent rigidity. For each layer, one calculates the state of the constraints and the whole of the internal variables, in the middle of the layer and in skins higher and lower of sleep. This information is available in VARI\_ELGA and SIEF\_ELGA. The behavior plastic does not include/understand the transverse terms of shearing which are treated in an elastic way, because transverse shearing is uncoupled from the plastic behavior.*

*For modeling ROASTS reinforced concrete structures, it has only one point of integration there by sleep.*

### **Geometrical 2.3.2.3 non-linear Behavior**

*Calculations into non-linear geometrical (great displacements and great rotations), available with modeling COQUE\_3D, are carried out using operator STAT\_NON\_LINE, by using it*

key word *COMP\_ELAS*, as illustrated in the following example:

```
STAT_NON_LINE (  
COMP_ELAS (RELATION: "ELAS"  
COQUE_NCOU: 3  
DEFORMATION: "GREEN_GR")  
)
```

or by using an incremental behavior (key word *COMP\_INCR*) in small deformations.

It is possible to apply to the elements of *COQUE\_3D*, the following pressures. This loading has the characteristic to follow the geometry of the structure during its deformation (for example: hydrostatic pressure remains always perpendicular to the deformed geometry). To take in count this type of loading, it is necessary to specify in operator *STAT\_NON\_LINE* information following:

```
STAT_NON_LINE (  
EXCIT (LOAD: near  
TYPE_CHARGE: "SUIV")  
)
```

The geometrical non-linear behavior of the structures can have instabilities (buckling, snap-through/snap-back...). The determination and the passage of these limiting points, cannot be obtained by imposing the loading, however options of piloting of loading "*DDL\_IMPO*" or "*LONG\_ARC*" of operator *STAT\_NON\_LINE* make it possible to cross these critical points.

### **2.3.2.4 Buckling linear**

*Calculations in linear buckling are similar to the search of Eigen frequencies and modes of vibration. The problem has to solve is expressed in the form:*

*To find  $(\lambda, X)$   $(R, RN)$  such as  $AX = \lambda BX$*

*where  $A$  is the matrix of rigidity*

*$B$   
is the geometrical matrix of rigidity (calculated with option `RIGI_GEOM` of `CALC_MATR_ELEM`)*

*$\lambda$  is the critical load*

*$X$  is the mode of buckling associated with the critical load*

*Operators `MODE_ITER_INV` [U4.52.04] and `MODE_ITER_SIMULT` [U4.52.03] are used to determine the critical load and the mode of associated buckling.*

## **2.4 Additional calculations and postprocessings**

### **2.4.1 Elementary calculations of matrices: operator `CALC_MATR_ELEM`**

*Operator `CALC_MATR_ELEM` (documentation [U4.61.01]) allows to calculate matrices elementary, which is then gatherable by order `ASSE_MATRICE` (documentation [U4.61.22]).*

*The elementary options of operator `CALC_MATR_ELEM` are described below:*

**`CALC_MATR_ELEM COQUE_3D`**

**`DKT DST`**

**`Q4G`**

**`COQUE_C_PLAN`**

**`ROAST`**

**2.4.2 Calculations by elements: operator CALC\_ELEM**

*One presents hereafter the options of postprocessing for the elements of plates and hulls. They correspond to the results which a user can obtain after a thermomechanical calculation (internal constraints, displacements, deformations, variables, etc...). For the modelled structures by elements of hulls or beams it is particularly important to know how are presented results of constraints in order to be able to interpret them correctly. Approach adopted in Code\_Aster consists in observing the constraints in a particular reference mark related to the element whose reference axis was defined in the paragraph [§2.2.2]. Indeed, for a structure cylindrical the constraints easiest to interpret are not the constraints in Cartesian reference mark but constraints in cylindrical co-ordinates. Moreover this approach allows larger flexibility in use.*

*The produced concept is of type counts.*

*To use POST\_RELEVE\_T, it is necessary to define three concepts:*

.

**a place:** *the option NODE (example: N01 N045) or option GROUP\_NO (example: SUPPORT);*

.

**an object:** *with the choice, the option RESULT (SD result: EVOL\_ELAS,...) or the option CHAM\_GD (CHAM\_NO: DEPL,... or CHAM\_ELEM: SIGM\_ELNO\_DEPL,...) ;*

.

**a nature:** *with the choice, the option “EXTRACTION” (value,...) or the “AVERAGE” option (average, maximum, mini,...).*

### **Important remark:**

*If one comes from an interface with a maillor (PRE\_GIBI, PRE\_IDEAS, PRE\_GMSH), the nodes are arranged by numerical order. It is necessary to reorder the nodes along the line of examination. The solution is to use operator DEFI\_GROUP with option NOEU\_ORDO. This option makes it possible to create an ordered GROUP\_NO containing the nodes of a whole of meshes made of segments (SEG2ou SEG3).*

*An example of extraction of component is given in case-test SSNL503 (see description with [paragraph \[§2.5.3\] page 34](#)):*

```
TAB_DRZ=POST_RELEVE_T (ACTION=_F (  
GROUP_NO = “Of,  
ENTITLE = “TB_DRZ”,  
RESULT = RESUL,
```

```
NOM_CHAM = "DEPL",  
NOM_CMP = "DRZ",  
TOUT_ORDRE = "YES",  
OPERATION = "EXTRACTION"  
)  
)
```

*The purpose of this syntax is:*

- *to extract:*  
*OPERATION = "EXTRACTION"*
- *on the group of nodes D:*  
*GROUP\_NO = "Of*  
·  
*component DRZ of displacement: NOM\_CHAM = "DEPL", NOM\_CMP = "DRZ",*  
·  
*for every moment of calculation:*  
*TOUT\_ORDRE = "YES"*

#### ***2.4.7 Impression of the results: operator IMPR\_RESU***

*Operator IMPR\_RESU allows to write the grid and/or the results of a calculation on listing with the format*

*"RESULT" or on a file in a displayable format by external tools for postprocessing with Aster: format RESULT and ASTER (documentation [U4.91.01]), format CASTEM (documentation [U7.05.11]), format ENSIGHT documentation [U7.05.31]), format IDEAS (documentation [U7.05.01]), format MED (documentation [U7.05.21]) or format GMSH (documentation [U7.05.32]).*

*Currently this procedure makes it possible to write with the choice:*

- *a grid,*
- *fields with the nodes (of displacements, temperatures, clean modes, modes statics,...),*
- *fields by elements with the nodes or the points of GAUSS (of constraints, efforts generalized, of variables intern...).*

*Elements of plate and hull being treated same manner that other finite elements, us*

*let us return the reader to the notes use corresponding to the format of exit which it wishes to use.*

## **2.5 Examples**

*The case-tests selected here are traditional case-tests resulting from the literature and which are usually used to validate this type of elements.*

*It is pointed out that modelings DKT correspond to the theory of Coils-Kirchhoff and them DST modelings, Q4G with the theory with transverse energy of shearing (Reissner). Results for modeling COQUE\_3D are presented only for one theory with energy of shearing transverse.*

### **3 Thermics**

***For the resolution of chained thermomechanical problems, one must use for thermal calculation finite elements of thermal hull [R3.11.01]. These elements are elements plates, or linear in the case of structures of revolution or invariant structures along an axis. curve of the structure is not taken into account in itself. The metric one of the tangent plan of each element is calculated by supposing that all the tops are coplanar. These elements suppose a distribution a priori parabolic of temperature in the thickness, which results from one asymptotic development in linear thermics for a low thickness of hull, when them variations in temperatures are not too important. It is it should be noted that a model based on one development of the richer field of temperature in the thickness sees its terms of a higher nature to two to converge towards zero when the hull is thin. One cannot thus deal with the problems of thermal shocks with strong variation of the profile of temperature in the thickness with these hulls. methods of use of these elements are presented in [U1.22.01].***

**4 Chaining**

***thermomechanics******4.1 Formalism***

*For the resolution of chained thermomechanical problems, one must use for thermal calculation finite elements of thermal hull [R3.11.01] whose field of temperature is recovered like input datum of the Code \_Aster for mechanical calculation. It is necessary thus that there is compatibility between thermal field given by the thermal hulls and that recovered by the mechanical hulls. It the last is defined by the knowledge of 3 fields TEMP\_SUP, TEMP and TEMP\_INF given in skins lower, medium and higher of hull. The table below indicates these compatibilities:*

***Modélisation Maille Element Nets Element Modeling******THERMICS******MECHANICS******HULL QUAD9******THCOQU9******QUAD9******MEC3QU9H******COQUE\_3D******HULL QUAD8******THCOQU8******HULL QUAD4******THCOQU4******QUAD4******MEDKQU4******DKT******MEDSQU4******DST******MEQ4QU4******Q4G******HULL TRIA7******THCOTR7******TRIA7******MEC3TR7H******COQUE\_3D******HULL TRIA6******THCOTR6******HULL TRIA3******THCOTR3******TRIA3******MEDKTR3***

COQUE\_D\_PLAN  
SEG3  
METCSE3  
COQUE\_C\_PLAN  
COQUE\_AXIS SEG3 THCASE3  
SEG3 MECXSE3  
COQUE\_AXIS

**Note:**

.

*Nodes of the thermal elements of hulls and plates or hulls mechanics must correspond. Grids for thermics and mechanics the same number and the same type of meshes will thus have.*

.

*The elements of thermal hulls surface are treated like plane elements by projection of the initial geometry on the level defined by the first 3 tops. For the chaining of calculations with mechanical curved elements it is thus necessary that the geometry of the plate is not too distant from that of the hull. When structure is curved, that thus requires for thermal calculation to net it way sufficient fine in order to have correct results in preparation for the part mechanics. Only the linear elements of thermics are associated perfectly corresponding linear elements in mechanics fascinating bus of account curve of the structure with a grid.*

.

*The chaining with multi-layer materials is not available for the moment.*

.

*The thermomechanical chaining is also possible if one knows, analytically or by experimental measurements, variation of the field of temperature in the thickness of the structure or certain parts of the structure. In this case one works with one chart of temperature defined a priori; the field of temperature is not given any more by three values TEMP\_INF, TEMP and TEMP\_SUP of thermal calculation obtained by EVOL\_THER. Operator DEF1\_NAPPE allows to create such profiles of temperatures with to leave the data provided by the user. These profiles are affected by the order CREA\_CHAMPS and CREA\_RESU (cf the case-test hsns100b). It will be noted that it is not necessary for mechanical calculation that the number of points of integration in the thickness is equal to the number of points of discretization of the field of temperature in the thickness. The field of temperature is automatically interpolated at the points*

*of integration in the thickness of the elements of plates or hulls.*

### ***Appear 5-a: Fields of application of the plates and the hulls***

*Some recommendations concerning the field of application of these elements:*

.

***Mean structures:*** for these structures, whose  $h/L$  report/ratio is lower than  $1/20$ , effects of transverse shearing can be neglected and the theory of Kirchhoff applies. One advises to use for this type of structure of the elements plates *DKT-DKQ* or the elements of hull curve (*COQUE\_3D, \_AXIS, \_C\_PLAN, \_D\_PLAN*). **It is advised to use them preferably elements *DKT* and *DKQ*** which give very good results on displacements and more approximate on the constraints (to be recommended for the vibratory analyses). Even if one must to use a great number of these elements, the execution times remain reasonable compared with those of the curved elements.

.

***Thick structures:*** for these structures, one will use elements of *DST* plate, *DSQ* and *Q4G* who take account of transverse shearing with a factor of correction of shearing  $K = 5/6$  (theory of Reissner) or **preferably of the elements of curved hull**. It makes it possible to pass of a theory of Hencky-Mindlin-Naghdi for  $k=1$ , with a theory of Reissner for  $k=5/6$ . One value of  $K = 5/6$  is advised. By defect the coefficient of shearing is put at  $5/6$ . This preference rests on the fact that elements *DST, DSQ* and *Q4G* estimate them relatively badly efforts compared to the curved elements of hull, like one could notice it on certain cases tests of the paragraph [§2.5].

*Author (S):*

***A. ASSIRE, P. MASSIN, F. LEBOUVIER*** Key

:

*U2.02.01-A Page*

*: 48/50*

*Elements DKT, DKQ, DST, DSQ and Q4G are plane elements, they do not take into account curve of the structures, it is thus necessary to refine the grid if the curve is important if one wants to avoid the parasitic inflections.*

*Variation of metric of the geometry (i.e. its radius of curvature) according to sound thickness is taken into account:*

*.  
automatically for modeling COQUE\_3D*

*.  
defined by the user for modelings COQUE\_AXIS, COQUE\_D\_PLAN and COQUE\_C\_PLAN.*

***The optimal machine element in statics according to the whole of the case-tests of the paragraph [§2.5] is the element of hull with 9 nodes MEC3QU9H, which makes it possible to obtain good displacements and good constraints thanks to its P2 interpolation out of membrane. It is a general-purpose element which can be at the same time used to represent very mean structures (h/L 1/100) or thicker. Like, in addition, the element of hull with 7 nodes MEC3TR7H is less powerful, it is advised with the user to net his structure in hulls with the greatest possible number quadrangles.***

*.  
**Non-linearity material:** nonlinear behaviors (plasticity, etc) in plane constraints are available for the elements of hull curves (COQUE\_3D, COQUE\_AXIS, COQUE\_C\_PLAN, COQUE\_D\_PLAN) and the elements plates DKT-DKQ only. The plastic behavior does not take the terms of transverse shearing which are treated in an elastic way, because it transverse shearing is uncoupled from the plastic behavior. For a good representation progression of plasticity through the thickness, one advises to use for integration numerical 3 to 5 layers in the thickness for a number of points of being worth gauss respectively 3, 5 and 11.*

*.  
**Geometrical non-linearity:** nonlinear behaviors (great displacements large rotations) in plane constraints are available for the elements of curved hull COQUE\_3D only.*

*.  
**Buckling of Euler:** this type of analysis is available with the elements of curved hull COQUE\_3D only.*

*Elements corresponding to the machine elements exist in thermics; couplings thermomechanical are thus available at the same time for the elements of plates and hulls. For the moment these couplings are not possible for multi-layer materials.*

## 1 Introduction

*Finite elements TUYAU\_3M and TUYAU\_6M correspond to linear elements of piping right-hand side or curve. They are based on a kinematics of beam of Timoshenko for displacements and rotations of average fibre and on a kinematics of hull for the deformations of transverse section (ovalization, warping, swelling). These transverse deformations are broken up into Fourier series. Modeling TUYAU\_3M takes into account 3 modes with maximum, while modeling TUYAU\_6M takes into account 6 modes of Fourier.*

*These modelings are usable for problems of three-dimensional pipings relatively thick, only in linear mechanical analysis or not linear and small displacements. Currently, no calculation of thermics or acoustics is possible.*

*This document presents the possibilities of modeling PIPE available in version 6 of Code\_Aster. One initially presents the possibilities of this type of modeling, then one briefly points out the formulation of the finite elements and their differences with modelings beam. One also gives the list of the options available for each element. One finishes by the presentation of some academic case-tests and finally one gives some councils of use.*

*The right or curved pipe sections are gathered under modelings TUYAU\_3M and TUYAU\_6M. The options of calculations are defined in this document. Current possibilities of these elements pipes are as follows:*

- .  
*right or curved lines of piping,*
- .  
*linear element with 3 nodes (SEG3) or 4 nodes (SEG4),*
- .  
*relatively thick pipe:  $e/R < 0.2$  where  $E$  represents the thickness and  $R$  the ray of the section transverse,*
- .  
*internal pressure, cross-bendings and anti-plane, torsion and extension,*
- .  
*small displacements,*
- .  
*elastoplastic in plane constraints, or not linear behavior incremental unspecified,*
- .  
*the transverse section can become deformed by:*
- *swelling due to the internal pressure or the effect Poisson,*

-  
ovalization due to the inflection,  
-

warping due to the inflections combined in the plan and except plan.

Compared with modeling TUYAU\_3M, modeling TUYAU\_6M allows the best approximation of the behavior of the cross section if this one becomes deformed according to a mode raised, for example in the case of thin tubes where the thickness report/ratio on ray of cross section is  $< 0.1$ , and in the case of plasticity.

Modeling TUYAU\_3M has 21 DDL per node (6 DDL of beam and 15 DDL of hull), tandis that modeling TUYAU\_6M has 39 DDL per node (6 DDL of beam and 33 DDL of hull).

For modeling TUYAU\_3M, one can use meshes SEG3 and SEG4.

**Capacities of modeling**

2.1

**Recall of the formulation**

**2.1.1 Geometry of the elements pipes**

We point out here the methods and the modelings implemented for the elements pipes and which are presented in the reference document [R3.08.06].

*For the elements pipes one defines an average, right fibre or curve (X defines the co-ordinate curvilinear) and a section dig of circular type. This section must be small compared to length of piping. The figure [Figure 2.1.1-a] illustrates the two various configurations. One locate local oxyz is associated average fibre.*

***Appear 2.1.1-a: Right pipe or curve***

### ***2.1.2 Formulation of the elements pipes***

*The kinematics of the pipe [Figure 2.1.2-a] is composed of a kinematics of hull which brings description of ovalization, swelling and warping, and a kinematics of beam which described the overall movement of the line of piping. Displacement U [Figure 2.1.2-b] of one not material of the pipe of a macroscopic part beam is composed (UP) and of a part additional local hull (US):  $U = UP + US$*

### ***Appear 2.1.2-a: Decomposition of displacement in fields of beam and hull***

*The formulation of the elements rests on:*

***The theory of the beams*** for the kinematics of average fibre. If one makes the complete assumption of theory of the beams: cross-sections associated displacements of beam (UP), which are perpendiculars with **average fibre** of reference [Figure 2.1.2-b] remain perpendicular to fibre average after deformation. The cross-section does not become deformed. This will be true on average in the element PIPE. One uses the theory of the beams only to describe the movement of fibre average: the average fibre of the pipe is equivalent to average fibre of a beam. This kinematics makes it possible to describe the overall movement of the line of piping.

***The theory of the hulls*** to describe the transverse deformation of the sections around fibre average. Kinematics of the transverse sections: the cross-sections which are perpendicular to **surface average** reference remain right. Material points located on the normal at surface not deformed average remain on a line in the deformed configuration. The formulation used is a formulation of the type LOVE\_KIRCHHOFF without transverse shearing for the description of behavior of the transverse sections. The thickness of the hull remains constant. Surface average of the pipe, located at mid thickness, is equivalent to the average surface of a hull. This kinematics of hull brings the description of swelling, the ovalization and the warping of cross section.

*Additional displacements (Custom) of the surface of the pipe are approximated by a series of Fourier until the order M (M=3 for modeling TUYAU\_3M and M=6 for modeling TUYAU\_6M).*

*M**M**S* $U(X, \theta) = I$  $U(X) \cos m \theta +$  $u_0(X) \sin m \theta$ *m**m**m=2**m=2**M**M**S* $v(X, \theta) = I$  $W(X) \sin m \theta +$  $w_0(X) \cos m \theta +$  $v_0(X) \cos m \theta$ *m**m**m=2**m**m**iv X m -**m**m**m=2**m=2*

*M**M**S*

$$W(X, \cdot) = w_0 + I$$

$$W(X) \cos m +$$

$$w_0(X) \sin m$$

*m**m*

$$m=2$$

$$m=2$$

*Where*

*custom:* represent the axial displacement of average surface in the local reference mark *X*

*vs:* represent orthoradial displacement average surface in the local reference mark *X*

*ws:* represent the radial displacement of average surface in the local reference mark *X*

*w0:* represent swelling

*These elements thus utilize locally:*

*6 variables kinematics for the beam formulation: up displacements, vp and wp according to fibre of reference and rotations around the local axes,*

*3 variables kinematics for the hull formulation: additional displacements custom, vs and ws in the reference mark of average surface,*

*4 constraints in the thickness of pipe noted SIXX (sxx), SIYY (sff), SIXY (sxf), and SIXZ (sxz). Constraint SIZZ (szz) is null (assumption of plane constraints). Constraints of shearing transverses are null (assumption of Coils Kirchoff),*

*4 deformations in the thickness of pipe noted EPXX (exx), EPYY (EFF), EPXY (exf), and EPXZ (sxz). Deformation EPZZ (ezz) is null for the beam part.*

***Important remark:***

*The kinematics of beam is based on the assumption of Timoshenko [R3.08.03]. The element pipe is not "exact" with the nodes for loadings or torques concentrated at the ends, it is necessary to net with several elements to obtain correct results.*

*According to average fibre, these elements are of isoparametric type. It results from it that them displacements vary like polynomials of order 2 following X for the elements with 3 nodes and*

*of order 3 per 4 nodes.*

## **2.2**

### ***Comparison with other elements***

#### ***2.2.1 Differences between the elements pipes***

*The elements pipes TUYAU\_3M and TUYAU\_6M are linear elements:*

.

*TUYAU\_3M with three or four nodes*

.

*TUYAU\_6M with four nodes*

*These elements are different only on the level from the approximation from the field from displacement additional HULL, which is made by a decomposition in Fourier series:*

.

*TUYAU\_3M until order 3*

.

*TUYAU\_6M until order 6*

*Instruction manual*

**A. ASSIRE, P. MASSIN, F. LEBOUVIER** *Key*

.

*U2.02.02-A Page*

*: 8/32*

*Consequently the number of DDL is different:*

.

*TUYAU\_3M 21 per node (6 DDL of beam and 15 DDL of hull)*

.

*TUYAU\_6M 39 per node (6 DDL of beam and 33 DDL of HULL)*

*Compared with modeling TUYAU\_3M, modeling TUYAU\_6M allows the best approximation of the behavior of the cross section if this one becomes deformed according to a mode raised, for example in the case of thin tubes where the thickness report/ratio on ray of cross section is  $< 0.1$ , and in certain cases in plasticity.*

### ***2.2.2 Differences between the elements pipes and the elements beams***

*Like the finite elements PIPE, the finite elements BEAM also form part of the class of linear finite elements. One compares in this part the applicable formulations and loadings for these two classes of elements.*

*On the level of the **formulation**:*

.

#### ***Element BEAM:***

*The formulation is based on an exact resolution of the equations of the continuous model carried out for each element of the grid. Several types of elements of beam are available:*

-

*POU\_D\_E: transverse shearing is neglected, as well as the inertia of rotation. This assumption is checked for strong twinges (Assumption of Euler),*

-

*POU\_D\_T, POU\_C\_T: transverse shearing and all the terms of inertia are taken in count. This assumption is to be used for weak twinges (Assumption of Timoshenko).*

*These elements use meshes of the type SEG2 with 6 DDL by nodes, 3 displacements and three rotations. The formulation of these elements is presented in the reference document [R3.08.01]. The section is constant, the only possible behavior of the transverse sections is the translation and rotation for the whole of the points of the section. The section perhaps of an unspecified form constant or variable over the length.*

.

#### ***Element PIPE:***

*The formulation combines at the same time a beam formulation based on the assumption of Timoshenko and a hull formulation based on the assumption of Love\_Kirchhoff allowing to model phenomena of swelling, ovalization and warping. The hollow section, of form circular, is constant over the entire length of the element. The element is not “exact” for the nodes for loadings or torques concentrated at the ends, it is necessary*

*thus to net with several elements to obtain correct results.*

*These elements use meshes of the type SEG3 or SEG4 with, for the kinematics of beam 6 DDL by nodes, 3 displacements and three rotations, and for the kinematics from hull, 15 or 33 DDL to typify displacement.*

*On the level of the **applicable loadings**:*

.

### **Element BEAM:**

*The possible loadings are the loadings of extension, inflection and torsion. internal loading of pressure for the hollow sections does not exist (the section is indeformable).*

.

### **Element PIPE:**

*The element PIPE admits the traditional loadings of beam as well as the application of one internal pressure.*

## **3 Description of the command sets**

### **3.1**

## ***Assignment of a modeling and space discretization***

*In this part, one describes the choice and the assignment of one of two modelings PIPE as well as degrees of freedom and associated meshes. The majority of described information are extracted from documentation of use [U3.11.06]: Modelings TUYAU\_3M and TUYAU\_6M.*

### ***3.1.1 Degrees of freedom***

*The degrees of freedom are, in each node of the mesh support:*

- 
- six components of displacement of average fibre (three translations and three rotations),*
- 
- three degrees of freedom corresponding to modes 0 and 1,*
- 
- for each mode of Fourier, 6 degrees of freedom (U corresponds to warping, V and W with ovalization: V with displacement orthoradial, W with radial displacement, I means “in plane” and O mean “out of plane”).*

#### ***Element***

### ***3.1.2 Net support of the matrices of rigidity***

*The meshes support of the finite elements, in displacement formulation, are segments with 3 or 4 nodes.*

#### ***Modeling Nets Element***

***finished***

***Remarks***

*TUYAU\_3M SEG3 METUSEG3*

*Linear mesh*

*SEG4*

*MET3SEG4*

*Linear mesh*

*TUYAU\_6M SEG3 MET6SEG3*

*Linear mesh*

*The meshes SEG4, which have cubic functions of forms, were developed to solve one simple problem of beam in inflection. For this simple example, the exact solution is obtained with the assistance of only one element with mesh SEG4.*

*For more complex problems, the experiment shows that one can net much more coarsely with meshes SEG4. For example one needs about fifteen elements SEG3 to obtain a correct solution for an elbow in inflection whereas one needs of it half with elements SEG4.*

**Note:**

*One can use operator MODI\_MAILLAGE to build meshes SEG4 from meshes SEG3.*

**3.1.3 Net support of the loadings**

*All the loadings applicable to the elements used are treated by direct discretization on net support of the element in displacement formulation. Linear pressure and other forces as well as gravity are examples of loadings applying directly to the element. No special mesh of loading is thus necessary.*

**3.1.4 Model**

**:  
AFFE\_MODELE**

*The assignment of modeling passes through operator AFFE\_MODELE [U4.41.01]. It is pointed out that only the mechanical phenomenon is available with the element PIPE.*

**AFFE\_MODELE**

**TUYAU\_3M  
Remarks**

**TUYAU\_6M**

**AFFE**

**PHENOMENON:  
"MECHANICAL"**

**MODELING "TUYAU\_3M"**

**MODELING "TUYAU\_6M"**

*On the level of the choice of modeling PIPE, one can note that the use of a decomposition in Fourier series to order 6 (element TUYAU\_6M) improve the approximation of the behavior of cross section if this one becomes deformed according to a raised mode, for example in mean cases of tubes where the thickness report/ratio on ray of the cross section is  $< 0.1$ , and in case of plasticity*

.  
*Definition of a generator. By*  
*defect, a generator is created*

*PRECISION*

.  
*CRITERION*

.  
*The characteristics which it is possible to affect on the elements PIPE, are:*

.  
*SECTION: “CIRCLE”*

*The section is defined by its ray “R” external and its thickness “EP”, on each mesh*  
*since the grid is represented by average fibre of the pipe.*

.  
*TUYAU\_NCOU: tncouch*

*It is the number of layers to be used for the integration of the relations of behavior not*  
*linear in the thickness of the right pipe sections. In linear elasticity, one to two*  
*layers are enough, into nonlinear one advises to put between 3 and 5 layers. The number of*  
*not Gauss is equal to twice the number of layers plus one ( $2 * tncouch + 1$ ), which makes*  
*that time CPU increases quickly with the number of the layers.*

.  
*TUYAU\_NSEC: tnsec*

*It is the number of angular sectors to use for the integration of the relations of nonlinear behavior in the circumference of the right pipe sections. By defect it a many sectors are worth 16. One advises to put 32 sectors into nonlinear for precise results (attention with the increase in time CPU with the number of sectors).*

### **ORIENTATION (“GENE\_TUYAU”)**

*One defines from one of the nodes ends of the line of piping a continuous line traced on the pipe. The operands **PRECISION** and **CRITERION** make it possible to define the precision for the construction of the generator and the limit enters a right pipe section and one curved element.*

#### **Note:**

*The directing vector of the line thus defined should not be colinéaire with average fibre of bend with the node end considered, by using the key word **INFORMATION: 2** one can check if it definite vector is correct.*

*Instruction manual*

### **3.2.1 Operand**

#### **MODI\_METRIQUE**

*Operand **MODI\_METRIQUE** makes it possible to define for the elements **PIPE** the type of integration in the thickness:*

·  
*MODI\_METRIQUE: “NOT” resulted in assimilating in integrations the ray to the ray means. This is thus valid for the pipes low thickness (relative with the ray),*

·  
*MODI\_METRIQUE: “YES” implies a complete integration, more precise for thick pipings, but being able in certain cases to lead to oscillations of solution.*

### **3.2.2 Generator and concept of local reference mark: key word *ORIENTATION***

*The generator traced throughout piping makes it possible to define the origin of the angles [Figure 2.1.2-b]. This is used:*

·  
*to interpret the degrees of freedom of ovalization;*

·  
*to choose the place of extraction of the constraints (option *SIGM\_ELNO\_TUYO*) and the variables interns (option *VARI\_ELNO\_TUYO*).*

· ·  
*Generating line*

2

·

·

· ·

1

#### ***Appear 3.2.2-a: Representation of two noncoplanar elbows connected by a right pipe.***

*For a transverse section end of the line of piping [Figure 3.2.2-b], the user defines in *AFFE\_CARA\_ELEM* under the key word *ORIENTATION* a vector of which projection on the section transverse end defines a unit vector origin  $zI$ .*

*Syntax is as follows:*

```
AFFE_CARA_ELEM (...
ORIENTATION: (GROUP_NO: END
CARA: “GENE_TUYAU”
VALE: (X, y, Z));
```

*where: END is the node centers transverse section end;*

*(X, y, Z) contains the 3 components of the vector directing the generator of the pipe, to project on the transverse section end. This vector must be defined in a node or a group\_no end of the pipe. The geometry is then built automatically for all the elements related of PIPE.*

*Instruction manual*

*U2.02 booklet: Elements of structure*

### **3.3 Materials**

**DEFI\_MATERIAU**

*The definition of the behavior of a material is carried out using operator DEFI\_MATERIAU [U4.43.01]. There is no particular constraint which had with the use of the elements PIPE.*

*The materials used with the whole of modelings can have elastic behaviors in plane constraints whose linear characteristics are constant or function of the temperature. The nonlinear behaviors in plane constraints are available for modelings pipes. For more information on these nonlinearities one can refer to [§ 2.6].*

### **3.4 Limiting loadings and conditions**

**: AFFE\_CHAR\_MECA and  
AFFE\_CHAR\_MECA\_F**

*One points out that it is not possible to carry out thermal calculations, however the assignment of temperature is possible, using operator CREA\_CHAMP. (see paragraph [§3.4.4]).*

*The assignment of the loadings and the boundary conditions on a mechanical model is carried out with assistance of operators AFFE\_CHAR\_MECA, if loadings and boundary conditions mechanical on a system are actual values depending on no parameter, or AFFE\_CHAR\_MECA\_F, if these values are functions of the position or the increment of loading.*

*The documentation of use of AFFE\_CHAR\_MECA and AFFE\_CHAR\_MECA\_F is [U4.44.01].*

#### **3.4.1 List key words factors of AFFE\_CHAR\_MECA and AFFE\_CHAR\_MECA\_F**

*The key words factors available for these two operators are gathered in the two tables following.*

**AFFE\_CHAR\_MECA TUYAU\_3M**

**Drank, remarks and examples**

**TUYAU\_6M**

**DDL\_IMPO**

.

**Drank:** *to impose, with nodes or groups of nodes, one or of the values of displacement*

*Mode 0 (swelling) and:*

-  
*modes 1 to 3 for TUYAU\_3M*

-  
*modes 1 to 6 for TUYAU\_6M*

**Example:** *SDLL14, SLL101, SSLX102, SSNL106,...*

**LIAISON\_DDL**

.

**Drank:** *to define a linear relation between degrees of freedom from two or several nodes*

**LIAISON\_OBLIQUE**

.

**Drank:** *to apply, with nodes or groups of nodes, even component value of displacement definite by component in an unspecified oblique reference mark*

## *LIAISON\_GROUP*

.

**Drank:** *to define linear relations between certain degrees of freedom of couples of nodes, these couples of nodes being obtained while putting in opposite two lists of meshes or of nodes*

## *LIAISON\_UNIF*

.

**Drank:** *to impose the same value (unknown) on degrees of freedom of a whole of nodes*

**Example:** *ELSA01B, ELSA01C and ELSA01D*

## *LIAISON\_SOLIDE*

.

**Drank:** *to model an indeformable part of a structure*

**Example:** *ELSA01B, ELSA01C and ELSA01D*

## *LIAISON\_ELEM*

.

**Drank:** *to model the connections of a massive part 3D with a pipe part or of a hull part with a pipe part*

**Example:** *SSLX101B, SSLX102A and SSLX102F*

## *LIAISON\_CHAMNO*

.

**Drank:** *to define a linear relation between all ddls present in a concept CHAM\_NO*

## *TEMP\_CALCULEE*

.

## **Drank**

*: to recover a thermal loading (temperature affected by CREA\_CHAMP)*

**Example:** *HSNS101D, HSNV100C, SSSL101C,...*

## *GRAVITY*

.

**Drank:** *to apply an effect of gravity*

**Example:** *SSSL101, SSSL106*

## *FORCE\_POUTRE*

.

**Drank:** *to apply linear forces, to elements of the type beam*

**Example:** *SSSL106*

## *FORCE\_NODALE*

.

**Drank:** *to apply, with nodes or groups of nodes, nodal forces, definite component by component in*

*TOTAL reference mark or in an oblique reference mark defined by 3 angles

*elbow is modelled with elements 3D.*

*In all these case-tests, the results are satisfactory given that part of the variations  
noted is ascribable with the fusion of the grid 3D or hulls.*

**Note:**

## Connections pipe-beams.

*It is a question of establishing a connection between a node end of a pipe section and a node end of one element of beam. The pipe formulation comprises a kinematics of the beam type identical to kinematics of the elements beams. There is thus no cut between displacements of the type beam (3 displacements and 3 rotations). The average fibre of the beam and the pipe are the same ones.*

*By*

*count, the kinematics of the elements of beam does not include/understand kinematics of hull (the section is indeformable) like in the case of the elements pipes, there is thus a cut on the level of deformation of the transverse section.*

*There does not exist in specific Code\_Aster of connection pipe-beam, the connection between these two elements is automatically assured, without intervention of the user, by the node common to the element pipe and with the element beam. Nevertheless, some care are to be taken, it is necessary that transition between the beam and pipe sections is sufficiently distant from all zones "pipe" or the deformation of the transverse section is significant, i.e. that one should connect only when ovalization is deadened.*

## **4 Resolution**

### **4.1**

***Linear calculations: Linear MECA\_STATIQUE and other operators***

***Linear calculations are carried out in small deformations. Several linear operators of resolution are available:***

.

***MECA\_STATIQUE: resolution of a problem of static mechanics linear ([U4.51.01]),***

.

***MACRO\_ELAS\_MULT: calculate linear static answers for various loading cases or modes of Fourier. ([U4.51.02]),***

.

***MODE\_ITER\_SIMULT: calculation of the values and vectors clean by methods of under spaces. ([U4.52.03]),***

.

***MODE\_ITER\_INV: calculation of the values and vectors clean by the method of iterations opposite ([U4.52.04]),***

**MODE\_ITER\_CYCL**

*: calculation of the clean modes of a structure with cyclic symmetry ([U4.52.05]),*

*DYNA\_LINE\_TRAN: calculation of the transitory dynamic response to a temporal excitation unspecified ([U4/U4.53.02]).*

*Concerning the operator of resolution of static mechanics linear, following information is extracted the documentation of use of operator MECA\_STATIQUE: [U4.51.01].*

**MECA\_STATIQUE**

**TUYAU\_3M**

**TUYAU\_6M**

**ANGLE**

*ndegré*

*This word is used only for the postprocessings required on pipe sections. It is the angle (in degrees) not compared to the generator of the circuit of piping. It is worth 0 per defect*  
**NUME\_COUCHE** *nume*

*This word is used only for the postprocessings required on pipe sections. It is the angle (in degrees) not compared to the generator of the circuit of piping. It is worth 0 per defect*  
**NIVE\_COUCHE** *“INF”*

*This word is used only for the postprocessings required on “SUP” pipe sections. It is the angle (in degrees) “MOY” not compared to the generator of the circuit of piping. It is worth 0 per defect*

*By defect, the only computed field is the fields of displacement DEPL. Other fields are available by the operand OPTION (see the options available in the paragraph [§5.2] bearing on the use of CALC\_ELEM).*

.  
**ANGLE:** /delta (0. per defect)

.  
**NUME\_COUCHE:** /nume (standard entirety, 1 per defect)

.  
**NIVE\_COUCHE:** /"INF", "SUP" or "MOY" ("MOY" by defect)

**with:**

.  
**delta:** angle in degrees counted starting from the position of the generator of the element pipe,

.  
**nume:** number of layer (number 1 corresponds to the internal layer). Must be inferior or equal to the total number of layers given in STAT\_NON\_LINE (key word TUYAU\_NCOU),

.  
**NIVE\_COUCHE** indicates the position of the point of integration in layer (INF corresponds to not more the intern).

**4.2**

**Nonlinear calculations: STAT\_NON\_LINE and DYNA\_NON\_LINE**

**4.2.1 Behaviors and assumptions of deformations available**

Following information is extracted from the documentation of use of the operator *STAT\_NON\_LINE*: [U4.51.03].

*STAT\_NON\_LINE*

*TUYAU\_3M*

*DYNA\_NON\_LINE*

*TUYAU\_6M*

*COMP\_INCR RELATION*

.  
*all behaviors available  
in C\_PLAN  
DEFORMATION SMALL*

.  
*Incremental relations of behavior (key word factor COMP\_INCR) according to the assumption of small displacements and small deformations (key word DEFORMATION: "SMALL") are only mechanical nonlinear relations of behavior available for modeling PIPE. These relations of behavior connect the rates of deformation to the rates of constraints. Behaviors nonlinear supported are those already existing in plane constraints defined in the operators STAT\_NON\_LINE and DYNA\_NON\_LINE. Moreover, with ALGO\_C\_PLAN: `DEBORST` all them behaviors 2D (D\_PLAN, AXIS) in small deformations are usable.*

*The options specific to modeling PIPE are:*

*The concept RESULT of STAT\_NON\_LINE contains displacement, stress fields and variables intern at the points of integration always calculated at the points of gauss:*

.  
*SIEF\_ELGA: Tensor of the constraints by element at the points of integration in the reference mark room of the element,*

.  
*VARI\_ELGA: Field of variables intern by element at the points of integration in locate local element,*

.  
*DEPL: fields of displacements.*

*Moreover, one call to operator CALC\_ELEM or CALC\_NO, gives access other fields. In particular, one can carry out the passage of the constraints and internal variables of the points of Gauss with the nodes to form fields SIEF\_ELNO\_ELGA and VARI\_ELNO\_ELGA (see the paragraph [§5.2]).*

*A field VARI\_... can have several types of components. For example, components of field VARI\_ELNO\_ELGA are, for the elements PIPE:*

*K time: (V1, V2, ..... Vn)*

*Where:*

*K is the number of points of integration total:  $K = (2 * NCOU + 1) * (2 * NSEC + 1)$ ;*

*NR is the number of variables intern and depends on the behavior.*

#### ***4.2.2 Details on the points of integration***

*For linear and non-linear calculations, numerical integration is carried out with a method of:*

*Gauss along average fibre.*

*The number of points of integration is fixed at 3. For a mesh whose tops are 1 and 2 and numbered from 1 to 2, the 3 points of gauss are such as first is close to 1, it second is at equal distance from 1 and 2 and the third is closer to 2. It is thus necessary to make attention with the orientation of the meshes when one looks at the results at the points of gauss 1 and 3. Indeed if the orientation of the mesh is changed and that one numbers it from 2 to 1, the first not gauss is closer to 2.*

U2.02.02-A Page

: 23/32

*Simpson in the thickness and on the circumference:*

-  
*Integration in the thickness is an integration of Simpson at 3 points per layer. a number of points of integration per layer is fixed at 3, in the middle of the layer, in skin higher and in lower skin of the layer, the two points ends being common with the close layers.*

-  
*Integration according to the circumference is an integration of Simpson per sector, each sector being of angle  $2/NSEC$ . is the angle between the generator and the center of the sector. The number of points of integration per sector is fixed at 3, in the middle of the sector, partly higher (+  $/NSEC$ ) and lower (-  $/NSEC$ ) of the sector, two points ends being common with the close sectors.*

*The number of layers and the number of sectors must be defined by the user starting from the key words: TUYAU\_NCOU, TUYAU\_NSEC of operator AFFE\_CARA\_ELEM.*

*For example, with 3 layers and 16 sectors, the number of points of integration per element is  $(2*NCOU+1) * (2*NSEC+1) *NPG$  what gives 693 points of integration. For each point of gauss on the length of the element, one stores information on the layers and for each layer on all sectors. If one wants information at the point of gauss NG, on layer NC level NCN (NCN = 1 so lower, NCN = 0 if medium, NCN = + 1 so higher), on the sector NS, level NSN (NSN = 1 so lower, NSN = 0 if medium, NSN = +1 so higher), then one looks at the values sought with not integration:*

$$NP = (NG-1) * (2NCOU+1) * (2NSEC+1) + (2*NC+NCN-1) * (2NSEC+1) + (2*NS+NSN).$$

*In practice, it is more convenient to observe:*

*that is to say values extracted in a thickness and a sector: \*\_TUYO;*

*maybe of the total values, for example SIEF\_ELNO\_ELGA.*

## **4.3 Calculations**

### **dynamic**

*Concerning dynamic calculations, no specificity due to the finite element PIPE exists.*

## **Additional calculations and postprocessings**

**5.1**

### **Elementary calculations of matrices: operator CALC\_MATR\_ELEM**

*Operator CALC\_MATR\_ELEM (documentation [U4.61.01]) allows to calculate matrices elementary gatherable by order ASSE\_MATRICE (documentation [U4.61.22]).*

*The only calculable matrices with the elements pipe are the matrices of rigidity and mass of elements of the model:*

***CALC\_MATR\_ELEM  
TUYAU\_3M  
TUYAU\_6M Remarks***

***“RIGI\_MECA”***

..

***“MASS\_MECA”***

..

*These calculations of elementary matrices for example are used for the determination of the frequencies clean of a thick cylindrical ring, in case-test SDLS109G.*

## **5.2 Calculations by elements: operator CALC\_ELEM**

*Operator CALC\_ELEM (documentation [U4.81.01]) carries out the calculation of the fields to the elements:*

- constraints, deformations, variables intern with the nodes;*
- equivalent values (nonavailable for modeling PIPE).*

*One presents hereafter the options of postprocessing for the pipe sections. For the structures modelled by pipe sections, it is particularly important to know how are presented results of the constraints: the approach adopted in Code\_Aster consists in observing constraints in a particular reference mark related to the element whose reference axis was defined in paragraph [§3.2.2]. This approach seems most physical because, for a cylindrical structure, them the constraints easiest to interpret are not the constraints in Cartesian reference mark but them constraints in cylindrical co-ordinates. Moreover this approach allows a greater flexibility of use.*

***CALC\_ELEM  
TUYAU\_3M TUYAU\_6M Remarks***

***“SIEF\_ELGA\_DEPL”***

..

***“EFGG\_ELNO\_DEPL”***

..  
“EPSI\_ELGA\_DEPL”

.

*VARI\_ELNO\_ELGA: calculation of the field of variables intern by element with the nodes to leave points of Gauss, for all the layers (in thickness SUP/MOY/INF) and for all sectors in the local reference mark of the element.*

.

*SIGM\_ELNO\_TUYO: calculation of the local constraints by elements with the nodes from points of integration, in the local reference mark of the element. Calculations provide the constraints at the point defined by options NUME\_COUCHE, NIVE\_COUCHE and ANGLE.*

.

*VARI\_ELNO\_TUYO: calculation of the variables intern **in a layer** and for a sector angular of elements pipe (key words NUME\_COUCHE, NIVE\_COUCHE and ANGLE affected by AFFE\_CARA\_ELEM, to see paragraph [§3.2]).*

*One obtains then by node of each tensor only one element of constraints (or only one whole of variables intern), which allows the graphic examination (evolution of a component,...).*

### 5.3

#### **Calculations with the nodes: operator CALC\_NO**

CALC\_NO  
TUYAU\_3M  
TUYAU\_6M Remarks

“FORC\_NODA”

..

“REAC\_NODA”

..

“EFGE\_NOEU\_DEPL”

..

“SIEF\_NOEU\_ELGA”

..

“VARI\_NOEU\_ELGA”

Operator *CALC\_NO* (documentation [U4.81.02]) carries out the calculation of the fields to the nodes by moyennation and the calculation of the forces and reactions:

fields with the nodes: internal constraints, deformations, variables, equivalent values;

Name of option: to replace *\_ELNO\_* by *\_NOEU\_*

One can calculate the fields with the nodes by *CALC\_NO*  
*SIEF\_NOEU\_ELGA*, *VARI\_NOEU\_ELGA*

forces and reactions:

starting from the constraints, balance: *FORC\_NODA* (calculation of the nodal forces from constraints at the points of integration, element by element),

then by removing the loading applied: *REAC\_NODA* (calculation of the nodal forces of reaction to the nodes, the constraints at the points of integration, element by element):

$REAC\_NODA = FORC\_NODA - \text{loadings applied}$ ,

useful for checking of the loading and calculations of resultants, moments, etc

## **5.4**

### ***Calculations of the elementary fields: operator CALC\_CHAM\_ELEM***

*Operator CALC\_CHAM\_ELEM (documentation [U4.81.03]) allows to calculate fields elementary starting from already calculated fields of type CHAM\_NO\_\* or CHAM\_ELEM\_\*.*

### ***TUYAU\_3M TUYAU\_6M Remarks***

*“EFGE\_ELNO\_DEPL”*

..

*For modeling PIPE, only the efforts generalized for a field of displacement are available.*

## **5.5 Calculations of quantities on whole or part of the structure: operator POST\_ELEM**

*Operator POST\_ELEM (documentation [U4.81.22]) allows to calculate quantities on all or part of the structure. The calculated quantities correspond to particular options of calculation of affected modeling.*

### ***TUYAU\_3M***

### ***TUYAU\_6M Remarks***

*“MASS\_INER”*

..

*For modeling PIPE, the only currently available option is calculation, on each element, of the mass, inertias and the position of the centre of gravity (option “MASS\_INER”).*

## **5.6 Values of components of fields of sizes: operator POST\_RELEVE\_T**

For modeling PIPE, operator *POST\_RELEVE\_T* (documentation [U4.81.21]) can be used for, on a line, to extract from the values (for example *SIEF\_ELNO\_ELGA* or *SIGM\_ELNO\_TUYO*). The produced concept is of type counts.

**Important remark:**

If one comes from an interface with a maillor (*PRE\_GIBI*, *PRE\_IDEAS*, *PRE\_GMSH*), the nodes of a groupno are arranged by numerical order. It is necessary to reorder the nodes along line of examination. The solution is to use operator *DEFI\_GROUP* with the option *NOEU\_ORDO*. This option makes it possible to create an ordered *GROUP\_NO* containing the nodes of one together of meshes made of segments (*SEG2*, *SEG3* or *SEG4*).

An example of extraction of component is given in case-test *SSNL503* (see description with paragraph [§6.2]):

```
TAB_DRZ=POST_RELEVE_T (ACTION=_F (
GROUP_NO = "Of,
ENTITLE = "TB_DRZ",
RESULT = RESUL,
NOM_CHAM = "DEPL",
NOM_CMP = "DRZ",
TOUT_ORDRE = "YES",
OPERATION = "EXTRACTION"
)
)
```

***Document: U2.03.03***

***Note of use of the mean model of hull thermics***

***Summary***

***Determination of the field of temperature in a mean structure subjected to various conditions thermics can be done advantageously using the model of thin hull thermal describes in [R3.11.01]. The temperature is described by three scalar fields, noted TEMP, TEMP\_INF, TEMP\_SUP defined on***

***surface average (X) hull, which will have to be with a grid, and by a distribution in the thickness x3 given by***

***:***  
***T (X, x3) = TEMP (X) P (X***

***(X***

***(X***

***1***

***3) + TEMP\_INF (X) P2***

***3) + TEMP\_SUP (X) P3 3)***

***the functions P***

***and being given. In this model, the curve of the hull does not intervene.***

***1, P2***

***P3***

***One can treat the stationary situations, as well as the problems of evolution. The latter must however to respect a limitation: it is necessary that the moments Tc characteristics of the evolution of the loadings***

***are such as:***

***T > C H2***

***C***

***33***

***with:***

*C: voluminal heat of material constitutive of the hull,*

*H: half thickness of the hull,*

*33: coefficient of transverse conductivity.*

*One gives here the description of the Aster orders useful for calculation, classified by chronological functionalities.*

*1*

*Management of work: grid*

*The process of grid more general of an unspecified surface in IR3 being the triangularisation, one must thus constitute a grid by triangles of the average surface of the hull, plunged in IR3. That can be done with IDEAS and procedure PRE\_IDEAS for the conversion of the universal file*

*IDEAS [U4.13.01].*

*In the case of a plate or of a cylinder, one can use Ali-Baba and procedure PRE\_ALIBABA for the conversion [U4.13.02], which generates a grid plunged in IR3.*

*Example:*

*PRE\_ALIBABA (*

*PLATE*

: /"YES"

/  
"NOT"  
[DEFECT]

**ROLL:**  
(R: ray)

);

*In the case of the cylinder the plane grid (X, Y) of Ali-Baba is transformed into a grid:*

*(X = R cos X, y = R sin X, Z = Y)  
in IR3, where R is the ray.*

R  
R

y  
Y

*: 3/6*

**2**

*Modeling, characteristics, material, loadings*

.  
*To describe for example the materials, the loadings..., one can use constants, functions or of the tablecloths with operators `DEFI_CONSTANTE`, `DEFI_FONCTION` or `DEFI_NAPPE` [U4.21.01, -.02, -.03].*

.  
*To affect the finite elements on the grid, one uses operator `AFFE_MODELE` in the way following:*

***MOD = AFFE\_MODELE (***

***GRID:***

***my***

***[grid]***

***AFFE:***

***(***

***ALL***

***:***

***“YES”***

***PHENOMENON: “THERMAL”***

***MODELING: “HULL”***

***);***

.

*To assign the geometrical characteristics to the elements, in fact the thickness, one must to use operator **AFFE\_CARA\_ELEM** [U4.24.01]:*

*= **AFFE\_CARA\_ELEM** will cara  
(MODEL: MOD  
[model]*

***HULL:**  
(ALL  
:  
"YES"*

***THICK: thick***

*);*

.

*The definition of materials and their assignment with the grid are made in a usual way [U4.23.01 and -.02].*

.

*The assignment of the thermal loadings is done using operators **AFFE\_CHAR\_THER** or*

***AFFE\_CHAR\_THER\_F [U4.25.02]. The various key words usable are:***

***I TEMP\_IMPO***

***: (/NODE***

***: lno***

***/***

***GROUP\_NO***

***: lgn0***

***I TEMP***

***:***

***T1***

### ***The broad outline of calculation thermo-metal-worker-mechanics***

***In Code\_Aster, calculations thermics, metallurgical and mechanical are uncoupled. Stages successive of a complete calculation are as follows:***

***1) One carries out a thermal calculation which makes it possible to obtain the field of temperature in each node.***

***2) One realizes in post treatment of thermal calculation, the metallurgical calculation which makes it possible to obtain proportion of the various metallurgical phases in each node and possibly hardness associated.***

***In Code\_Aster, one can treat two different types of material, which undergo metallurgical transformations: steels or the ZIRCALOY. One is interested here only in materials of the steel type.***

***For a steel, one can take into account five different metallurgical phases: ferrite, pearlite, the bainite, martensite, known as phase, and austenite, known as phase.***

***3) From the field of temperature and metallurgical phases, one carries out mechanical calculation by choosing a model of behavior which takes into account the various possible effects metallurgical transformations. One obtains the stress fields thus, of deformations and of variables intern in each point of Gauss.***

## **2**

### ***That to make to carry out a calculation thermo-metal-worker-mechanics***

#### **2.1**

##### ***Stage 1: which documents lira summarized***

##### ***2.1.1 For the thermal part***

***The document [R5.02.02] contains information necessary to the comprehension of a calculation nonlinear thermics.***

***In Code\_Aster, for a nonlinear calculation, one treats the diffusion of heat with one enthalpic formulation. One can provide is conductivity and the enthalpy according to temperature, is conductivity and the specific heat  $C$   $P$  according to the temperature.***

##### ***2.1.2 For the part models metallurgical behavior***

*The document [R4.04.01] of Code\_Aster describes the various metallurgical models.*

*Brief summary:*

*When a material is heated, the phases are transformed into phase. When it is cooled material, austenite is transformed, according to the speed of cooling, into ferrite and/or pearlite and/or bainite and/or martensite. It is thus necessary to define for the heating the kinetics of transformation and for cooling the nature and the kinetics of the possible transformations.*

*Kinetics of transformation to the heating:*

*The law of evolution of austenite is given by the equation:*

*Z*  
*Z*  
*Z*  
*eq -*  
*& =*

*: 4/14*

*where Z is the proportion of phase,*

1

*Ac the quasi-static temperature of beginning of transformation phases, Ac3 the quasi-static temperature of end of transformation of the phases and 1, 3 two coefficients of material. Z eq corresponds to the evolution of the austenite rate transformed at the time*

*quasi-static evolutions. Initial temperatures*

1

*Ac and of end Ac3 of transformation austenitic and parameters 1 and 3 can be identified starting from experimental data providing for different heating rates, the proportion of austenite formed according to the temperature. One will find in [bib1] precise details on the method of identification of the coefficients.*

*Example:*

*For a steel 16MND5, the coefficients are worth*

1

*Ac = 716°C, Ac3 = 802°C,*

12s

1 =

and

5

.

0 S

3 =

.

*Kinetics of transformation to cooling:*

*For the ferritic, perlitic and bainitic transformations, the kinetics is given by the relation following:*

+

C

T

(- Ms)

$$Z \& = F T$$

(, T&, Z, ms; D)

with  $Z = \{Z F, ZP, ZB\}$

T

(- Ms)

*where M S represents the martensitic initial temperature of transformation, C*

***D size of grain  
austenitic and***

***+***

***(X) the positive part of X. For the functions of evolution F, one does not impose particular forms and the identification of F is summarized with the definition of diagrams of the type TRC***

***(transformation into Continuous Cooling). This diagram makes it possible to define the evolutions of ferrite, pearlite and bainite associated with a thermal history with cooling and conditions of austenitization given (for a size of grain C D given).***

***For the martensitic transformation, one uses the kinetics of Koistinen-Marburger given by the equation:***

***Z  
= 1  
(- Z - Z - Z)  
M  
F  
P  
B [1 - exp ((M  
T) +  
-  
)  
S  
J  
M***

***if Z  
+ Z + Z threshold***

***M =***

***0***

***S***

***S***

***F***

***P***

***B***

***M + Akm (Z + Z + Z) + Bkm***

***if Z***

***+ Z + Z > threshold***

***s0***

***F***

**P**  
**B**  
**F**  
**P**  
**B**

*where  $M_{s0}$  represents the martensitic initial temperature of transformation when that  $C_i$  is total and,  $A_{km}$ ,  $B_{km}$  and threshold are parameters materials.*

*In the simplest case, one can take the temperature  $M_S$  constant and thus equalizes with  $M_{s0}$ . For a steel 16MND6,  $M_{s0}$  is worth 365°C.*

*Note:*

*Diagrams TRC relate to conditions of austenitization given to which correspond a value of size of grain  $D$ . This size of grain results from the history thermics undergone with the heating and does not evolve/move any more with cooling. In Code\_Aster, it is possible to calculate starting from the thermal history with the heating, the evolution of cut grain and to take account of its effect on the metallurgical behavior with cooling (see case test of reference [hsnv126a.com m](#), [hsnv126b.com m](#) and [mtlp102a.com m](#) for the use).*

*Note:*

*It is possible in Code\_Aster to calculate  $H_v$  hardness of the multiphase mixture*

*5*

*given by the Hv relation =  $Z_k H_{vk}$  where  $H_{vk}$  is hardness associated with the phase  $K$  and  $K = 1$*

*informed under operator DEF1\_MATERIAU under key word "DURT\_META". Hardness multiphase mixture is obtained by operator CALC\_ELEM with the option "DURT\_ELNO\_META" (hardness with the nodes by element).*

### *2.1.3 For the part mechanical behavior with effects models of metallurgical transformations*

*The reference document of Code\_Aster is the note [R4.04.02].*

*Several models of behavior are available in the code. They make it possible to model them various following phenomena: plastic behavior or viscous behavior, work hardening isotropic linear or not linear or linear kinematic work hardening, plasticity of transformation, restoration of metallurgical work hardening of origin, restoration of work hardening of viscous origin. One*

*can carry out a calculation in small deformations but also in great deformations (attention them great deformations for a model with kinematic work hardening are not activated). For one comprehension on the aspect great deformations, lire reference documents [R5.03.31] (great deformations without metallurgical effect) and [R4.04.03] (great deformations with effects metallurgical).*

*Brief summary:*

*The effects of structure transformations on the mechanical behavior are of 4 types:*

*.  
the mechanical characteristics of the material which undergoes transformations are modified. In private individual, plastic characteristics (elastic limits in particular) and the coefficient of thermal dilation are strongly affected. For the elastic limit of the multiphase point, one use a non-linear law of the mixtures given by:*

*4*

*Z*

*4*

*4*

*I there I*

*= I*

*[- G (*

*y*

*Z)] + G (*

*I*

*y*

*i=*

**Z)**  
**,**  
**= 1**  
**I**  
**y**  
**ya**

**4**  
**i=1**  
**i=1**  
**Zi**  
**i=1**

*where Zi is the proportion of each phase and G a function of Zi.*

*the expansion or the voluminal contraction which accompanies structure transformations translated by a spherical deformation “of transformation” which is superimposed on thermal deformation. In general, one gathers this effect with that due to the modification of thermal dilation coefficient. The thermal deformation is given by:*

**4**  
**HT**  
**= Z [**  
**R**  
**Tref**  
**T**  
**(- T**

**ref.) - 1**  
**(- Z)**

**+ Z T**  
**(- T**  
**) + Z**

**F**  
**]**  
**I [**  
**R**  
**Tref**  
**F**  
**ref.**

***F***  
***J***  
***i=1***

***where and F are the dilation coefficients of the austenitic and ferritic phases, respectively.***

***Tref***

***F translates the difference in compactness between the two phases with temperature of reference. There are R***

***Z = 1***

***when the phase of reference is the phase austenitic and R***

***Z = 0***

***when the phase of reference is the ferritic phase.***

***.***

***a transformation proceeding under constraints can give rise to a deformation irreversible and this, even for levels of constraints much lower than the elastic limit material. One calls this phenomenon the plasticity of transformation. Into small deformations, this additional term appears in the expression of the total deflection. The law of evolution of the deformation which accompanies this phenomenon writes:***

***4***

**$P_t$**   
 **$\& = 3 \sim K F ($**   
 **$I I Z). Z\&$**

**2**  
**I**  
 **$i=1$**

*where  $\sim$  is the diverter of the tensor of the constraints,  $X$  the positive part of  $X$ ,  $K_i$  and  $I$   $F$ , coefficients of the 4 ferritic phases. It is considered that this phenomenon does not exist at the time austenitic transformations.*

*finally, one can have at the time of the transformation a phenomenon of restoration of work hardening:*

*the work hardening of the mother phase (or not completely) is not transmitted to the phases lately created. The phases lately created can be born with a state of virgin work hardening, either to inherit only part of work hardening of the mother phase or to inherit the totality of the work hardening of the mother phase.*

*In the case of an isotropic work hardening, the plastic deformation  $p$  is not characteristic any more state of work hardening and it is necessary to define other variables for each phase, noted  $K$   $r$ .*

*Isotropic work hardening is written then:*

**4**  
 **$F Z$**   
**4**  
 **$R = 1$**   
 **$(- F (Z))R + ()$**

**$Z. R$**   
**I**  
 **$I, Z = Z$**   
**Z**  
**I**  
 **$i=1$**   
 **$i=1$**

*where  $R_k$  is the variable of work hardening of the phase  $K$  which can be linear or not linear by report/ratio with  $K$*

*$R$  and  $F (Z)$  a function depending on  $Z$  such as  $F (Z) []$*

**I**  
**,**  
**0.**

*The laws of evolution of the ir variables are given by:*

*4*  
*- Z& (R - R)*

*Stage 2: construction of the command file*

*2.2.1 Parts thermics and metallurgical*

*1) Definition of diagram TRC: to see order DEFI\_TRC in the document [U4.43.04].*

*This order is made up of three parts: a part where the ferrite evolutions are defined, pearlite and bainite associated with a unit with thermal history to cooling and conditions of austenitization given (size of grain), one second part which defines them parameters related to the change of temperature ms and a third part which defines the influence of size of grain on the metallurgical transformations with cooling by diagram TRC. This last part is not obligatory.*

*2) Definition of the initial metallurgical phases: to see order CREA\_CHAMP in document [U4.72.04]. This order makes it possible to define the initial metallurgical phases present in material.*

*3) Definition of material: to see order DEFI\_MATERIAU (document [U4.43.01]). For thermal part, it is necessary to inform the key word THER\_NL which contains the values of conductivity thermics and those of the enthalpy, functions possibly of the temperature. For the part metallurgical, it is necessary to inform the key word META\_ACIER of which the structure is as follows:*

*META\_ACIER: (*

*TRC: name of diagram TRC defines into 1)*

*AR3: quasi-static temperature of beginning of decomposition of austenite to cooling.*

*ALPHA: coefficient has law of Koistinen-Marburger*

*MS0: martensitic initial temperature of transformation when this one is total.*

*AC1: quasi-static temperature of beginning of transformation into austenite with the heating.*

*AC3: quasi-static temperature of end of transformation into austenite.*

*TAUX\_1: parameter intervening in the kinetics with the heating.*

*TAUX\_3: parameter intervening in the kinetics with the heating.*

*LAMBDA: parameter material intervening in the model of evolution of size of grain.*

*QSR\_K: parameter energy of activation intervening in the model of evolution of size of grain.*

*DI0: parameter material intervening in the model of evolution of size of grain.*

*WSR\_K: parameter energy of activation intervening in the model of evolution of size of grain.*

*4) Realization of thermal calculation: to see documentation of Use and Reference of thermal operators: THER\_LINEAIRE and THER\_NON\_LINE.*

*5) Realization of metallurgical calculation: to see order CALC\_META (document [U4.85.01]). This order makes it possible to obtain starting from preceding thermal calculation, the proportions of various metallurgical phases. It is on this level that the initial metallurgical state is informed (order CREA\_CHAMP).*

## **2.2.2 Part mechanics**

### **1) Definition**

***material: to see order DEF1\_MATERIAU (document [U4.43.01]). According to phenomena which one wishes to model, several key words must be indicated. In all the cases, the user must supplement the key words:***

•  
***ELAS\_META (\_FO) which contains information on the elastic characteristics, of thermal dilations and of elastic limits,***

•  
***META\_ECRO\_LINE to define an isotropic or kinematic work hardening linear and META\_TRACTION to define a nonlinear isotropic work hardening.***

***Instruction manual***

***U2.03 booklet: Thermomechanical***

***HT-62/06/004/A***

**V. CANO** Key

:

U2.03.04-B Page

: 9/14

*The other possible phenomena (nonobligatory) are as follows:*

.  
*viscoplasticity + restoration of viscous origin: key word factor META\_VISC (\_FO)*

.  
*plasticity of transformation: key word factor META\_PT*

.  
*metallurgical restoration of origin: key word factor META\_RE*

**Note:**

*\_FO means that the coefficients can possibly depend on the temperature.*

**2) Realization of mechanical calculation:** order STAT\_NON\_LINE (document [U4.51.03]). Under key word COMP\_INCR, one must specify under RELATION, the name of the model chosen among the 24 models below and under RELATION\_KIT, material "STEEL".

*The various models are:*

*/“META\_P\_IL”*

*/“META\_P\_INL”*

*/“META\_P\_IL\_PT”*

*/“META\_P\_INL\_PT”*

*/“META\_P\_IL\_RE”*

*/“META\_P\_INL\_RE”*

*/“META\_P\_IL\_PT\_RE”*

*/“META\_P\_INL\_PT\_RE”*

*/“META\_P\_CL”*

*/“META\_P\_CL\_PT”*

/"META\_P\_CL\_RE"  
 /"META\_P\_CL\_PT\_RE"  
 /"META\_V\_IL"  
 /"META\_V\_INL"  
 /"META\_V\_IL\_PT"  
 /"META\_V\_INL\_PT"  
 /"META\_V\_IL\_RE"  
 /"META\_V\_INL\_RE"  
 /"META\_V\_IL\_PT\_RE"  
 /"META\_V\_INL\_PT\_RE"  
 /"META\_V\_CL"  
 /"META\_V\_CL\_PT"  
 /"META\_V\_CL\_RE"  
 /"META\_V\_CL\_PT\_RE"

### ***Significance of the letters:***

*P = plasticity, V = viscoplasticity, IT = linear isotropic work hardening, INL = work hardening isotropic nonlinear, linear CL = kinematic work hardening, Pt = plasticity of transformation, RE = restoration of metallurgical work hardening of origin.*

### ***2.2.3 Example of command file***

*The example that we present now is that of a thin steel 16MND5 disc which is heated on its face higher by a laser beam then cooled than the ambient air. Modeling is axisymmetric. The imposed loading is a flow on part of the higher face, the remainder of faces undergoing of the conditions of natural convection and radiation. Initially the disc is composed of 61% of ferrite and bainite 39%. With the heating, ferrite and the bainite change into austenite. With cooling, austenite is transformed into bainite and martensite (it thus does not have there pearlite). This study is presented in detail in document HI-74/99/002.*

*One presents Ci below the command file of this simulation. One gives only them principal orders which refer to a metallurgical calculation.*

***Thermal modeling of welding***

### ***1.1 General***

***The modeling of an operation of welding requires the good knowledge of the process with to simulate, in particular that of the parameters of welding. Moreover, phenomena to be taken in account are many and complex: contribution of the molten metal, flow generated by the arc unit + electrode, effect of gas protecting the bath melted, etc...***

***The principal difficulty of the thermal modeling of welding is the way in which one takes into account the contribution of heat. In front of the great number of operational data accessible (energy from welding, speed of the source, tape speed of the wire of contribution, output of the process...), it is necessary***

***in general to adopt a simplified method. These methods will be described in the § according to. simulations carried out within the framework of a collaboratif work EDF-ECA-Framatome [bib1] showed***

***that other phenomena concerned (heat exchange, change of state, convection of the bath melted...) are suitably taken into account by the computer codes by finite elements.***

***In the case which we present in the continuation, one has at the same time a good knowledge of parameters of welding and elements of retiming like macrographies and the cycles***

*thermics. A correct thermal simulation is thus possible. The problem is then to choose a method which will make it possible to represent accurately the contribution of heat due to the Arc unit -*

*Electrode - Filler.*

*If one does not have elements of retiming, the digital simulation of an operation of welding can be carried out in a predictive way using calculations simplified of Rosenthal type. For more details, one will consult [bib1]*

## **1.2**

### **Modeling of the contribution of heat**

*Two methods are possible:*

*.  
the first consists in imposing cycles of temperature on the matter which one deposits. These imposed temperatures can be applied either to the only cord deposited, or on the cord unit deposited more molten zone. This method applies easily only to two-dimensional problems. If one imposes a temperature in the filler, it calculation proceeds in 3 phases:*

- 1) Temperature imposed in the cord deposited until a temperature of molten bath higher than the melting point.*
- 2) Maintenance of the constant temperature during a time characteristic and increase of thermal conductivity for temperatures higher than the melting point so to find the molten zone.*
- 3) Cooling with exchange by convection and radiation*

*The thermal cycle applied to the filler can result either from a calculation 3D or in using calculations of the Rosenthal type to determine the maintenance and boarding times.*

*.  
the second method, which is that recommended now, consists in imposing a heat flow on weld bead modelled. It can this time apply in 2D and 3D and present the advantage of modelling only the filler (it is not necessary to know the zone melted). On the other hand, it is difficult to fix but the choices are to be carried out on the space distribution*

*flow (surface, voluminal) and the temporal distribution of flow.*

*The chock of flow can be controlled on the basis of calculations 2D of the Rosenthal type or by using them*

*experimental thermal cycles. In order to find the molten zone and to take account of the homogenisation of the temperature due to the movements of the bath melted, one increases beyond*

*melting point of a factor 100 thermal conductivity in the added metal.*

**Case of a piping welded by pulsated process TIG (card 3488)**

***Here one knows a priori the form of the cords and the zones melted thanks to macrographies. It is nevertheless difficult to use the method No 1 (approach in imposed temperature) insofar as the chamfer contains 13 welding layers. To model the molten zones associated with the 13 cords would have asked too much work in term of grid. This method is applicable only if the number cords remains limited or if macro deposits are considered.***

***The other methods were tested but require all of the chocks with the results experimental and give unequal results. Thus, approach in imposed temperature considering the contribution of heat that in the filler over-estimates the molten zones and the cycles thermics. This method is too calorific.***

***It is thus the approach in imposed heat flux which is retained. The application of the quantity of heat  $Q_r$  presents two alternatives: the application of surface or voluminal  $Q_r$ . If one is considered axisymmetric model of piping, the quantity of  $Q_r$  heat is applied in all the meshes modelled cord and one represent a flow 3D thus. In the case of a model 3D, it is difficult of to consider voluminal  $Q_r$  because one precisely does not know the form of the heat source. It is thus surface  $Q_r$  on the free edge of the cord that it is to better retain. However,  $Q_r$  surface is representative only if the cords deposited are not too thick, which is the case here.***

**1.3.1 Methodology: choice of an approach 2D or 3D**

***In any rigour, the process of welding is strictly 3D, the contribution of heat and possibly of***

*matter being mobile and constant speed. Numerical calculations should thus hold account of it. However, complex and expensive calculations 3D being, they are seldom implemented and one limits oneself*

*with the 2D. Modeling 2D implies an important simplification: one neglects the effect speed of welding and one suppose that the cord is deposited simultaneously over the entire length of the chamfer.*

*However, in order to carry out the chock of the yield coefficient of the process, calculations 3D in locate mobile were also led for 2 master keys of the chamfer: the master key of root and one pass current (master key 13).*

*The chock of master key 13 was then applied to all the other current passes.*

*The methodology retained for the thermal simulation of pulsated process TIG is thus the following one:*

*• chock of the yield coefficient of the process for master keys 1 to 13 thanks to calculations 3D in pointer on master keys 1 and 13,*

*• transposition with the model 2D by preserving the yield coefficient and by applying one quantity of heat to the meshes of the modelled cord. The temporal distribution this flow is fixed on the results of calculations 3D,*

*• validation of this approach to the thermal simulation of master keys 2 to 13.*

### *1.3.2 Approach thermal 3D in pointer on the plate 3D developed of the tube*

*The chock of the method is done on the transverse form of the zone melted by adjusting the coefficient*

*of output of the process. Several iterative calculations make it possible to have an acceptable molten zone.*

*For the master key of root, the yield coefficient is worth 0.65 then.*

*UI*

*The quantity of heat applied is worth  $Q_r =$   
with:*

*S*

*• U, the voltage welding taken equalizes with 11V,*

*• I, the intensity of welding taken equalizes with 200A,*

*• S, the surface of the source which is worth R2 with R=5mm.*

### **1.3.3 Approach thermal 2D on the tube**

*The axisymmetric approach 2D is easy to implement but presents the disadvantage of not to take into account the effect speed and to consider that each cord is deposited “of only one blow”. Comparisons between approaches 2D and 3D [bib3] nevertheless showed the maid representativeness of the approach 2D.*

#### **1.3.3.1 Temperatures**

***imposed***

*This method is the first method described in [§2.2]. The contribution of heat is modelled by one cycle thermal resulting from calculation in pointer. This cycle is applied to the nodes of the added metal. It is noted that calculations 2D over-estimate the molten zone and maximum thermal cycles. The approach in imposed temperatures is thus too energy.*

***1.3.3.2 Heat flow***

*This method is the second method described in [§2.2] and is that recommended now. The application of the heat flow  $Q_r$  is carried out on the meshes of the cord deposited. This heat flow is voluminal, c.a.d. per circumferential unit of length ( $J/mm^3$ ). Flow is given by:*

*UI*  
 $Q_r =$   
*with v: speed of the source.*  
 $Sv$

*Calculation 2D disregarding speed of the source, it is necessary to distribute this heat flow in function of time: a descent and maintenance, boarding time.*

### **1.3.4 Conclusion**

*Within the framework of the thermal simulation of welding by pulsed process TIG of a piping in stainless steel 316L, the thermal history of the process can be represented by a model 2D axisymmetric, even if retiming is better by considering an approach 3D in pointer which account of the effect speed of the heat source takes. The methodology retained in 2D is one approach in heat flow which requires to fix the yield coefficient of the process as well as temporal distribution this flow. It is also necessary to know either the forms of the melted zones, or thermal cycles of the process studied in order to allow this chock. It makes it possible not to model melted zones, which is an important advantage in the case of a great number of master keys.*

*The principal characteristics of simulation are as follows:*

- .  
heat flow applied in the metal added according to time (gone up in 7s, times of maintenance of 5.8s for the master key of root and 3.4s for a current master key and descent in 1s),*
- .  
the yield coefficient of the process is fixed at = 0 6  
. 5 for the master key of root and with  
= 05  
. 5 for the current master keys,*
- .  
the conductivity of the added metal is increased between 1500°C and 1700°C of a factor 100 so to take into account a homogenisation of the temperatures in the bath melted,*
- .  
one takes into account the heat of fusion-solidification,*
- .  
the thermal characteristics vary with the temperature.*

## **2** **Modeling of welding in Aster**

### **2.1** **Grid of the weld beads**

*The weld beads can be with a grid in a more or less complex way.*

*There are 3 possible choices, while going from most complicated towards simplest:*

.

*one can choose to respect at the same time the volume and the form of the master key. The shape of the cords*

*being curved, one will have to net surfaces on curved board, therefore to use finite elements at least of degree 2,*

.

*one respects only the volume of the master key, the cords being of triangular form or quadrangular. In this case, one can use linear elements,*

.

*the weld beads are quadrangular, while trying to respect volume as well as possible of each master key.*

*Comparisons were made in the case of the tubular model. It proves that the results of mechanical calculations differ very little from one grid to another. Nevertheless, the comparison with coarser grid is delicate, thermal being different to it.*

*One can however note that, to thermics equivalent, the curved grid does not bring anything significant on the level of the results compared to the polygonal grid.*

### **2.2 Calculation** **thermics**

#### **2.2.1 Modelings associated with the master keys**

*To simulate welding multirun, one carries out a transitory nonlinear thermal calculation, passes by master key, by adding to each master key in the thermal model corresponding the finite elements modelling the weld bead deposited during the master key. Thus, each master key I has one thermal model including/understanding the weld beads of numbers 1 to I. There are thus models thermics encased with the following direction:*

*if mothi indicates the thermal model of master key I  
and mothj indicates the thermal model of the master key J  
then mothi mothj if  $I < J$ .*

*This poses a problem at the time of the sequence of thermal calculations, the fields of temperature of model mothi not being defined in all the nodes of the model corresponding to the following master key  $i + 1$ .*

*It is thus necessary to carry out a prolongation of the computed fields from one model to another. (see [§3.2.3]).*

**Note:**

*Another solution consists in considering one model containing all the passes and “artificially to decontaminate” the cords not yet deposited in their imposing one null thermal conductivity. This artifice can cause light numerical oscillations temperature due to the discontinuity of conductivity to the interfaces between the cords. It is nevertheless this method which is used in the cast-test [V7.42.100]. It allows to save the stage of prolongation of the fields [§2.2.3].*

*: 8/12*

## **2.2.2 Boundary conditions (convection and radiation)**

*For the modeling of the convectif and radiative exchange, one chose to make appear:*

.

during the rise and the maintenance of  $Q_r$ : convective and radiative exchange on all the borders except that of the cord of the current master key,

during cooling: same boundary conditions with in more the border of the cord current master key (to take into account the weld bead have been just deposited).

The figures of boundary conditions (meshes of edge support of the boundary conditions) are with to reactualize with each master key on the level of the chamfer, cords piling up the ones on the others. It is necessary to have envisaged this operation upon the departure, at the moment it grid, i.e. to have created as many figures as there are master keys.

### 2.2.3 Prolongation of the fields

The prolongation of the fields of temperature (and possibly of metallurgy) is necessary to end of each master key so that those are defined on the model of the following master key. One proceeds in

4 stages:

one starts by creating a field of temperature to ambient ( $T_{20}$ ) on all the grid by order CREA\_CHAMP (operation "AFFE"),

one extends the first field of temperature calculated to master key I (sequence number 1) in supplementing by  $T_{20}$  on new meshes (CREA\_CHAMP operations "EXTR" then "ADZE"),

one stores this field in a new structure of data of the evol\_ther type by order CREA\_RESU,

one makes a loop on the remaining sequence numbers and one repeats operations 2 and 3 for each sequence number by enriching the structure of data created in 3 (key words reuse of CREA\_RESU).

Example:

```
#EVOTH1: EVOL_THER ON MODEL MOTH1 KNOWN EAST
#ON WANTS TO CALCULATE EVOTH2 ON "A LARGER" MODEL MOTH2 THAN MOTH1.
#LES 2 MODELS ARE BASED ON the SAME GRID EMAIL

## 2.3

### **Mechanical calculation**

#### **2.3.1 Modelings associated with the master keys**

**Contrary to thermal calculations, it is advised to use the same mechanical model for all passes. This model will include/understand all the cords, the cords not deposited being decontaminated artificially in their affecting a very weak Young modulus ( $E =$**

**-**  
**10 the 11th reality in**

**practical). The interest of such a technique is that the soft cords become deformed with the chamfer, allowing to take again the following master key on the geometry deformed without having mending of meshes to make.**

**It should nevertheless be taken care that the not activated cords preserve a realistic form during calculations. If it is not the case, they should be re-meshed.**

**For the cord deposited, the real mechanical characteristics are imposed to him when this one has reached the melting point. Thus, in the phase of heating, the cord is still fictitious.**

**This technique is preferable with that consisting in duplicating all the nodes of the interfaces of cords and to impose connections in increment of displacement between ddl. Indeed, the latter technique, even if it reproduces reality rather accurately, has as a disadvantage of involving whimsical deformations, cords not being attached to the structure at the beginning of each master key. Of**

**more, the setting in data of the connections is heavy and their expensive taking into account in time CPU.**

#### **2.3.2 Fastening of the welded zone**

**The axisymmetric modeling of welding on a tube supposes implicitly wrongly that welding has place simultaneously on all the circumference of the tube, therefore that the temperature rises everywhere in**

**chamfer. In reality, the heat source progresses towards part of structure remained cold, who attaches obligatorily the welded zone. The part, on the level of the heat source, thus cannot to dilate freely. This effect of autobridage must grow blurred when diffuse heat and disappear with run of the phase of cooling.**

**To cure this problem, one can force an axial fastening on the tube, only in the phase of heating. One thus prevents the tube from freely dilating with the heating, on the other hand it is free to deform with cooling.**

**Instruction manual**

**X. DESROCHES Key**

**:**

**U2.03.05-A Page**

**: 10/12**

**The implementation in Aster is done in the following way:**

•  
**one models the supports by elements of edge (segments) which one blocks them displacements. These elements have nodes confused geometrically with the nodes in with respect to the border of the tube,**

•  
**one puts in contact the supports and the elements of edge of the border (key word CONTACT of AFFE\_CHAR\_MECA),**

•  
**at the end of each master key, when the geometry is reactualized, i.e. one replaces initial geometry by the deformed geometry, these fictitious supports also should be reactualized by repositioning them on the deformed border, as the 3 diagrams show it below:**

**initial supports  
chamfer**

**deformed after master key 1**

**reactualized supports**

**2.3.3 Mechanical calculation of a master key**

*The mechanical model used is that which can take into account the effects of the transformations metallurgical. The law of behavior used is élasto-visco-plastic. The model is isotropic with a function threshold of the Von Mises type and a nonlinear isotropic work hardening with restoration viscous of work hardening. One does not take account of the phenomena of plasticity of transformation and of metallurgical restoration of work hardening (law of behavior META\_VNL in Aster). The effect kinematic work hardening was not looked at but it can be taken into account. The increments of deformations used for the incremental relation of behavior are them linearized deformations of the increment of displacement in the reactualized geometry (large displacements, small deformations). It is option PETIT\_REAC of STAT\_NON\_LINE (the large ones deformations are possible but are generally not necessary)*

*The convergence of the method of Newton is difficult at the beginning of cooling and it is necessary to use the linear algorithm of research to improve convergence. (key word RECH\_LINEAIRE STAT\_NON\_LINE by using the default values).*

*At the end of each master key, one reactualizes the grid, i.e. one replaces the initial grid by deformed geometry. (operator MODI\_MAILLAGE key word factor DEFORMS) and they are reactualized supports.*

*The treatment of the plastic incompressibility poses problem by generating oscillations of important constraints, in particular of the trace. The use of under-integrated elements QUAD8 does not have not made it possible to solve the problem because the grids comprise many elements TRIA6 in the plasticized zones for which one did not have a version under not integrated. One recommends to use them new incompressible elements (modelings PLAN\_INCO, AXIS\_INCO and 3D\_INCO), which have given promising results from this point of view. These elements will be available in version 6.3 of Aster.*

### **3 Conclusion**

***The digital simulation of a test of welding on tube on the 13 ways made it possible to release one method for calculation whose principal points can be summarized as follows:***

***grid: each cord must be with a grid by a group of meshes. It is not necessary to have a very precise representation of the shape of the cords. On the other hand, the respect of volume and of the position of the cord in the chamfer is important.***

***thermics: the modeling of the contribution of heat is the essential point. Method recommended consists in imposing a heat flow on the meshes of the cords deposited. This flow is constant spaces some and function of time. To determine the temporal dependence, it is necessary to proceed to a thermal retiming starting from experimental data (evolutions of temperature, zones molten) or in the absence of data on the process of welding and of simplified calculations.***

***thermal retiming has an important effect on the final mechanical results, them deformations and residual stresses being sensitive as much to the value that with distribution of the heat source.***

***mechanics: in the case of a high number of master keys, the displacements cumulated in chamfer are important and it is preferable to make a calculation in great displacements with reactualization of the grid at the end of each master key. The assumption of the great deformations is on the other hand not necessary.***

***in the case of a tube, the axisymmetric modeling of welding requires the catch in account of boundary conditions particular, more precisely axial fastening zone welded to take into account the fact that the torch progresses towards one part of structure remained cold. This fastening is essential to obtain correct values of the contracting of the chamfer.***

***modeling Aster: one recommends to build encased thermal models container that cords actually deposited and to prolong the computed fields of one***

*model with the other. On the other hand, it is preferable to have only one mechanical model comprising the totality of the cords upon the departure, cords being decontaminated artificially in their affecting a Young modulus quasi-no one. In this way, one avoids having to re-mesh them weld beads as the chamfer becomes deformed.*

## ***Realization of a study civil engineering with cables of prestressing***

### ***Summary:***

***The purpose of this document is to give councils to make concrete studies reinforced with cables of prestressed. It gives information on the precautions of grid, on the methods of application of prestressed and on the possibilities of phasage.***

### ***1 Introduction***

***The studies of Civil Engineering are often rather complex to carry out insofar as they make to intervene of modelings 3D, hulls, bars and several materials. This document tests mutualiser the experience gained on the subject by giving councils of methodology for the grid and the phase of modeling, concerning the prestressed structures.***

***Implementation the numerical of the tension requires some precautions of use, in particular in case of non-linear calculations, since the chronology of the loadings can impact the results. In this document we see how to set up the orders ASTER to reproduce some examples of possible situations in reality.***

### ***2 Remark preliminary***

*In Code\_Aster, the cables of prestressing are modelled by elements 1D (bars with 2 nodes). Their setting in tension is possible and consists in applying a nonnull tension in these cables. Two alternatives exist to carry out this setting in tension. First method (available in Code\_Aster since the v5) consists in setting up the conditions kinematics between the cable and it concrete, to calculate the tension along the cable and then to apply these loadings to the model (instantaneous loading) to seek the balance of the structure. Its disadvantage is that the tension who results from balance is generally weaker than that requested by the user.*

*The second method, developed in v7, is an improvement of the first: it guarantees that tension with balance is exactly that required, but also allows the setting in tension successive of the cables to recreate the phasage setting in prestressed structure. The last interest of this method it is the possibility of applying the tension of the cable in a gradual way, which can be necessary for behaviors of the nonlinéaire type, in particular in the event of cracking of concrete during the phase of setting in prestressing.*

*In both cases, the basic ingredients are the same ones (operator `DEFI_CABLE_BP` and `AFFE_CHAR_MECA`). The difference comes owing to the fact that in the first case, the setting in balance is made simply by a `STAT_NON_LINE` whereas in the second case, one uses the macro-order `CALC_PRECONT` which includes a certain number of handling of the model to ensure the setting in tension (cf [R7.01.02]).*

3

*First stage: grid*

*To carry out a calculation on a structure of civil engineering, it is necessary to net the concrete, and possibly reinforcements as well as the cables of prestressing.*

- The grid of the concrete can be carried out with any voluminal element in 3D or in 2D. The elements can be linear or quadratic. If cables of prestressing are also envisaged with the grid then there are some restrictions on the choice of the elements of concrete according to the type of resolution (see paragraph [§4.2] and Notices paragraph [§5]).*
- The reinforcements are obligatorily with a grid with `SEG2` whose nodes must be confused with those of the concrete. It thus should be thought of it when the concrete is netted. In addition, it is necessary to be vigilant if the concrete is with a grid with cubic elements in order to make well to correspond all the nodes concrete located along the reinforcement with a node steel: in other words if the concrete is with a grid with quadratic elements, at the place where must pass a reinforcement, it is necessary to define 2 `SEG2` steel for a mesh concrete.*

: 3/14

· *The cables of prestressed must be with a grid with SEG2. On the other hand, it is not necessary to make coincide nodes of the cable and the nodes concrete: the order DEFI\_CABLE\_BP indeed makes it possible to also create connections kinematics which will bind nodes of the cable with the nodes of the concrete of the surrounding mesh. On the other hand, that generate a great number of multipliers of Lagrange which will weigh down calculation. There is thus a compromise to find between facility to carry out the grid and cost of calculation.*

· *In order to be able to define the cables, it is necessary to have named the nodes of anchoring with each end of the cable.*

**4**

## ***Second stage: the setting in fact of the case***

*One details here the various stages of the setting in data of a standard prestressed concrete problem in Code\_Aster. For each phase, one specifies the possible questions to be posed and them information which should be provided. An example of application is proposed in appendix where one gives various alternatives for the phase of resolution.*

**4.1**

### ***Reading and possible enrichments of the grid***

*To check that the nodes of anchoring are quite accessible (individually) by a GROUP\_NO.*

*To create the possible groups of nodes or meshes for postprocessing.*

*To direct the groups of meshes correctly where one imposes loadings of the pressure type or flow (order ORIE\_PEAU\_3D (2D)).*

### ***4.2 Assignment***

***of one***

***model***

*At present, the reinforcements and the cables of prestressed can be modelled only by elements BARS (resting on SEG2). For the concrete, the choice is much freer, in revenge it is necessary to note the following limitations:*

*In the presence of cable of prestressing, the use of DEFI\_CABLE\_BP authorizes only the elements voluminal or modeling DKT. In addition, the operator CALC\_PRECONT who allows in particular not to put all the cables in tension simultaneously is compatible only with the elements voluminal.*

### **4.3** **Characteristics of the elements of structure**

*To define the section of the passive reinforcements and the cables of prestressing.*

### **4.4** **Definition of materials**

*Laws of behavior available for the concrete:*

- *ELAS,*
- *MAZARS local or not-local version [R7.01.08]*
- *ENDO\_ISOT\_BETON or not local local version [R7.01.04]*
- *BETON\_DOUBLE\_DP [R7.01.03]*
- *KIT\_DDI to combine a mechanical model with the models of creep: GRANGER\_FP, GRANGER\_FP\_V, [R7.01.01], BAZANT\_FD [R7.01.05]*

#### **Note:**

*Model LABORD\_ID [R7.01.07] is available only for the multifibre elements beams POU\_D\_EM thus incompatible for a use with cables of prestressing.*

*Instruction manual*

*U2.03 booklet: Thermomechanical*

*Author (S):*

**S. MICHEL-PONNELLE, J. EL-GHARIB, Key S. GHAVAMIAN: U2.03.06-A Page**

: 4/14

*Laws of behavior available for steels: about all the laws are usable with elements bars, most usually used are:*

- *ELAS*
- *VMIS\_CINE\_LINE* (plasticity with linear kinematic work hardening)
- *PINTO\_MENEGOTTO*
- *VMIS\_ISOT\_LINE* (plasticity with linear isotropic work hardening)
- *VMIS\_ISOT\_TRAC* (plasticity with isotropic work hardening given by a traction diagram)

*The choice of the law determines the key words to inform under `DEFI_MATERIAU`.*

*In the presence of cables and to be able to use `DEFI_CABLE_BP`, it is also necessary to have informed:*

- *key words `BETON_BPEL` (`PERT_FLUA`, `PERT_RETR`) for the meshes concrete,*
- *key words `ELAS` and `ACIER_BPEL` (`SY`, `FROT_LINE`, `FROT_COURB`, `MU0_RELAX`, `RELAX_1000`) for the steel of the cables of prestressing.*

*All these parameters are not obligatory.*

#### **Note:**

- *Parameter `SY` requires a detailed attention since as opposed to what one could wait, it does not intervene in a possible nonlinear calculation with plasticity cables. The `SY` indicated under `ACIER_BPEL` corresponds to the `Fprg` parameter indicated in the payment `BPEL` and which makes it possible to calculate the loss by relieving. To allow a calculation with plasticization, it is necessary to declare the elastic limit with the law of behavior selected.*
- *Order `DEFI_CABLE_BP` cannot consider the case where characteristics rubber bands of the concrete crossed by the cable can vary with the temperature.*
- *Order `DEFI_CABLE_BP` cannot support the case where several materials concrete are traversed by the same cable.*

## **4.5**

### **Definition of the cables**

*The phase of definition of the cables places by order `DEFI_CABLE_BP`. That makes it possible to define which must be the tension in the cables according to rules' of the `BPEL`, according to the initial tension, retreat of anchoring (which applies only for active anchorings), of the relieving of steel and deformations differed from the concrete (creep and withdrawal).*

*Let us announce that only one `DEFI_CABLE_BP` can gather several cables provided that they have them same parameters of entry for the calculation of the tension, and which one wishes to tighten all these*

*cables  
at the same time.*

*The punching created by anchorings can some times give place to numerical difficulties of modeling. The origin of this problem is related to the incompatibility of the load pattern (a force specific created by anchoring) compared to the grid of the concrete (2D or 3D). To avoid this problem, it*

*key word CONE under DEFI\_CABLE\_BP (available starting from the v7 of Code\_Aster) makes it possible to define one*

*volume representing the cone of fainding placed at the end of the cables, and thus to distribute force punching on a volume of the concrete, and either on one or, some nodes at the maximum. geometry of this volume corresponds to a cylinder whose dimensions (length and ray) would have to correspond to the cone of fainding really employed. However it should be noted that if it grid of the concrete in this area is not sufficiently fine, the volume of the cone will not be able to integrate concrete nodes moreover. But under this condition the problem of concentration of constraint will be probably unimportant.*

**S. MICHEL-PONNELLE, J. EL-GHARIB, Key S. GHAVAMIAN: U2.03.06-A Page**

**: 5/14**

**Note:**

- Each end of cable can be declared as being “active” or “passive”. If one cable comprises any active end, no tension is not then applied.*
- The use of the option **CONE** requires a detailed attention as for the way of imposing boundary conditions under penalty of seeing appearing conditions kinematics superabundant which prevents the resolution of the problem.*

**4.6**

**Definition of the loadings**

*It is necessary to define separately (either as many calls to AFFE\_CHAR\_MECA (\_F)) loadings following:*

- Boundary conditions as well as the possible valid instantaneous loadings as of beginning of calculation*
- The relations kinematics making it possible to connect the nodes cables with the nodes concrete: RELA\_CINE\_BP=\_F (RELA\_CINE=' OUI'). This loading is necessary for any calculation with STAT\_NON\_LINE on the model containing the cables of prestressed (if not fatal error for cause of matrix not factorisable).  
During the call to CALC\_PRECONT, the connections kinematics are inutiles\* except when one carry out the setting in tension in several stages. The connections should indeed be included kinematics for the cables which were already put in tension by a first CALC\_PRECONT: that thus relates to the cables which enter neither key word CABLE\_BP nor in the key word CABLE\_BP\_INACTIF (cf example in appendix and more particularly scenario 1). In it case, it is necessary to think of defining as much loading than of phases of setting in tension different.*
- Posterior loadings with the setting in tension of the cables.*

**\* Caution:**

*When the nodes of cable and concrete are not confused (presence of relations kinematics, RELA\_CINE=' OUI') this generates an error. It thus should be avoided in this case.*

## 5

***The resolution of the mechanical problem***

*It is a question here of specifying the loading to be included (key word EXCIT) at the time of the call to CALC\_PRECONT.*

*Several cases arise.*

*1) The user wishes to thus put in tension simultaneously all the cables of prestressed that an instantaneous loading, without other loadings as a preliminary. In this case, it is enough to call upon macro-order CALC\_PRECONT only once. The loading is made up boundary conditions and possible instantaneous loadings. Under key word CABLE\_BP, all concepts DEFI\_CABLE\_BP will be included (see scenario 3 in appendix).*

*2) The user wishes to make calculations before the setting in tension of the cables. In this case, it is appropriate:*

- is not to include the cables in the model used to make calculations before the setting in tension of the cables*

- is to use under key word COMP\_INCR of STAT\_NON\_LINE, the law of behavior RELATION=' SANS' for the meshes of the cable. In this case, it is essential to add in the loadings, the relations kinematics binding cable and concrete (obtained while writing AFFE\_CHAR\_MECA (RELA\_CINE\_BP=\_F (RELA\_CINE=' OUI')) (see scenario 1 and 3 in appendix).*

*3) The user wishes successively to put in tension the cables. In this case, it is necessary to appeal with CALC\_PRECONT as many time as necessary. CABLE\_BP will contain the concepts DEFI\_CABLE\_BP associated with the cables which one is tending during this call to CALC\_PRECONT, CABLE\_BP\_INACTIF will contain those which one wishes to tighten later on: in this way, it is the macro-order which is given the responsibility to affect a law of behavior WITHOUT with these cables and to include the connections kinematics associated with these same cables. For the loading, it is a question systematically of including the boundary conditions as well as possible instantaneous loadings. From the second call to CALC\_PRECONT, it is appropriate to include moreover, the connections kinematics related to the cables already put in tension at the stages the preceding ones (see scenario 1 in Appendix).*

*In all the cases of figure, for the STAT\_NON\_LINE which follow the setting in tension of the cables, it is important not to forget the whole of the connections kinematics related to the cables*

***Note:***

*For the moment, the use of macro-order CALC\_PRECONT is not compatible with the use of hulls to represent the concrete surrounding the cables. It is thus necessary to have recourse to the old method of setting in tension of the cables in spite of its disadvantages [R7.01.02]. The setting in tension is carried out simply while including in loads concept AFFE\_CHAR\_MECA defined by RELA\_CINE\_BP = F (RELA\_CINE = "YES",*

**SIGM\_BPEL=' OUI')**. With the exit of this calculation, the tension in the cables is not equal any more to those prescribed by the BPEL, it is thus necessary to determine the coefficients of correction to apply with the initial tensions applied to the cables (on the level of the declaration of the operator **DEFI\_CABLE\_BP**) allowing to compensate for the loss by instantaneous strain of structure. Once the command file modified by these coefficients of correction, modeling of the cables of prestressing is accomplished.

Attention, in the case of sequence of **STAT\_NON\_LINE**, it is appropriate starting from the second call, to include in the loading only the relations kinematics and not the tension in cables, under penalty of adding this tension, with each calculation (see scenario 2 in appendix). That thus requires to create a second **AFFE\_CHAR\_MECA** with the operand **RELA\_CINE\_BP = F (RELA\_CINE = "YES", SIGM\_BPEL=' NON')** (cf scenario 2 in Appendix).

## **6 Appendix**

**Here an example of application inspired of the case test [V6.04.164] (SSNV164). It is about a crossed post by 5 cables, and the loading is composed of:**

- 1) gravity**
- 2) prestressing in the cables**
- 3) a pressure on the higher face**

**The setting in data is common, then one shows 3 scenarios to solve the problem:**

***The first scenario is most physical:***

- 1) taken into account of gravity***
- 2) put in tension of cables 1 and 2***
- 3) put in tension of cables 3 and 4***
- 4) put in tension of cable 5***
- 5) pressurization***

***The second scenario is that which one applied before the development of the operator CALC\_PRECONT (to version 6 of Code\_Aster) and which is the method which remains recommended in case where one uses a model DKT for the concrete***

- 1) taken into account of gravity and setting in tension of the 5 cables***
- 2) pressurization***

***The third scenario is identical to the second with regard to the order of application of loadings but it uses operator CALC\_PRECONT and thus makes it possible to have directly the tension lawful in the cables of prestressing***

## **1 Introduction**

*One speaks about study of contact as soon as there can be interaction of contact during calculation. It is possible to model the problems of contact-impact and contact-friction with Code\_Aster, into small or great displacements.*

*This document reviews the various methods available, underlines the encountered difficulties and gives councils of use. One will privilege the treatment of the contact by the loads of contact. It exist other methods, they relate to only the specific contact and they are presented in chapter 6.*

### **General step**

*The contact is declared in AFFE\_CHAR\_MECA, like a load. All conditions of contact must be declared in the same AFFE\_CHAR\_MECA (each one in an occurrence of the key word CONTACT).*

*Initially, one indicates surfaces between which one wants to treat the contact.*

*One then chooses to treat the contact with or without friction. In the case of the contact with friction, it is necessary to give the coefficient of friction.*

*One also indicates the methods of calculation to be used and the method of pairing.*

*It is through these stages that one defines all the parameters of the contact.*

*They take place in operator AFFE\_CHAR\_MECA.*

*The conditions of contact are thus declared like a load. They are used like such*

*(key word EXCIT) in the operators mechanics STAT\_NON\_LINE or DYNA\_NON\_LINE.*

*Once completed calculation, one can make a postprocessing of the efforts of contact.*

### **Useful readings**

*Documentation here presents has the role to guide the user at the time of a modeling in contact friction. It takes again the essential indications and gives councils of use.*

*It does not replace the reading of U4 documentations of each operator. The user will find*

*in these documentations the syntax of the operator, as well as the significance of each parameter.*

*In addition, the user who wishes to have more detailed approach and comments on*

*algorithms or the equations of the contact, will refer to the reference materials R5: [R5.03.50]*

*and [R5.03.51].*

*Examples are provided here to illustrate certain points. One will be able in addition to refer to the cases test (V6 documentation) and to be inspired some.*

## ***Plan***

*In a second part, we will give some elementary definitions specific to modeling of the contact.*

*Partly 3, one finds a short description of the Code\_Aster operators concerned.*

*In parts 4 and 5, one will approach the difficulties of modeling and calculation. One will find in these parts councils to use the contact in Code\_Aster.*

*Part 6 is devoted to other modelings of the contact in Code\_Aster. It is reserved for specific contact.*

## ***2 Definitions***

### ***Contact***

*The taking into account of the contact by Code\_Aster does not go from oneself. Without specific declaration, two elements can occupy the same place of space.*

*If it is provided that two surfaces can come into contact during calculation, one should be done declaration of contact. Surfaces in questions are called surfaces of contact.*

*The surface of contact is 2D for a structure 3D, 1D for a structure 2D.*

### *Master/Slave*

*When it is declared that two surfaces S1 and S2 are likely to come into contact, Code\_Aster writes them suitable relations. These relations are not symmetrical. This is why one is brought to distinguish two surfaces, to the first one gives the name of Master, at the second the name of slave. The treatment of the contact consists in preventing the nodes slaves from penetrating surface Master.*

### *Note:*

*For the methods LAGRANGE and CONSTRAINT, Code\_Aster treats the contact while applying multipliers of Lagrange carried by the nodes slaves.*

*One understands in this case that the main choice of surface and surface slave can have one influence on the result of calculation. One will find thereafter councils to make this choice.*

### *Pairing*

*Pairing is the phase of calculation where Code\_Aster calculates between which point slave and which point*

*Master (or which mesh Master) will be written the relations of contact.*

*One calls “NODAL” pairing pairing between a node slave and a main node.*

*One calls pairing “MAITRE-ESCLAVE” pairing between a node slave and his projection on surface Master.*

*Appear 2-a: Pairing “MAITRE-ESCLAVE” and “NODAL” pairing*

**Key S. LAMARCHE**

:

**U2.04.04-A Page**

**: 6/28**

**Normal**

*The normals on the surfaces have a very important role at the time of pairing and writing of relation of the contact.*

*Their direction allows the projection of the points slaves on surfaces Master, but they are too used for the writing of the equations of contact. Their direction makes it possible to distinguish the interior of*

*the outside of the structure. The normals must always be outgoing.*

*This is why it is essential always to define and correctly direct the normals of surfaces in contact.*

**N**

*Appear 2-b: The normal must be outgoing*

**Conditions of Signorini**

*The conditions of Signorini are the conditions of noninterpenetration.*

**Force**

**normal**

**dn**

**Appear 1-c: Condition of Signorini**

*They say that the normal force of contact is null when there is not contact ( $dn > 0$ ), and that the interpenetration (i.e.  $dn < 0$ ) is impossible. If there is contact, normal reaction can take any positive value (effort of repulsion) which answers the mechanical problem and which prevents the interpenetration.*

### *Force contact*

*During the contact, two surfaces in contact generate forces one on the other. These forces allow two surfaces not to interpenetrate. They respect the principle of action and reaction. One has access to these forces during postprocessing.*

*These forces are always forces of repulsion (to move away surfaces in contact). They do not act remotely, i.e. they are null when two surfaces do not touch.*

*U2.04.04-A Page*

*: 7/28*

*Coefficient of friction  $\mu$*

*Friction is taken into account by the law of Coulomb.*

*Appear 2D: Law of Coulomb*

*This law utilizes a coefficient  $\mu$ , called coefficient of Coulomb. During the phase of adherence,*

*the point does not move (null speed). During the phase of slip, the point has a speed not null, it is subjected to a tangent reaction equalizes with  $\mu$  time the normal reaction. The coefficient of Coulomb depends on surfaces in contact. If the coefficient of friction is null (i.e., if there is no friction), there is no reaction tangential.*

### ***Penalization***

*One can treat the contact in a penalized way.*

*For the normal direction, in other words, once in contact, the structure are pushed back by a stiffness. This stiffness exerts a repulsive effort between the structures. During this phase, there is interpenetration of the structures.*

*One fixes this stiffness with the normal coefficient of penalization  $E_N$ .*

***F***

**: 8/28**

***This penalization corresponds to a regularization of the curve of Signorini:***

***Force normal***

$$F = - E_N \cdot dn$$

***dn***

***Appear 2-f: Condition of Signorini penalized***

***For friction, the penalization appears on the curve of Coulomb.***

***In this case, there is no phase of adherence, the infinite slope is replaced by a slope finished of value the tangent coefficient of penalization  $E_T$ .***

***RT***

$$\mu \cdot |RN|$$

$$E_T$$

$$- vT$$

$$- \mu \cdot |RN|$$

***Appear 2-g: Law of Coulomb penalized***

***One should not confuse the tangent coefficient of penalization  $E_T$  with the coefficient of friction  $\mu$ . On the preceding curve, the first fixes the slope at the origin, the second fixes the value of the stage.***

## ***Loads of contact***

***In Code\_Aster, one speaks about loads of contact. All the declarations of the contact are done like a declaration of load. One defines the parameters in AFFE\_CHAR\_MECA and one uses them in key word EXCIT of the operator of calculation.***

## ***Interpenetration***

***One speaks about interpenetration when a structure penetrates inside the other and reciprocally. The interpenetration is not a physical phenomenon. A physical object can come to be crushed on one other but does not penetrate in the matter of the other.***

## ***Instruction manual***

***U2.04 booklet: Nonlinear mechanics***

### ***Exact solution***

*One will use the expression “solution exact” to indicate a solution which follows the laws exactly of contact (conditions of Signorini and law of Coulomb).*

*In particular, an exact solution does not allow the interpenetration.*

*The exact solution is obtained without the recourse to coefficients of penalization chosen by the user, and on which strongly the solution depends.*

*Obviously, an “exact” solution is not inevitably physically acceptable, and it depends always other parameters of calculation and modeling.*

### ***Specific contact***

*One speaks about specific contact when two “surfaces” potentially in contact are reduced to points. For example, on telegraphic models, one can be brought to use the specific contact.*

*One can use the specific contact in 2D or 3D.*

*It should not be confused with nodal pairing where the relations are written between two nodes but where the contact can be done between two surfaces (or segments), and pairings can evolve/move with run of calculation.*

*One can treat the specific contact with the methods presented here. Other methods are too available. They are presented at chapter 6.*

### ***Operators of the contact***

*At the time of the modeling of the contact, one will be brought to use two Code\_Aster operators: AFFE\_CHAR\_MECA which makes it possible to regulate all the parameters of the contact and to declare surfaces of contact.*

*STAT\_NON\_LINE or DYNA\_NON\_LINE which carry out static or dynamic calculation with contact. For each operator, one will refer to U4 documentations. They contain syntax operators, as well as the significance of each keyword.*

**3.1**

#### ***AFFE\_CHAR\_MECA***

*[U4.44.01]*

*AFFE\_CHAR\_MECA, key word CONTACT*

*It is in AFFE\_CHAR\_MECA that one defines the parameters of the loads of contact, under the key word CONTACT.*

*It is here that one chooses surfaces of contact.*

*· The contact will be done between the GROUP\_MA\_1 (or MAILLE\_1) and the GROUP\_MA\_2 (or MAILLE\_2).*

*the declaration of these two elements is essential.*

**Appear 3.1-a: Declaration of surfaces of contact**

*Only the couples of surfaces declared here will be taken into account. If ever the contact were to be done elsewhere, Code\_Aster will not hold account of it.*

*· All the loads of contact must be declared in the same AFFE\_CHAR\_MECA, and in the same key word contact. One will add as many occurrences of this key word there is zones to be declared.*

**Example:**

*CHA = AFFE\_CHAR\_MECA (MODELE=MO,  
DDL\_IMPO=\_F (GROUP\_MA='SOCLE',  
DX=0.0,  
DY=0.0,)*

*CONTACT= (\_F (GROUP\_MA\_1 = "COTE\_AB",  
GROUP\_MA\_2  
=  
"COTE\_EF",  
METHOD  
=  
"LAGRANGIAN",  
PAIRING  
=  
"MAIT\_ESCL",),*

*\_F (  
GROUP\_MA\_1  
=  
"COTE\_MP",  
GROUP\_MA\_2  
=  
"COTE\_RS",  
METHOD  
=  
"LAGRANGIAN",  
PAIRING  
=  
"MAIT\_ESCL",  
FRICTION*

=  
"COULOMB",  
COULOMB  
=  
2.0,)),);

**3.2**

***STAT\_NON\_LINE and DYNA\_NON\_LINE***

*[U4.51.03] and [U4.53.01]*

*STAT\_NON\_LINE and DYNA\_NON\_LINE, key word EXCIT*

*The declaration of the load is very simple, since it is enough to give the name of the load built by AFFE\_CHAR\_MECA.*

*It is necessary of course, to regulate the parameters of specific steps of time... to any mechanical study, without to forget that the problem of contact is nonlinear.*

***Important remark:***

*One cannot use piloting in a problem of contact, nor linear research.*

**Example:**

```
RESU = STAT_NON_LINE (MODELE=MO,  
CHAM_MATER=CHMAT,  
EXCIT=  
(_F (CHARGE=CHA1,  
FONC_MULT=F,)

## **4 Modeling**

*The taking into account of the contact intervenes as of the creation of the grid.  
One will tackle in this part the questions useful to arise at the time of the stages of modeling.  
This reflexion relates to the grid, but also the boundary conditions, the definition of surfaces of contact and the taking into account of friction.*

### **4.1 Grid**

#### **4.1.1 Smoothness of the grid**

*In the majority of the cases, it is preferable to refine the grid in the zones of contact.  
In particular in the curves, a fine grid allows a better definition of the normal.  
If the structure presents angles, a refined grid will make it possible to round them slightly.*

*Appear 4.1.1-a: Grid of an angular structure*

*On the other hand, on rigid levels, the treatment of the contact is satisfied with a coarse grid.*

*Appear 4.1.1-b: Grid of a rigid plan*

#### **4.1.2 Choice of the finite elements**

*All the finite elements are compatible with calculations of contact.  
The meshes of surfaces of contact are surface in dimension 3, linear in dimension 2. They must be defined in the grid, they are not automatically extracted from the meshes voluminal by Code\_Aster.*

*Case of quadratic meshes HEXA20 in 3D, and QUAD9 in hulls:*

*Appear 4.1.2-a: Quadratic mesh with its nodes top (X) and its nodes medium (O)*

*Instruction manual*

*U2.04 booklet: Nonlinear mechanics*

***04/11/03***

***Author (S):***

***Key S. LAMARCHE***

***:***

***U2.04.04-A Page***

***: 13/28***

***In the case of the quadratic elements, Code\_Aster imposes relations kinematics between nodes mediums and the nodes tops. Multipliers of Lagrange are applied to the nodes mediums.***

***The first consequence is that the structure is more rigid.***

***Moreover, if boundary conditions (or of symmetry) are imposed on these elements, one needs them to impose on the nodes tops, but not on the nodes mediums not to create redundancies (two multipliers of Lagrange on the same node).***

***In addition, the multiplier of Lagrange imply the use of larger matrices, and can thus to harm the performances, and to pose problems of memory in the case of very large models.***

### ***4.1.3 Case of the beams***

***There is a problem specific to the beam, it does not have a single normal vector. The user must to fix the direction of the normal with key word VECT\_Y.***

***The conditions of contact will be correctly taken into account only if the contact is done according to this normal.***

***If these restrictions are incompatible with the restrictions of the problem, one can always net beam in 3D.***

### ***4.1.4 Thickness material***

***Key words DIST\_1 and DIST\_2 make it possible to simulate defects of surface which are not represented in the grid. One adds on GROUP\_MA\_1 (or MAILLE\_1) for DIST\_1 and on GROUP\_MA\_2 (or MAILLE\_2) for DIST\_2 a thickness in the direction of the normal. Thus, DIST\_1 > 0 corresponds to a larger thickness, DIST\_1 < 0 with a smaller thickness.***

## ***Appear 4.1.4-a: Use of dist\_1***

### ***Note:***

***This option replaces the grid of defects of surface, but does not simulate the addition of matter (inertia, arm of lever...).***

***interpenetration***

***dist\_1***

***Appear 4.1.4-b: Visualization of an interpenetration***

## **4.1.5 VECT\_Y**

*VECT\_Y, key word of AFFE\_CHAR\_MECA/CONTACT makes it possible to define a local reference mark on a surface*

*of contact. In this case, the local reference mark is built in the following way: the first V1 vector is obtained by orthogonal projection of VECT\_Y on the surface of the element considered, second V2 is obtained by vector product of V1 with the normal vector NR.*

*Is also used it to give a normal to the beams.*

*In this case, VECT\_Y is the vector, which, by vector product with the tangent vector with the beam, give the normal to be used.*

**NR**

**T**

**VECT\_Y**

*Appear 4.1.5-a: Use of VECT\_Y to define the normal in a beam*

*For other uses of VECT\_Y, one can refer to U4 documentation of AFFE\_CHAR\_MECA.*

## **4.2**

### **normals**

*It is imperative that the meshes of contact are defined so that the normals are*

*outgoing.*

*To have outgoing normals, one uses operator MODI\_MAILLAGE, with the mots\_clef ORIE\_PEAU\_2D, ORIE\_PEAU\_3D or ORIE\_NORM\_COQUE, according to modeling [U4.23.04].*

*N*

*Appear 4.2-a: The normal must be outgoing*

*Example:*

```
MA = MODI_MAILLAGE (reuse=MA,  
MAILLAGE=MA,  
ORIE_PEAU_3D= (_F (GROUP_MA=' SURF_1'),
```

```
_F (GROUP_MA=' SURF_2'),),  
MODELE=MO,);
```

### *4.3 Pairing*

*Two methods of pairing are available: “NODAL” or “MAITRE-ESCLAVE”.*

#### *4.3.1 Method*

*“nodal”*

*Pairing is done between a node of surface slave and a main node of surface.*

*With each node slave, one pairs the main node nearest.*

*The relation of noninterpenetration uses by defect the normal with the mesh slave. Direction of approach is either the normal with the mesh Master, or a fixed arbitrary direction (VECT\_NORM\_2).*

*Normal*

*Master*

*Vect\_norm\_2*

*Master*

*Slave*

## 6.4

***Titrate:***  
***Modeling of the contact***

***Date***

***:***

***04/11/03***

***Author (S):***

***Key S. LAMARCHE***

***:***

***U2.04.04-A Page***

***: 16/28***

***Surface Master is that which comprises the most nodes (or if equality MAILLE\_2 or GROUP\_MA\_2).  
Indeed, it is preferable that each main node is paired only with one node slave.***

***The Councils of use:***

***It is advised to have the compatible grids and which remain compatible during calculation.***

***The method "NODAL" does not make it possible to correctly take into account great displacements.***

***One advises to use method "MAITRE-ESCLAVE".***

### 4.3.2 Method

***"maitre-slave"***

***It is the advised method of pairing.***

***It is a pairing node-facet. It is done between a node slave and a facet Master.***

***The condition of contact is that the nodes slaves should not enter the meshes Masters.***

***It is noticed that the reverse is possible.***

***The relation of noninterpenetration uses by defect the normal with the mesh Master. One can also use  
the average enters the normal to the mesh Master and the normal to the mesh slave.***

***Normal***

***Normal***

***slave***

***Master***

***Average of***

***two directions***

***Master***

***Slave***

***Appear 4.3.2-a: Example of use of the average enters the direction  
normal Master and that of the normal slave***

*Surface Master is that defined by GROUP\_MA\_1 (or MAILLE\_1), the mesh slave is that definite by GROUP\_MA\_2 (or MAILLE\_2).*

*This method of pairing can be used in great displacements.*

*Main choice of surfaces and slaves:*

*If a surface is with a grid much more finely than the other, it is better that it is the slave for to limit the interpenetration.*

*If one of surfaces is rigid, it is better that it is surface Master.*

*A surface Master can be paired on several surfaces slaves but a surface slave cannot to correspond that to only one surface Master.*

### **4.3.3 difficulties**

*For the methods FORCED and LAGRANGE, the conditions of contact are imposed by means of multipliers of Lagrange on the nodes slaves (for the methods FORCED and LAGRANGE).*

*However one can put only one multiplier of Lagrange by node and direction.*

*The immediate consequences of this remark are:*

- a point should not belong to several surfaces slaves,*
- the points of surfaces slaves should not carry conditions of Dirichlet (DDL\_IMPO, FACE\_IMPO, LIAISON\_...).*

*Instruction manual*

*U2.04 booklet: Nonlinear mechanics*

**Date**

**:**

**04/11/03**

**Author (S):**

**Key S. LAMARCHE**

**:**

**U2.04.04-A Page**

**: 17/28**

#### **4.3.4 Possible solutions**

*One can gather various surfaces of contact in only one. Surfaces of contact can be angular. They can also be made up of disjointed surfaces of grid.*

*surface slave*

*surface main*

*Appear 4.3.4-a: Example of angular surfaces of contact*

*One can exclude certain points from surfaces slaves. One uses for that key words SANS\_NO and SANS\_GROUP\_NO. This method is used for example to exclude from a surface slave them nodes of an edge on which one imposed a boundary condition.*

#### **4.3.5 A particular case**

*It is possible that surface slave comes into contact with a main prolongation of surface.*

*surface slave*

*surface main*

*Appear 4.3.5-a: Example of contact with the main prolongation of surface*

*There are two solutions with this problem.*

*The first consists in choosing for the widest surface Master.*

*The second consists to widen surface Master and to take into account the other sides. (see [Figure 4.3.4-a]).*

*This behavior can also disturb problems of more complicated geometry.*

### **4.4**

#### **Boundary conditions**

*It is pointed out that a node slave should not carry boundary condition (see paragraph precedent).*

*Calculation must be able to be done even when the contact is removed. In dynamics, that does not impose*

*of particular constraint. In statics, it is necessary that the structure does not hold only by the contact.*

*One will make*

*thus attention to block all the modes of rigid bodies.*

*To block a rigid mode of body, it is enough to apply to the structure a displacement imposed (no one or not) in the direction to be blocked. Another method is to block the mode of rigid body with one comes out from low stiffness which too much will not disturb the result of calculation. This solution is not*

*alleviating and it is advised to check the results of calculation by making a parametric study on stiffness of the spring.*

*: 18/28*

## **4.5 Surfaces**

### **rigid**

*It may be that one of surfaces of the model is infinitely rigid.*

*One will even advise, in a preoccupation with a simplification of the problem, to regard as infinitely rigid any surface much more rigid than the others.*

*The modeling of a rigid surface is done by blocking its degrees of freedom with conditions kinematics.*

*One can also increase his Young modulus to place it at at least an order of magnitude at above Young moduli of other surfaces. But this last method is largely disadvised because it can introduce numerical difficulties.*

*In the case of a problem of contact, rigid surface will be preferably surface Master.*

*The plane parts of rigid surface can be modelled very coarsely. On the other hand, for a better definition of the normals, it is advised to net the curved zones finely.*

*If rigid surface is surface slave, one will not be able to deal with the problem while posing conditions kinematics....*

#### 4.5.1 Extracts of a command file comprising a rigid surface

```

## **4.6**

### ***friction***

*The modeling of friction in 3D is a rather delicate thing. Also, if in a study 3D it coefficient of friction is very low, it is advised to neglect frictions.*

*For a study with friction, it is advised to initially treat it without friction so to give an order of magnitude of the answer and with the aim of introduce the difficulties ones after the others.*

## **5 Calculations**

*It is strongly advised to read U4 documentations of AFFE\_CHAR\_MECA and STAT\_NON\_LINE or DYNA\_NON\_LINE.*

*The contact is treated like a load in the equation of dynamics.*

*The difficulties encountered during calculation are not obligatorily due to the contact.*

*The treatment of the contact is one of nonthe linearities of the problem. The problem can comprise others not linearities.*

### **5.1**

*Taking into account of the contact friction*

*In operator AFFE\_CHAR\_MECA, one is brought to choose the method of calculation of the contact.*

*Three methods are possible: “FORCED”, “LAGRANGE” and “PENALIZATION”.*

#### **5.1.1 “CONSTRAINT”**

*It is based on the algorithm of the active constraints (see documentations R of reference for more details).*

*It is an exact method. It uses the multipliers of lagrange. There is not interpenetration enters structures.*

*One cannot use it with friction.*

*Instruction manual*

*U2.04 booklet: Nonlinear mechanics*

*HT-66/03/002/A*

---

*Code\_Aster ®*

*Version*

*6.4*

*Titrate:*

*Modeling of the contact*

*Date*

*:*

*04/11/03*

**Author (S):**

**Key S. LAMARCHE**

**:**

**U2.04.04-A Page**

**: 20/28**

### **5.1.2 “LAGRANGE”**

*It is an exact method.*

*It uses the multipliers of Lagrange and an algorithm equivalent to that of the method CONSTRAINT.*

*This method allows the use of friction.*

### **5.1.3 “PENALIZATION”**

*This method treats penalized friction (coefficient AND), but the contact is is penalized (coefficient IN) is treated by multiplier of lagrange. It is the user who decides (if it provides IN contact is penalized, if it does not provide it the contact is treated by multiplier of Lagrange).*

#### **5.1.3.1 Choice of the coefficients of penalization**

*The choice of the coefficients of penalization is a delicate choice. More especially as the result obtained is very dependent on this coefficient.*

*The higher the coefficient of penalization will be, the more the result will be close to the exact result. But one too high coefficient of penalization (compared to the other stiffnesses of the problem) can induce numerical problems.*

*In practice, one can start with a coefficient of the same smallest order of magnitude as Young modulus of the problem. Then, one gradually increases it (of a factor 10 for example) until the stabilization of the results.*

**Note:**

*For the coefficient IN, one can validate the result of calculation by checking that the interpenetration is not too large. One can sometimes increase it up to 107 to 108 times the smallest Young modulus.*

#### **5.1.3.2 Advantages and disadvantages**

*The penalization does not induce discontinuity of the fields speed. What can be an advantage in a calculation in dynamics.*

However it is not exact because it authorizes the interpenetration, and the results are very dependent on the coefficients of penalization.

#### **5.1.4 Remarks**

*Here a list of remarks to contribute to the choice of the method.*

*For an elastic design, active method “LAGRANGE” (or constraints if there is not friction) is faster.*

*The penalization gives results very dependent on the coefficients of penalization.*

*In the case of a calculation with penalized friction, one can check his results while testing with one another method.*

*In the case of a penalized normal contact, a checking can be the depth of interpenetration.*

*It should not be too large.*

*It is pointed out that one can use only one method for the conditions of contact of same calculation.*

*In 2D, one will rather use “LAGRANGE” or “CONSTRAINT”.*

#### **5.2 Friction**

*When friction is activated, it is necessary to provide a coefficient of Coulomb friction in all the cases.*

*In*

*3D in surface contact (meshes 2D), it is also necessary to fix the COEFFICIENT\_MATR\_FROT (see U4 documentation). And in the case of a calculation with penalization, it is necessary to give AND (see § penalization).*

## **5.3 Interpenetration**

*At the end of calculation, one can observe an interpenetration of the structures. It can be due to several reasons.*

### **5.3.1 Calculation penalized**

*In the case of a penalized calculation, there is always interpenetration at the time of the contact, since the forces of contact become active when the play is negative. This interpenetration is weaker if the normal coefficients of penalization (IN) are higher.*

### **5.3.2 Dissymmetry Master/slave**

*One can have an interpenetration of the main nodes in surfaces slaves. For some geometries, this phenomenon can become awkward (too major interpenetration, or penetration supplements of a main relief of the mesh in a surface slave). It is enough to net them more finely surfaces slaves in the areas concerned.*

*surface slave  
surface  
Master*

*Appear 5.3.2-a: Example of interpenetration due to dissymmetry Master/slave*

### **5.3.3 Visualization**

*One will of course pay attention to the artifacts of visualization. Like one saw in the § Epaisseur material, if one uses key words DIST\_1 and DIST\_2, one can then to see interpenetration whereas there is not ( $DIST_1 + DIST_2 < 0$ ) or not to see a contact whereas there is ( $DIST_1 + DIST_2 > 0$ ).*

*During a visualization, one is brought to choose a scale factor. This factor multiplies them displacements and makes it possible the user to better observe them. In the case of a study with contact, it is necessary to put this scale factor at 1. If this factor is higher than 1, one can observe much interpenetration where there is not all.*

## **5.4**

## **calculation**

**Calculation is done with STAT\_NON\_LINE or DYNA\_NON\_LINE. It is advised to read documentations**

**U4 associated with its operators. One will be able to also refer to the documents of the Aster formation.**

**At the time to make the choices of the various options, one will not forget that the problem of contact is**

**nonlinear.**

**One will put the question to know if one works into small or in great displacements.**

**It is pointed out that the options of linear research and that of piloting are not possible with contact.**

**Instruction manual**

**Author (S):**

**Key S. LAMARCHE**

**:**

**U2.04.04-A Page**

**: 22/28**

**5.5 Large**

**displacements**

**One considers in this paragraph, the problems in great displacements.**

**The detection of the contact is done according to the geometry of the structure and the relations of not interpenetration are based on the directions of the normals. In the event of great displacements, one thus has**

**need to work on a reactualized geometry.**

**One does not speak here about great deformations. The possibility or not of treating the great deformations**

*does not depend on the contact.*

*In addition, one will choose parameters of calculation in operator STAT\_NON\_LINE or DYNA\_NON\_LINE compatible with a calculation in great displacements.*

### **5.5.1 Seek**

*The research of pairing is done either in the direct vicinity of the node of preceding contact, or on all the structure. In the event of great displacements, one uses research on all the structure.*

### **5.5.2 Reactualization geometry**

*According to if one works into large or small displacements, one will choose a reactualization of different geometry.*

*REAC\_GEOM=' SANS'. In this case, one works on the initial geometry. One uses this choice only for studies in small displacements.*

*For great displacements, one uses one of the two other choices.*

*The choice by defect is:*

*REAC\_GEOM=' AUTO'. The reactualization of the geometry is automatic. It is done until satisfying a geometrical criterion of convergence.*

*One can also impose the iteration count with: REAC\_GEOM=' CONTROLE'. This number is specified*

*with NB\_REAC\_GEOM=n.*

*· Value 1 indicates that with convergence, one reactualizes the geometry and one passes to the step of charge according to.*

*· Value 2 indicates that to convergence, one does not pass to the step of load according to.*

*One reactualizes the geometry and one reiterates until convergence.*

*· The value  $n > 2$  indicates that one makes N cycles reactualization geometrical-iterations until convergence.*

## **5.6**

### **The dynamic case**

*The preceding remarks are valid in statics (STAT\_NON\_LINE) and dynamics (DYNA\_NON\_LINE).*

*One will draw the attention to some points particular to dynamic calculations.*

*In a problem dealt with with multipliers of Lagrange, at the time of the impact speed is discontinuous. Acceleration is thus not defined in this moment.*

*This remark can be in the beginning strong oscillations of the answer, or a strong sensitivity to diagram of calculation used and with the step of time. One strongly advises to start with the step of time which observes the condition of current (time put by the wave to cross an element) then to test several steps of smaller or larger times.*

*One can attenuate the oscillations by using a diagram which generates numerical damping.*

*In the case of a penalized calculation, it is not there a jump speed. This method east can be more correct on a mathematical level, but it generates it also oscillations of the answer to moment of the contact.*

*6 Others*

*methods*

*In this part, one presents two other methods available in Code\_Aster to treat it contact. Their applicability is more restricted (penalized calculation and specific contact) but they have some characteristics which can be useful and which are exposed Ci below.*

*6.1*

*DYNA\_TRAN\_MODAL*

*For the use of this operator, one advises the reading of U4 documentation.*

*For postprocessing, one will read in particular U4 documentation of POST\_DYNA\_MODAL\_T.*

*6.1.1 Presentation*

*DYNA\_TRAN\_MODAL calculates a transitory dynamic response on truncated modal basis. It allows taking into account of contact-friction.*

*The use of this operator supposes that modal calculation is already made.*

*DYNA\_TRAN\_MODAL proposes several methods of calculation. The explicit methods will be used*

*(“EULER”, “DEVOGE”, “ADAPT”) to treat the contact.  
One enters the data relating to contact-friction under the key word “SHOCK”.*

### **6.1.2 Treatment of the contact**

*It is about a specific contact, penalized, in small displacements.  
One can take into account the damping of shock. (It is pointed out that the effect of this damping depends on the step of time.).  
The user potentially provides the couples of nodes in contact, as well as the coefficients of penalization (IN and AND) and of damping.*

### **6.1.3 Modeling**

#### **6.1.3.1 Thickness material**

*It corresponds to the thickness material of the loads of contact.  
It is noticed that a negative initial play is equivalent to a prestressing.*

#### **6.1.3.2 Obstacles nonwith a grid**

*It is possible to take account of not modelled rigid surfaces. They are defined by **DEFI\_OBSTACLE**. They block the displacement of a point inside a defined pre curve, or between two plans.*

*obstacle  
Structure  
defined by  
studied  
**DEFI\_OBSTACLE***

*Appear 6.1.3.2 - has: Example of use of **DEFI\_OBSTACLE***

*These surfaces are infinitely rigid, but one can affect a flexibility to them by the means of coefficients of penalization.*

*Note:*

*One can make evolve/move these obstacles during calculation according to profiles' determined with operators **POST\_USURE** and **MODI\_OBSTACLE**. On this point, it is advised to consult them U4 documentations of **POST\_USURE** and **MODI\_OBSTACLE**, to see on which types of study these calculations are applicable.*

*Instruction manual*

:

**U2.04.04-A Page**

**: 24/28**

#### **6.1.4 The Councils of use**

*The choice of the coefficients of penalizations is in the same way made that for the penalized method of loads of contact.*

*The modal base is worked out and one keeps it in an Aster base. Much time then is gained on transitory calculations.*

*If the problem includes/understands rigid surfaces, or surfaces of contact which do not move, one can model them with **DEFI\_OBSTACLE**.*

#### **6.1.5 Postprocessing**

*The components of the results are directly accessible by **RECU\_FONCTION**.*

***DYNA\_TRAN\_MODAL** have postprocessing specific. They make it possible to make studies of impact or studies of wear. They are accessible starting from **POST\_DYNA\_MODAL\_T** and its options*

*“**IMPACT**” or “**WEAR**”. One will refer to U4 documentation of **POST\_DYNA\_MODAL\_T** for the list postprocessing included/understood in these two options.*

#### **6.1.6 Assessment**

*This method of the treatment of the contact is limited to the specific studies of contact, penalized, into small displacements.*

*Put aside nonlocal linearities envisaged by the operator (like the specific shocks), the problem must be linear, since calculation is made starting from the modal base.*

*In its field of application, it has the advantage of taking into account damping and of laying out of a rich postprocessing.*

*The truncation of the modal base makes it possible to make fast transitory calculations. One will make however*

*attention to choose the size of the base used well. In the case of a study with shock, one can be brought to go up rather high in frequency.*

*The creation of obstacles except grid can represent an important profit of size for the model.*

## ***6.2***

### ***DIS\_CONTACT***

*Elements DIS\_CONTACT make it possible to model a specific contact, penalized, into small displacements. They are discrete elements.*

*Contrary to the preceding chapter, calculation is then direct (operators STAT\_NON\_LINE or DYNA\_NON\_LINE).*

*Elements DIS\_CONTACT are generally elements with two nodes, present in grid. They connect the two points which will be potentially in contact during calculation. There is too elements with a node, for which it is necessary to affect a play in the normal direction of shock*

*(confused  
with the local axis X).*

*These elements have many characteristics which one declares in `DEFI_MATERIAU`.  
One advises the reading of Doc. U4 of `DEFI_MATERIAU` to obtain the exhaustive list of these  
parameters and their definition.*

*The interest of these elements is their great richness of behavior. One can give them laws of  
behavior particular (elastoplastic, dependent on time...).*

*Of course, for multiplying the use of these parameters, it will be necessary to raise the question of  
to know which have a relevant direction for the study.*

*In the command file according to, one uses them to calculate the contact between two beams  
modelled in 3D.*

### **6.2.1 Example of command file**

CREA_GROUP_NO=_F (TOUT_GROUP_MA=' OUI',),);
```

*# beams POU1 and POU2 are in 3D, whereas the elements of shock are the discrete ones. One them  
allot characteristics thanks to operator `DEFI_MATERIAU`. In this study, one chose  
to take account of a damping (which acts that there is contact or not). One indicates also the  
coefficient of  
penalization of the shock.*

*(It is pointed out that the effect of damping depends on the step on time.)*

**:**

**U2.04.05-A Page****: 3/50****1*****The broad outline*****1.1*****Context of studies THM***

***First of all, it is advisable to define the quite precise framework of calculations Thermo-Hydro-Mechanics.***

***Those have as an exclusive application the study of the porous environments. Knowing that, modelings THM***

***cover L`evolution mechanical of these mediums and the flows in their centre. The latter concern one or two fluids and is governed by the laws of Darcy (fluid darcéens). The problem of complete THM***

***draft thus of the flow of or the fluid (S), the mechanics of the skeleton, as well as thermics: the resolution is entirely coupled (and not chained).***

**1.2 General**

***Calculations are based on families of laws of behavior THM for the saturated porous environments and unsaturated. The mechanics of the porous environments gathers a very exhaustive collection of physical phenomena concerning with the solids and the fluids. It makes the assumption of a coupling enters***

***mechanical evolutions of the solids and the fluids, seen like continuous mediums, with hydraulic evolutions, which regulate the problems of diffusion of fluids within walls or of volumes, and thermal evolutions. The formulation of modeling Thermo-hydro-mechanics (THM) in porous environment such as it is made in Code\_Aster is detailed in [R7.01.11] and [R7.01.10]. All the notations employed here thus refer to it. One recalls however some essential notations thereafter:***

***Concerning the fluids, one considers (the most complete case) two phases (liquid and gas) and two components called by convenience water and air. The following indices then are used:***

***W for liquid water***

***AD for the dissolved air***

***have for the dry air***

***vp for the steam***

***The thermodynamic variables are:***

***· pressures of the components: pw (,***

***X T), pad (,***

$X T$ ),  $pvp$  (  
 $X T$ ),  $not$  (  
 $X T$ ),  
 · the temperature of the medium  $T$  ( $X$ ,  $T$ ).

These various variables are not completely independent. Indeed, if only one is considered component, thermodynamic balance between its phases imposes a relation between the pressure of vapor and pressure of the liquid of this component. Finally, there is only one pressure independent by component, just as there is only one conservation equation of the mass. The number of independent pressures is thus equal to the number of independent components. choice of these pressures varies according to laws' of behaviors.

For the case known as saturated (only one component air or water) we chose the pressure of this single component.

For the case says unsaturated (presence of air and water), we chose like variables independent:

· total pressure of the gas  $p$

,

$X T = p + p$ ,

$gz$  (  
 $) vp$  have

· capillary pressure  $p$

,

$X T = p - p = p - p - p$

$C$  (  
 $) gz$

$lq$

$gz$

$W$

$AD$ .

We will see the Aster terminology thereafter for these variables.

## **1.3**

### ***Stages of calculations***

*For the stages necessary to the manufacture of a calculation Aster, independently of the aspects purely THM, one will refer to the documentation of each order used.*

*In the whole of this document one will refer to a typical example of file of calculation given in appendix. In any calculation Aster, several key stages must be carried out:*

- Choix of modeling*
- Données materials*
- Initialisation*
- Calcul*
- Post-traitement*

## **2**

### ***Various stages of calculation***

#### **2.1**

##### ***Choice of the model***

*The choice is done by the use of order AFFE\_MODELE as in the example below:*

```
MODELE=AFFE_MODELE (MAILLAGE=MAIL,  
AFFE=_F (TOUT=' OUI',  
PHENOMENE=' MECANIQUE',  
MODELISATION=' AXIS_THH2MD',),,);
```

*The digital processing in THM requires a quadratic grid since the elements are of type P2 in displacement and P1 in pressure and temperature in order to avoid problems of oscillations. The “MECHANICAL” phenomenon is obligatory whatever the selected type of modeling (with or without mechanics).*

*The user must inform here in an obligatory way the key word MODELING. This key word allows to define the type of affected element in a type of mesh. Modelings available in THM are them following:*

## **MODELING Modeling**

*The generalized constraints and the variables intern all are indicated in [Annexe 1].  
notations used are those defined in [R7.01.11].*

***Notice concerning the digital processing (key word ending in D):***

*Modelings ending in the letter D indicate that one makes an allowing treatment of diagonaliser (“lumper”) the matrix of mass in order to avoid the oscillations. For that them points of integration are taken at the tops of the elements. One advises highly with the user systematically to choose this type of modeling.*

**2.2**

***Definition of material***

*The material is defined by order DEFI\_MATERIAU as in the example below:*

MATERBO=DEFI\_MATERIAU (ELAS=\_F (E=5.15000000E8,  
NU=0.20,  
RHO=2670.0,  
ALPHA=0.),  
COMP\_THM = “LIQU\_AD\_GAZ\_VAPE”,  
THM\_LIQU=\_F (RHO=1000.0,  
UN\_SUR\_K=0.,  
ALPHA=0.,  
CP=0.0,  
VISC=VISCOLIQ,  
D\_VISC\_TEMP=DVISCOL,),  
THM\_GAZ=\_F (MASS\_MOL=0.01,  
CP=0.0,  
VISC=VISCOGAZ,  
D\_VISC\_TEMP=ZERO,)),

```
THM_VAPE_GAZ=_F (MASS_MOL=0.01,  
CP=0.0,  
VISC=VISCOGAZ,  
D_VISC_TEMP=ZERO,),  
THM_AIR DISS=_F (  
CP=0.0,  
COEF_HENRY=HENRY  
),  
THM_INIT=_F (TEMP=300.0,  
PRE1=0.0,  
PRE2=1.E5,  
PORO=1.,

U2.04.05-A Page

: 11/50

One will be able to refer to [§ 3.3.2.3] of the documentation of order STAT\_NON\_LINE [U4.51.03].

**One then defines the “total” pressures and the temperature by:**

$P$   
 $pddl$   
 $pref$   
;  
 $T$   
 $Tddl$   $Tref$   
=  
+  
=  
+

**All the values in entry or exit (boundary conditions or result of IMPR\_RESU) are nodal unknown factors  $ddl$**

$ddl$

$P$

and  $T$

.

**On the other hand in fact the pressures and the total air temperature are used in the laws of**

$P$

$R$

=

***for perfect gases,***

=

***- 3 dT for the liquid and in***

*M*

*K*

*L*

*L*

*L*

***relation capillary saturation/pressure.***

*Let us note that the nodal values can be initialized by key word ETAT\_INIT of the order STAT\_NON\_LINE (cf 2.3).*

*The user must be very careful in the definition of the values of THM\_INIT: indeed, the definition of several materials with values different from the quantities defined under THM\_INIT leads to discontinuous values initial of the pressure and the temperature, which is not in fact not compatible with the general treatment which is made of these quantities. We thus advise with the user following step:*

- if there is initially a uniform field of pressure or temperature, one informs it directly by key word THM\_INIT,*
- if there is a nonuniform field, one defines for example a reference by the key word THM\_INIT of order DEFI\_MATERIAU, and the initial values compared to this reference by key word ETAT\_INIT of order STAT\_NON\_LINE (cf 2.3).*

***TEMP***

*Temperature of reference ref.*

*T*

.

***The value of the temperature of reference entered behind key word TEMP\_REF of order AFFE\_MATERIAU is ignored.***

***PRE1***

*As seen in table 1:*

*For the behaviors: LIQU\_SATU, and LIQU\_VAPE pressure of liquid of reference.*

*For the behavior: GAS pressure of standard gas.*

*For the behavior: LIQU\_GAZ\_ATM pressure of liquid of changed reference of sign.*

*For the behaviors: LIQU\_VAPE\_GAZ, LIQU\_AD\_GAZ\_VAPE and LIQU\_GAZ pressure capillary of reference.*

*PRE2*

*For the behaviors: LIQU\_VAPE\_GAZ, LIQU\_AD\_GAZ\_VAPE and LIQU\_GAZ and pressure of standard gas.*

***Important remark:***

*One never should take a value of PRE2 equal to zero under penalty of problems numerical.*

*PORO*

*Initial porosity.*

*PRES\_VAPE*

*Initial steam pressure for the behaviors: LIQU\_VAPE\_GAZ, LIQU\_AD\_GAZ\_VAPE, LIQU\_VAPE and LIQU\_GAZ.*

**Note:**

*The initial vapor pressure must be taken in coherence with the other data. Very often, one leaves the knowledge of an initial state of hygroscoy. The degree hygrometrical is the relationship between the steam pressure and the steam pressure saturating at the temperature considered. One then uses the law of Kelvin which gives pressure of the liquid according to the steam pressure, of the temperature and of*

*0**p**p**R**p**W -**saturating steam pressure:**W =**T ln**vp**ol**sat**. This relation is not**M**W**vp**p (T)**vp*

*valid that for isothermal evolutions. For evolutions with variation of temperature, knowing a law giving the steam pressure saturating to*

*The correspondence between name of component Aster and physical size is clarified in [Annexe 1].*

*The initialization of the nodal unknown factors as well as the difference between initial state and state of reference have*

*summer described and detailed in [2.2.3]. It is pointed out nevertheless that*

*ddl*

*ref.*

*p = p*

*+ p for the pressures*

*ddl*

*PRE1 and PRE2 and*

*ref.*

*T = T*

*+ T for the temperatures, where ref.*

*p and ref.*

*T*

*are defined under the key word*

*THM\_INIT of order DEFI\_MATERIAU.*

Key word *DEPL* of the key word factor *ETAT\_INIT* of order *STAT\_NON\_LINE* defines the values initial of {} *ddl*

*U*

. The initial values of the densities of the vapor and the dry air are defined starting from the initial values of the vapor and gas pressures (values read under the key word *THM\_INIT* of order *DEFI\_MATERIAU*). It is noticed that, for displacements, decomposition

*ddl*

*ref.*

$U = U$

+ *U* is not made: key word *THM\_INIT* of order *DEFI\_MATERIAU* thus does not allow to define initial displacements. The only way of initializing displacements is thus to give them an initial value by the key word factor *ETAT\_INIT* of the order *STAT\_NON\_LINE*.

Concerning the constraints, the fields to be informed are the constraints indicated in appendix I according to selected modeling.

Initial values of the enthalpi, which belong to the generalized constraints are defined in to leave key word *SIGM* of the key word factor *ETAT\_INIT* of order *STAT\_NON\_LINE*. The introduction

initial conditions is very important, for the enthalpi. In practice, one can reason in considering that one has three states for the fluids:

· the state running,

- *the state of reference: it is that of the fluids in a free state. In this state of reference, one can consider that the enthalpies are null,*
- *the initial state: it must be in thermodynamic balance. For the enthalpies of water and vapor one will have to take:*

*init**init m**pw - ref.**init**pl**pw - p**hw =**=**atm**W**W**init m**vp**H = L (init**T**) = heat**vaporisati**of**latent**one**init m**have**H = 0**init m**AD**H**= 0**and with  $L(T) = 2500800 -$* *(  
 $2443 T - 273.15) \text{ J/kg}$* **Note:***The initial vapor pressure will have to be taken in coherence with these choices (cf [§2.2.3]).*

Concerning the mechanical constraints, the partition of the constraints in constraints total and effective is written:

$$= ' \\ + \mathbf{I} \\ p$$

where is the total constraint, c.a.d that which checks:

$$( \\ \mathbf{Div}) + m \\ RF = 0$$

is the effective constraint. For the laws of effective constraints, it checks:

$$1 \\ D = F ( \\ D - \\ = +T \\ 0dT, ), \text{ where}$$

( $\mathbf{U} \mathbf{U}$ ) and represents the internal variables.

2  
is calculated according to the water pressures. The adopted writing is incremental and, if one

p  
wants that the value of is coherent with value ref.

p ( \\ p \\ PRE1) definite under the key word \\ THM\_INIT, it is necessary to initialize by the key word

p \\ SIGM of the key word factor ETAT\_INIT of the order \\ STAT\_NON\_LINE.

**Warning:**

*In the case of fields of pressures or temperatures heterogeneous, it is necessary to ensure “manually continuity” enters the fields. That Ci for the moment is not taken into account automatically.*

*In the current state, the degrees of freedom (ddl) to the nodes located at the interface between two meshes take the value of the ddl material initialized in the last as on the figure. Consequently it materials affected in first is found with heterogeneous values of displacements. To ensure continuity, it is necessary to impose on the nodes medium (in grayed on [Figure 2.3-a]) an average value enters*

*two materials. This treatment necessary in is seen of a correct postprocessing but does not have of impact on calculation in him even.*

*Value with the node of the ddl sunken for the mesh*

*M1 (affected in first)*

*M2*

*M1*

*Value with the node of the ddl sunken for the mesh*

*M2 (affected as a second)*

*Value to be modified (average between M1 etM2)*

**Appear 2.3-a: Management of discontinuities between two meshes**

*If one refers to the example presented in [§Annexe 3], the fields of displacements initialized in ETAT\_INIT are then defined for example in the following way:*

```
CHAMNO=CREA_CHAMP (MAILLAGE=MAIL,
OPERATION='AFFE',
TYPE_CHAM='NOEU_DEPL_R',
AFFE= (_F (TOUT='OUI',
NOM_CMP='TEMP',
VALE=0.0,),
_F (GROUP_NO='SURFBO',
NOM_CMP='PRE1',
```

```

VALE=7.E7,),

## **2.4**

### **Loadings and boundary conditions**

*All the boundary conditions or loading are affected via order AFFE\_CHAR\_MECA [U4.44.01]. The loadings are then activated by the key word factor EXCIT of the order STAT\_NON\_LINE.*

*In a traditional way, two types of boundary conditions are possible:*

*· Of the conditions of the Dirichlet type which consist in imposing on part of border of values fixed for principal unknown factors belonging to {} ddl*

*U*

*(and not*

*ddl*

*init*

*U = U + U)*

*for that one uses key word factor DDL\_IMPO of AFFE\_CHAR\_MECA.*

*· Of the conditions of the Neuman type which consist in imposing values on the “quantities dual”, either by not saying anything (null flows), or in their giving a value via the key words FLUN, FLUN\_HYDR1 and FLUN\_HYDR2 of the key word factor FLUX\_THM\_REP of the order AFFE\_CHAR\_MECA. This flow is then multiplied by a function of time (by defect equalizes with 1) in under the word key one EXCIT of order STAT\_NON\_LINE. Mechanical conditions in total constraints .n is they given via PRES\_REP of the order AFFE\_CHAR\_MECA. One will refer to the documentation of this order to know some possibilities.*

*From a syntactic point of view the conditions of Dirichlet thus apply as to the example according to*

*DIRI=AFFE\_CHAR\_MECA (MODELE=MODELE,*

*DDL\_IMPO= (\_F (GROUP\_NO=' GAUCHE',*

*TEMP=0.0,)*

*\_F (TOUT=' OUI',*

*PRE2=0.0,)*

```
_F (GROUP_NO=' GAUCHE',  
PRE1=0.0),  
_F (TOUT=' OUI',  
DX=0.0),  
_F (TOUT=' OUI',  
DY=0.0),  
_F (TOUT=' OUI',  
DZ=0.0),  
,)
```

*For the conditions of Neuman, syntax will be then as on the following example:*

```
NEU1=AFFE_CHAR_MECA (MODELE=MODELE,  
FLUX_THM_REP=_F (GROUP_MA=' DROIT',  
FLUN=200.,  
FLUN_HYDR1=0.0,  
FLUN_HYDR2=0.0),);  
NEU2=AFFE_CHAR_MECA (MODELE=MODELE,  
PRES_REP=_F (GROUP_MA=' DROIT',  
PRES=2.,),);
```

*One defines then the multiplicative function which one wants to apply, for example with NEU1:*

```
FLUX=DEFI_FONCTION (NOM_PARA=' INST',  
VALE=  
(0.0, 386.0,  
315360000.0, 312.0,  
946080000.0,12.6),);
```

*Instruction manual*

*U2.04 booklet: Nonlinear mechanics*

*HT-66/04/004/A*

---

**Code\_Aster** ®

*Version*

7.4

*Titrate:*

*Note of use of model THM*

*Date:*

*Author (S):*

**S. GRANET, C. CHAVANT** *Key*

:  
*U2.04.05-A Page*  
 : 26/50

*The loadings are then activated in STAT\_NON\_LINE via key word EXCIT in the manner following:*

```
EXCIT= (
_F (CHARGE=DIRI,)
_F (CHARGE=NEU2,)
_F (CHARGE=NEU1,
FONC_MULT=FLUX,)
),
```

*FLUN corresponds to the value of the heat flow. FLUN\_HYDR1 and FLUN\_HYDR2 correspond to values of the hydraulic flows associated pressures PRE1 and PRE2. If there is no ambiguity for thermics or mechanics, on the other hand unknown factors principal hydraulic PRE1 and PRE2 change according to the selected coupling. As it below is pointed out*

*Behavior*  
*LIQU\_SATU*  
*LIQU\_VAPE LIQU\_GAZ\_ATM*  
*GAS*  
*LIQU\_VAPE\_GAZ*

*LIQU\_GAZ*  
*LIQU\_AD\_GAZ\_VA*

*p*  
*p*  
*- p*  
*p*  
*p = p - p*  
*lq*  
*lq*  
*lq*  
*G*  
*C*  
*G*  
*lq*  
*PRE2*

*pg*

*Associated flows are:*

*For*

*ext.*

*PRE1, FLUN\_HYDR1: (M + M*

*N*

*. = M*

*+ M*

*W*

*vp)*

*ext.*

*W*

*vp*

*For*

*ext.*

*PRE2, FLUN\_HYDR2: (M*

*+ M N*

*. = M*

*+ M*

*AD*

*have)*

*ext.*

*AD*

*have*

*We thus will summarize the various possibilities by distinguishing the case where one imposes values on PRE1 and/or PRE2 and that where one works on combinations of the 2. It is announced that one can well on*

*to have various types of boundary conditions according to the pieces of border (groups of nodes or of meshes) which one treats. For a more complete and more detailed outline in the way in which are treated the boundary conditions in the case unsaturated, one will refer to the note reproduced in appendix 2.*

***· Cas of the boundary conditions utilizing unknown factors principal PRE1 and PRE2***

*One summarizes here the usual case where one imposes value on PRE1 and/or PRE2.*

*- Dirichlet on PRE1 and Dirichlet on PRE2*

*The user imposes a value on PRE1 and PRE2; flows are results of*

calculation.

- Dirichlet on PRE1 and Neuman on PRE2

The user imposes a value on PRE1 and a value with flow associated with PRE2 in saying anything on PRE2 or by giving a value to FLUN\_HYDR2.

- Dirichlet on PRE2 and Neuman on PRE1

The user imposes a value on PRE2 and a value with flow associated with PRE1 in saying anything on PRE1 or by giving a value to FLUN\_HYDR1.

- Neuman on PRE2 and Neuman on PRE1

Two flows are imposed either by not saying anything on PRE1 and/or PRE2 (null flows) maybe by giving a value to FLUN\_HYDR1. et/ou FLUN\_HYDR2

**· Cas of the boundary conditions utilizing a linear relation between unknown factors principal PRE1 and PRE2**

It is also possible to handle linear combinations of PRE1 and PRE2. It is necessary however to handle that with precaution so as to start from a correctly posed problem. The syntax of this operator is detailed in the documentation of AFFE\_CHAR\_MECA, the example below into famous this type of condition:

```
P_DDL=AFFE_CHAR_MECA (MODELE=MODELE,  
LIAISON_GROUP= (_F (  
GROUP_NO_1= "EDGES",  
GROUP_NO_2= "EDGES",  
DDL_1=' PRE1',
```

```

DDL_2=' PRE2',
COEF_MULT_1 = X,
COEF_MULT_2 = Y.,
COEF_IMPO =z,,),
);

```

*This order means that on the border defined by the group of nodes “EDGES”, the pressures PRE1 and PRE2 are connected by the linear relation*

$$X \text{ PRE1} + y \text{ PRE2} = Z$$

**Note:**

*Flows imposed are scalar quantities which can apply to a line or a surface interns with the modelled solid. In this case, these boundary conditions correspond to a source.*

## 2.5

### **Nonlinear calculation**

*Calculation is carried out by order STAT\_NON\_LINE as in the example below:*

```

U0=STAT_NON_LINE (MODELE=MODELE,
CHAM_MATER=CHMAT0,
EXCIT= (
_F (CHARGE=T_IMP,),
_F (CHARGE=CALINT,
FONC_MULT=FLUX,,),
COMP_INCR=_F (RELATION=' KIT_THHM',
RELATION_KIT= (“ELAS”, “LIQU_GAZ”
, “HYDR_UTIL”)),
RECH_LINEAIRE =_F (RESI_LINE_RELA = 1.E-3,
RHO_MIN = 0.1,
RHO_MAX = 0.2,
ITER_LINE_MAXI = 3,),
ETAT_INIT=_F (DEPL=CHAMNO,
SIGM=SIGINIT),
INCREMENT=_F (LIST_INST=INST1,),
NEWTON=_F (MATRICE=' TANGENTE', REAC_ITER=10,),
CONVERGENCE=_F (RESI_GLOB_MAXI=1.0000000000000001E-05,
ITER_GLOB_MAXI=150,
ARRET=' NON',
ITER_INTE_MAXI=5,),
ARCHIVAGE=_F (PAS_ARCH=1,,);

```

*To this order one assigns the model (key word **MODELS**), le/les materials (key word **CHAM\_MATER**), le/les loadings (key word **EXCIT**) and the initial state (key word **ETAT\_INIT**) which one defined by all orders described previously.*

*For general information concerning this order and his syntax, one will refer to its documentation. It is specified just that the method of calculation is a method of Newton.*

**Caution:**

*Under the key word factor **NEWTON**, one must put a “**TANGENT**” matrix of the type and not “**ELASTIC**”.*

*One speaks here only about what is specific to calculations **THM** with knowing the key words factors **RELATION** and **RELATION\_KIT** of the key word **COMP\_INCR** which are closely dependent.*

***RELATION** is indicated by relations of the types which make it possible to solve at the same time from two to four equilibrium equations. The equations considered depend on suffix with the following rule:*

***M** indicates the mechanical equilibrium equation,*

***T** indicates the thermal equilibrium equation,*

***H** indicates a hydraulic equilibrium equation.*

***V** indicates the presence of a phase in form vapor (in addition to the liquid)*

*Only one letter H means that the porous environment is saturated (only one variable of pressure p), by example either of gas, or of liquid, or of a liquid mixture/gas (of which the pressure of gas is constant).*

*Two letters H mean that the porous environment is not saturated (two variables of pressure p), by example a liquid mixture/vapor/gas.*

*The presence of two letters HV means that the porous environment is saturated by a component (with practical of water), but that this component can be in liquid form or vapor. There is not whereas one conservation equation of this component, therefore only one degree of freedom pressure, but there is a flow*

*liquid and a flow vapor. The possible relations are then the following ones:*

*/“KIT\_HM”*

*/“KIT\_THM”*

*/“KIT\_HHM”*

*/“KIT\_THH”*

*/“KIT\_THV”*

*/“KIT\_THHM”*

*The table below summarizes to which kit each modeling corresponds:*

*KIT\_HM*

*D\_PLAN\_HM, D\_PLAN\_HMD, AXIS\_HM, AXIS\_HMD, 3D\_HM, 3D\_HMD*

*KIT\_THM*

**Note:**

*In the event of problem of convergence it can be very useful to activate linear research as indicated in the example given at the head of this section. Linear research do not improve however systematically convergence, it is thus to handle with precaution.*

**2.6**  
**postprocessing**

*The post processing data in THM does not vary a post usual Aster treatment. One recalls just that for any impression of the values which are not the nodal unknown factors, it is necessary to calculate these values by the order CALC\_ELEM whose one gives an example hereafter.*

*For the constraints:*

```
U0=CALC_ELEM (reuse =U0,  
MODELE=MODELE,  
CHAM_MATER=CHMAT0,  
TOUT_ORDRE=' OUI',  
OPTION= (“SIEF_ELNO_ELGA”),  
RESULTAT=U0,);
```

*Instruction manual*

*U2.04 booklet: Nonlinear mechanics*

*HT-66/04/004/A*

---

**Code\_Aster** ®

Version

7.4

Titrate:

*Note of use of model THM*

Date:

06/07/04

Author (S):

**S. GRANET, C. CHAVANT** Key

:

U2.04.05-A Page

: 31/50

*For the internal variables:*

```
U0=CALC_ELEM (reuse =U0,  
MODELE=MODELE,  
CHAM_MATER=CHMAT0,  
TOUT_ORDRE=' OUI',  
OPTION= ("VARI_ELNO_ELGA"),  
RESULTAT=U0,);
```

*It should however be recalled that all the values of displacements at exits correspond to ddl*

*U*

*and*

*not*

*ddl*

*ref.*

*U = U*

*+ U.*

*It is also important to know the name of the constraints and the numbers of the internal variables.*

*All that is consigned in appendix I.*

*Thus the following example makes it possible to print the liquid water mass on the HIGH group of nodes to all*

*moments.*

```
TAB1=POST_RELEVE_T (ACTION=_F (INTITULE=' CONT',  
GROUP_NO= ("HIGH"),  
RESULTAT=U0,  
NOM_CHAM=' SIEF_ELNO_ELGA',
```

```
TOUT_ORDRE=' OUI',  
NOM_CMP= ("M11"),  
OPERATION=' EXTRACTION',,);
```

```
IMPR_TABLE (TABLE=TAB1,  
FICHIER=' RESULTAT',  
FORMAT=' AGRAF',  
PAGINATION=' INST',  
NOM_PARA= ("INST", "COOR_X", "M11"),);
```

*The following example makes it possible to print the values of porosity to node 1 and the first moment.*

```
TAB2=POST_RELEVE_T (ACTION=_F (INTITULE=' DEPL',  
NOEUD=' NO1',  
RESULTAT=U0,  
NOM_CHAM=' VARI_ELNO_ELGA',  
NUME_ORDRE=1,  
NOM_CMP= ("V2"),  
OPERATION=' EXTRACTION',,);  
IMPR_TABLE (TABLE=TAB2,  
FICHIER=' RESULTAT',  
FORMAT=' AGRAF',  
PAGINATION=' INST',  
NOM_PARA= ("INST", "COOR_X", "V2"),);
```

*Concerning the layout of isovaleurs IDEAS as GIBI are the two tools used.*

### **2.6.1 Isovaleurs with Gibi**

*A file .cast readable by orders GIBI east creates via order IMPR\_RESU as on the example below:*

```
IMPR_RESU (RESU=_F (FORMAT=' CASTEM',  
RESULTAT=U0,  
MAILLAGE=MAIL,  
NUME_ORDRE=1,)),
```

*The file obtained is then read by a file of treatment. An example of files gibi of treatment data is in [§Annexe 4].*

One deduces some

$\mathbf{M} . \mathbf{N} = \mathbf{M}$

on

2

have  
ext.  
D

· **Dirichlet PRE2, neuman PRE1**

It is the case where one imposes a value on PRE2 and a value with flow associated with PRE1, by not saying anything on PRE1 or by giving a value to FLUN\_HYDR1 of FLUX\_THM\_REP in AFFE\_CHAR\_MECA. Let us call **M1ext** this

imposed quantity, which will be worth 0 if nothing is known as relative with PRE2. We will note

imp  
p  
p  
2 =  
the condition  
2

imposed on PRE2

This corresponds to:

imp  
pgz = not + pvp = p gz  
imp  
imp  
p  
= p  
2  
gz

The demonstration is the same one as in the preceding paragraph and leads to:

(**M** + **M** .n =M on

1

lq  
vp)  
ext.  
D

**A5.3 Case of boundary conditions utilizing relations linear between principal unknown factors**

*Code\_Aster makes it possible to introduce like boundary conditions of the relations between degrees of freedom, carried by the same node or different nodes. This possibility is reached via key word LIAISON\_DDL of order AFFE\_CHAR\_MECA.*

*That is to say imp*

*p*

*the value which one wants to impose on the pressure of liquid on*

*D. Taking into account [éq A5.1-5], and*

*lq*

*choice of the principal unknown factors for this behavior, one writes:*

*imp*

*p - p = p*

*éq A5.3-1*

*2 - p1 = p*

*gz*

*C*

*lq*

*The linear relations are treated in Aster by introduction of multipliers of Lagrange. This corresponds in the species with the following formulation:*

*To find 1*

*p, p2, μ such as:*

*- m*

*m*

*D*

*M*

*M*

*(M +M +M .n =0*  
*on*

**éq A5.3-4**

*lq*  
*vp*  
*have)*

*D**A5.4 nonlinear cases*

*We do not make here that to tackle more difficult questions consisting in imposing either the steam pressure or pressure of dry air. Taking into account the relations [éq A5.1-7], [éq A5.1-8] and [éq A5.1-9] to impose a value on steam pressure amounts imposing a nonlinear relation on the pressure of liquid. In the same way to impose one pressure of dry air.*

*As example, we approach the case of a pressure of dry air imposed for a behavior LIQU\_VAPE\_GAZ, and we suppose that we can write the nonlinear relation connecting the pressure of vapor and pressure of liquid.*

*The relation to be imposed is thus:  
imp  
 $p = p - p = p$*

*éq A5.4-1**2 - p**= p**have**gz**vp**vp**have*

*By differentiating this relation, one will find a condition on the virtual variations of pressures:*

*p**p**vp**vp**dp = dp -**dp = dp -*

*dp - dp*

*have*

*gz*

*lq*

*gz*

*(gz c)*

*p*

*p*

**1 How to simulate the digging of a tunnel with**  
**Code\_Aster?**

**1.1**

**Principle of the method, implemented and validation**

**Context**

**The studies of géomechanics are generally based on a simulation of roadway drivage underground. Examples of application can be quoted:**

- to evaluate the zone damaged by excavation (EDZ) around a gallery of storage;**
- to study the resaturation of an cell of storage by water of the site.**

**A certain number of studies were already carried out by department AMA on this subject, with Code\_Aster. However, few elements practise are available in documentations for to reproduce this type of calculation. Department MMC undertook such a modeling with Code\_Aster, in order to adapt the procedure of application of the method classically used for this kind of calculation: method “convergence containment”. It comes out from this experiment that this application is not completely commonplace that it is necessary to raise some questions techniques practise of implementation. To capitalize this experiment for the future users is appeared like rather important, in the collective interest of the studies on storage in particular.**

**Objective**

*This note has as a principal objective to provide some preliminary technical councils to users of Code\_Aster wishing to model an underground excavation.*

## ***Methodology***

*This note presents an application to a command file of Code\_Aster of the method convergence containment. After a short recall on the principle of the method, a description practical and operational of the orders to be used is given. The method is illustrated by calculations of validation of Code\_Aster, whose command files are provided in appendix.*

## ***Result***

*Thanks to the application of the protocol suggested, two calculations of validation of Code\_Aster were implemented. The relative difference between numerical results and analytical solution is lower than 2%.*

## ***Outlines***

*The method can be extended to the calculations nonlinear (plasticity, damage) and coupled in THM, in particular within the framework of studies intended for the storage of nuclear waste.*

## ***2 Introduction***

***For several years, studies have been carried out with Code\_Aster in order to model it***

*behavior of works geotechnics (earth dams, tunnels, barriers worked for storage of waste...).*

*Code\_Aster was already used in particular to simulate the well or roadway drivage, in tally of Stockage the geological project of nuclear waste HAVL (T4-01-10) or at the time of studies former on major storage. Reports/ratios written until now (for example [bib6], [bib7] or [bib4]) focus themselves naturally on the results, in order to answer the precise technical question who justified the study. However to simulate an excavation using a code finite elements is not inevitably an easy thing, and even if the general principles are recalled in the documents referred to above, one finds finally few elements on the structure of the command files which served as support with calculations.*

*In order to help the engineers in load of the future studies of underground excavation with Code\_Aster, this note indicates some useful recommendations to begin in the realization from this type of calculation.*

*Indeed, within the framework of the Storage project, MMC decided to adapt the step completely implementation by AMA in 2000 and 2001. For that purpose, all the step was reproduced with version 6 of Code\_Aster, on the basis of grid new and by exploring some alternatives. MMC also profited from the assistance of the agents of AMA. In addition, this work led to one validation of Code\_Aster according to traditional analytical formulas in linear elasticity (formulas kirsch and method convergence-containment, [bib5]).*

*This report/ratio thus presents:*

- traditional method of simulation of an underground excavation in 2D by means of a code finite elements;*
- different the option available to apply this method with Code\_Aster;*
- two case-tests of validation of Code\_Aster for the problems of underground excavations.*

*Thenecessary one with an advantageous reading of this note is the basic training with the use of Code\_Aster as well as a minimum of familiarisation to the software package. The detail of the various orders used is given by the user's documentation of Code\_Aster (<http://www.code-aster.org>).*

***A method to simulate the digging of a gallery with  
to start from a model 2D***

***: the method convergence  
containment***

***3.1 Principle  
general***

***This part is inspired largely by [bib5]. Let us announce that the CIH and TEGG also carried out one certain number of studies with this method (for example, [bib2]). It is advised with the reader of to defer to these documents for more information on the principle of the method. The paragraphs which follow summarize only the essence of the step.***

***The method convergence-containment is usually used in engineering of the works undergrounds. Its objective is to obtain an order of magnitude of displacements of the walls of the tunnel as well as the efforts taken again by the rock and supporting. This method makes it possible to simplify calculation of a three-dimensional work by a two-dimensional calculation, the introduction of a parameter adimensional called "rate of déconfinement". It rests on the following assumptions:***

- plane deformations with assumption of small disturbances;***
- the tunnel is supposed of circular section and horizontal axis;***
- homogeneous ground of infinite extension;***
- massive according to a linear or elastoplastic elastic behavior;***
- initial state of the constraints presumedly isotropic and homogeneous;***
- deep tunnel: no significant variation of constraints on the height of the gallery. In practical, if  $H$  is the average depth of the work and  $R$  its ray, this assumption is***

*presumedly satisfied if  $H/R > 10$ ;*

*· quasi-static balance (not of terms of acceleration).*

*One is interested in a section located in a plan perpendicular to the axis of the tunnel and one wishes to carry out a two-dimensional calculation. The parameter is supposed to take into account the mechanical influence*

*proximity of the coal face to this section, i.e. of a phenomenon whose origin is out of the plan considered by calculation. depends on several parameters (rock, supporting, length of nonconstant tunnel behind the coal face...) and its determination is not inevitably immediate (many publications on the subject, for example [bib1]). This problem of analytical determination rate of déconfinement leaves the framework of this document.*

*In fact, one introduces to consider a fictitious tensor of the constraints in the ground, which is one fraction of the initial constraint  $\sigma_0$*

*:*

*= (1 -  $\nu$ )  $\sigma_0$*

*. with  $\nu = 1$*

**R=0**

**R=0**

**R= (1) .0**

**Appear 3.1-a: Evolution of the rate of déconfinement and the radial constraint R**

**in the case of a nonconstant tunnel**

**Let us notice that = 1 corresponds to déconfinement total of the rock: the influence of the coal face on the behavior of the section of tunnel disappeared and the tunnel is comparable to a very thick tube.**

**Since a part, even the totality of the constraints initially present within the solid mass disappear (it is precisely the phenomenon of déconfinement), the walls of the excavation go to tend to approach to reach a new mechanical balance. It is the phenomenon of “convergence”. This phenomenon can lead to the ruin of the work if the structure does not arrive to to find a state of steady balance following the excavation.**

**If, for reasons of safety or stability, one decides to pose a supporting or a coating to the wall of the tunnel, those go, from their mechanical stiffness, to be opposed to the natural phenomenon**

**convergence. In this case, final balance thus depends on the mechanical interaction between the rock and it**

**coating. Generally, this balance does not allow the constraints in the rock solid mass to cancel itself like in the case of the nonconstant tunnel. It is said whereas the ground is confined, from where it**

*Graphically, the application of this method amounts seeking the point of intersection of the curve of convergence, deduced from the behavior of the ground, and curve of containment, deduced from behavior of supporting [Figure 3.1-b].*

*Appear 3.1-b: Example of curves of convergence and containment*

*Equations of the method “convergence-containment” in the case of a linear elastic solid mass are provided in [Annexe 1].*

*That it is for analytical or numerical calculations, this method allows, using simple model 2D, to deal with the 3D problem which the simulation of an excavation constitutes.*

**3.2 Application of the method for a numerical calculation by elements finished**

*A characteristic of calculations of excavation by finite elements is the need for implementing several models (in the broad sense).*

*Indeed, a traditional course of modeling can be summarized by the following stages:*

- stage 1: initialization of in situ constraints;*
- stage 2: calculation of the nodal reactions on the level of the walls of the excavation;*
- stage 3: déconfinement solid mass to simulate the progressive excavation and the distance of coal face;*
- stage 4: possible installation of a supporting/coating and end of déconfinement.*

*If the study requires it, the sequence of stages 2, 3 and 4 can be repeated (case of an excavation in divided sections, for example).*

***Appear 1.2-a: Typical example of sequence of a calculation of excavation with a computer code***

***The first configuration is used for:***

- to initialize the constraints of origin geostatics;***
- to initialize the hydrostatic pressure due to the possible presence of water and the temperature ( present note does not discuss this precise item in detail);***

***The second configuration makes it possible to calculate the reactions to the nodes representing the edge of the excavation.***

***At these stages of modeling, all the elements of the grid thus correspond to a material of ground type or rock. One thus obtains a solid mass of ground in which reign a state of stresses***

*corresponds to the state of in situ stresses in the plan perpendicular to the axis of the gallery. One knows*

*also nodal reactions at the edge of the excavation, which will allow déconfinement partial or total of the solid mass in the stages which follow.*

*The third configuration is dedicated to déconfinement: one decreases the nodal reactions at the edge of*

*the excavation in order to simulate the digging of the tunnel. At the time of the realization of this stage, the elements*

*stop in the area corresponding inside the gallery do not have to take part more in the rigidity of model. As it further will be seen, this can be taken into account in several ways in practice.*

*One possibly passes to a fourth stage if one wants to simulate the installation of a supporting concrete in the course of déconfinement for example. In this case, one adds elements with characteristics of concrete and one continues the reduction in the nodal reactions calculated in the stage  $n \cdot 1$*

*to complete calculation.*

*It is thus noticed that certain parts of the initial model will be seen affecting successively properties of ground, “concrete vacuum” then. In this sequence is the source of some intrinsic difficulties with this kind of calculation.*

*The application of this step by means of Code\_Aster is covered in the following chapters. It is based on a simple case.*

***How to define the models starting from a simple grid?***

***The grid chosen in this study represents a quarter of model representing a gallery cylindrical in infinite medium. The ray of the gallery is 1,50 meter, the thickness of concrete is 0,30 measure and the grid is a square of 20 side meters. According to the usual rules of modeling, it relationship between the ray excavated R and dimension characteristic of the grid L is sufficient for to consider that the boundary conditions do not disturb the behavior of the excavation (L 10 X R).***

*From the point of view of the models (with the Code\_Aster direction), it is necessary to distinguish some particular zones from grid (in addition to the other more traditional zones, like the edges of the grid) and to create the objects following (the names refer to the command files presented in Appendix):*

- the excavated edge where will be applied the nodal reactions to simulate déconfinement (called EDGE);*
- the two points which are located at the ends of this curve, which are concerned at the same time by the loading of déconfinement and by the boundary conditions at the edge of the solid mass.*

*Appear 4.1-b: Points and of points particular to identify together in the Code\_Aster models*

*One can thus define (for example, because several configurations are possible):*

- a model GROUND, in which all the grid is affected finite elements;*
- a model SOL\_REST which does not include/understand the meshes which correspond to the excavated part (they are not affected finite elements);*
- a model SOL\_REST0 which includes/understands SOL\_REST and the meshes corresponding to the coating out of concrete affected of finite elements.*

*Note:*

*The use of such a geometry to make a real calculation of excavation is partially criticizable, because symmetry suggested risk to generate a nonphysical loading. In case of application of the actual weight for example, this one would be directed upwards in the part lower of the tunnel!*

*For a realistic study where one would wish to initialize the constraints using a loading in weight clean, it would be thus necessary “to net the ground” to the rigid substratum (rock considered indeformable), or all at least until a sufficient depth to be been free from the problem evoked above. One thus nets a half-model in this case there.*

*However, within the framework of our study, this constraint of grid did not obstruct us, since we took into account neither the actual weight, nor couplings THM. The simulated loading is very with fact compatible with the analytical solutions tested.*

## 4.2

### ***How to initialize the constraints?***

*In situ constraints are generally represented by a tensor of order 2 of which directions principal correspond to the vertical and the horizontal one. The vertical constraint is generally equalize with the weight of the various formations located above the point considered and the constraint horizontal is proportional to the vertical constraint:*

$$v = .z$$

$$H = K 0$$

$$. v$$

*with the voluminal weight of the overlying ground (in kN/m<sup>3</sup> for example) and K0 a coefficient without dimension. K0 can be determined by in situ measurements or be estimated by relations more or less empirical. In the case of a semi-infinite solid mass subjected to an external constraint on its higher edge or to its actual weight, the theory of linear elasticity provides a value of K0 according to Poisson's ratio:*

*K0 =*

*1-*

*Two methods were tested with Code\_Aster to initialize the constraints in the ground boxing:*

- realization of a calculation (order STAT\_NON\_LINE) with a fictitious material equipped with one Poisson's ratio allowing to obtain desired the K0 report/ratio. This calculation is carried out on model which takes again all the grid of the study (for example, the model called GROUND in preceding chapter). In this case, K0 1 (case of linear elasticity). There are the numerous ones case where K0 1 (if the ground is subjected to tectonic constraints, for example). In this case, the following method becomes obligatory;*
- to directly assign the constraints to all the elements of the grid by the order CREA\_CHAMP (option: OPERATION = "AFFE");*

*The first solution requires to define a fictitious material and to implement a calculation moreover. However, if the loading is the actual weight (what is not the case of the case-test only us let us propose), this method appeared at the same time intuitive to us and simple. In the case of a field of constraints uniform, the use of CREA\_CHAMP is unquestionably the most interesting method: it saves time computing and its call is even simpler. For distributions of more complex constraints, CREA\_CHAMP also functions but we did not use it (it paragraph [§ 3.5.3.1] of documentation [U4.72.04] B1 index gives an example adaptable to our problem).*

### **4.3 How to calculate the nodal reactions at the edge of the “future one” gallery?**

To calculate the nodal reactions at the edge of the gallery, it is necessary to block this part of grid. This operation should not generate nonphysical constraints by incompatibility with the loading applied at the time of the phase of initialization. A possibility offered consists to impose the same loading as at the time of the initialization of the constraints by blocking the nodes of edge of the gallery only during this stage of calculation. This operation is without effect on total result, which remains identical to that of the preceding stage, but the “temporary” blocking of nodes of the edge of the gallery makes it possible to evaluate the nodal reactions there.

Even loading  
that at the stage  
the preceding one  
Blocked nodes  
 $U = 0$

#### **Appear 4.3-a: Blocking of the nodes of the edge of the gallery to calculate there nodal reactions**

Concretely, this relative blocking of the edge of the gallery is possible thanks to option DIDI (for Dirichlet

Differential) of key word EXCIT of operator STAT\_NON\_LINE (Doc. Aster [U4.51.03] F4 index, paragraph [§3.2.2]). The blocking of these nodes applies only to the increment of displacement considered and not on total displacement (one imposes  $U = 0$  and not  $U = 0$ ).

The initial state of this calculation (key word ETAT\_INIT of operator STAT\_NON\_LINE) is defined by the field constraints obtained at the end of the preceding stage.

Once this intermediate calculation carried out, the calculation of the nodal reactions is carried out simply by the call to an order CALC\_NO provided with the option OPTION = “REAC\_NODA”. It is appropriate then of to provide to order CALC\_NO all the loadings having produced the result from which one calculate the nodal reactions, without omitting the loading voluminal if they exist (not taken in count in the examples treated here).

One then builds a vector of loading by the recovery of the nodal reactions (CREA\_CHAMP with the key words TYPE\_CHAM = “NOEU\_DEPL\_R”, NOM\_CHAM = “REAC\_NODA” and OPERATION = “EXTR”). It should be noted that according to the paragraph [§3.1.1] of the user's documentation of

*Code\_Aster [U4.72.04] index B1, the option TYPE\_CHAM = "NOEU\_DEPL\_R" of the order CREA\_CHAMP is in fact without effect here (but nevertheless obligatory from the syntactic point of view), since an extraction is carried out. This vector is then defined by order AFFE\_CHAR\_MECA with key word VECT\_ASSE as a loading for the call following to order STAT\_NON\_LINE (corresponding to the progressive excavation of the gallery). This loading is associated a function (operator DEFI\_FONCTION) describing the evolution of the rate of déconfinement progressively with progression of the digging.*

*Also let us notice that all the nodal reactions are extracted: those which act on the edge gallery as those which act on the other edges of the model. Since these last act on points blocked with all the stages of the calculation of excavation, their injection as loading in the following STAT\_NON\_LINE is without effect on the constraints and the deformations with centre of the structure.*

## **4.4**

### ***How to simulate the creation of a "vacuum" in the solid mass and the installation concrete?***

*Once carried out the calculation of the nodal reactions the question of the "elimination" of the part arises*

*excavated digital model so that its rigidity does not block the convergence of the tunnel. For y to arrive, we adopted two methods [Figure 4.4-a]:*

- *method a: quasi-cancellation of the mechanical properties of the elements located in the zone excavated (example:  $E = 0,0001 \text{ Pa}$ ), then introduction of more realistic properties at the time of pose supporting or coating. This method makes it possible to simplify the file of order Code\_Aster and gives correct results for the simple case that we have studied (small circular gallery, excavated in only one section in an elastic solid mass). For to undertake more elaborate studies where the digital processing could be affected by presence of element with very low rigidity, it seems nevertheless preferable to us to rest on following method;*
- *method b: initialization of the constraints directly by creation of fields at the points of Gauss resulting from a calculation concerning a preceding stage.*

*Method A*

*Method B*

*Ground*

*“Vacuum”*

*Concrete*

*1*

*2*

*3*

#### ***Appear 4.4-a: Various principles of modeling to simulate déconfinement solid mass***

*Other methods which we did not test can undoubtedly be applied to the problem studied (as the creation of double nodes at the borders between materials which make it possible to bind or not two structures).*

#### **4.4.1 Method**

##### **With**

*Method A does not call for a particular observation: it is enough to affect characteristics very weak mechanics with the meshes becoming “empty” during calculation of déconfinement.*

*One proceeds in two times:*

- a first order STAT\_NON\_LINE, which makes it possible to reinject the made up loading vector of the nodal reactions and boundary conditions. “Empty” meshes thus correspond to a very soft material;*
- a second call to STAT\_NON\_LINE which introduces supporting or the concrete pavement by assigning to the corresponding meshes realistic characteristics for such a material.*

*With each call, the initialization of calculation takes again the entirety of the fields resulting from preceding calculations (operand EVOL\_NOLI for key word ETAT\_INIT).*

#### **4.4.2 Method**

##### **B**

*This procedure is based on the sequence of several models (with the Code\_Aster direction). Calculation be carried out by copying certain fields from one model to another.*

*The fields to be assigned to the model corresponding at the B-3 stage of [Figure 4.4-a] are formally linear combination of two fields:*

- fields resulting from the preceding stage of calculation (B-2) and which relates to only the model corresponding to the solid mass of private ground of the excavated zone;*
- fields assigned to the elements of the group of mesh which represent the voussoirs in concrete, in the model which includes/understands the solid mass and the gallery lining. In our case, these fields must be initialized to 0 in B-3. For that, one can for example affect one null weight with their contribution in the linear combination. Thus these fields can in fact to be obtained by an intermediate calculation without real physical significance, for example the simple application of the boundary conditions.*

*One uses order CREA\_CHAMP with the option ADZE to assign to the points of Gauss third models the linear combination of fields resulting from preceding calculations.*

## **4.5**

### **Summary of the methods suggested**

*To initialize the constraints, one can call upon two methods:*

- *Méthode I: to make a calculation (call to STAT\_NON\_LINE) on fictitious material;*
- *Méthode II: to create the stress field wished by CREA\_CHAMP.*

*To simulate the digging and the installation of the voussoirs, there are the choice between:*

- *Méthode a: which consists in mechanically affecting “flexible” characteristics very in the excavated zone;*
- *Méthode b: which makes the use of several models which are connected and which is more near to the physical reality of the modelled structure, materials appearing and disappearing by activation from one model to another.*

*A synthetic flow chart is proposed in [§Annexe2].*

## **5** **Examples of command files**

*This part presents examples of structures of command file Code\_Aster concerning a circular excavation in infinite and elastic medium linear, within the framework of a study purely mechanics (not of coupling THM).*

*Three calculation cases are presented in this part:*

- an excavation without supporting with initialization by a bearing calculation on a fictitious material to obtain the stress field wished (method I);
- an excavation with supporting, initialization of the constraints by a call to CREA\_CHAMP and followed method A for déconfinement and poses it voussoirs (methods II + A);
- an excavation with supporting, initialization of the constraints by a call to CREA\_CHAMP and followed method B for déconfinement and voussoirs (methods II + B) poses it.

For cases 2 and 3, the scenario of digging is as follows: excavation, déconfinement to 50% (= 0,5), poses voussoirs of 30 cm thickness and end of déconfinement. These two cases are the object of case-test of validation of Code\_Aster (implemented planned for the beginning of 2003).

## 5.1

### **The dealt with problem**

The geometry of the grid is listed in the paragraph [§4.1]. It contains 8477 nodes and 3304 elements. The ray of the gallery is 1,50 meter, the thickness of concrete is 0,30 meter and the grid is a square of 20 meters of with dimensions. The other data are summarized in the following table.

### ***5.2 Case n° 1: excavation without supporting with initialization of constraints by a calculation and “softening” of the elements “excavated”***

*This example is relatively simple: it is a question of simulating an excavation without installation of supporting,*

*with déconfinement total at the edge of the gallery. One thus uses one model for all calculation.*

*The initial state is generated by a calculation (STAT\_NON\_LINE) which relates to the whole of the grid. properties of the elements are affected according to the state of stresses which one wants to reach (here  $K0 = 1$  thus = 0,4999, the value of 0,5 meaning the incompressibility of the rock not being able to be used).*

*Following calculation relates to the nodal reactions at the edge of the future gallery. It is initialized from constraints resulting from the first call to STAT\_NON\_LINE.*

*The last call to STAT\_NON\_LINE is used to reinject the nodal reactions in a model where mechanical properties of the excavated elements were very strongly weakened (E tends towards 0.). One déconfiner then completely the ground while making tighten these reactions towards 0.*

*The corresponding command file is presented in [Annexe 4].*

### **5.3 Case n°2: excavation with supporting with initialization of constraints by call to CREA\_CHAMP and déconfinement according to method A**

*One follows the scenario of excavation described above. One uses that only one model for all calculation. One order additional STAT\_NON\_LINE allows to introduce the voussoirs with a rigidity realistic after déconfinement of 50%.*

*The corresponding command file is presented in [Annexe 5].*

### **5.4 Case n°3: excavation with supporting with initialization of constraints by call to CREA\_CHAMP and déconfinement according to method B**

*One always follows the scenario of excavation describes higher. This time, three models are used and one intermediate calculation (without physical reality, called “can”) is necessary to transfer them fields of variables from one model to another at the time of the installation of the voussoirs afterwards déconfinement of 50%.*

*The corresponding command file is presented in [Annexe 6].*

## **6 Validation**

***Code\_Aster on an example of excavation in linear springy medium***

*The validation of Code\_Aster rests on the comparison of the numerical results resulting from the cases n°1, 2*

*and 3 listed above with the analytical solution of [Annexe 1]. For each calculation, one presents them results obtained on the level of the keystone and the oven wall of the gallery, in term of constraint radial R, forced orthoradiale and radial displacement U R ([Table 6-1], [Table 6-2] and Table 6-3). [Annexe 7] presents two graphs describing the space evolution of the constraints it length of the vertical axis of the model, with the right of the excavation. The good agreement between analytical solution and*

*numerical results makes that the difference between these curves is hardly visible.*

***Table 6-3: Case n°3, analytical comparison solution/Code\_Aster results for constraints radial and orthoradiale and for radial displacement in A and B***

*The maximum difference between analytical and numerical results is lower than 2%, with share for the constraint radial at the edge of the gallery excavated in the case n°1, where the theoretical value is 0. The validity of calculation is checked by considering that the radial constraint is quite negligible in front of the constraint orthoradiale.*

*Of course, all these variations can be reduced if the grid is still refined.*

## **7** ***As a conclusion: councils and prospects***

*This note proposes a methodology which makes it possible to carry out calculations of excavation using Code\_Aster. Several scénarii of excavation reviewed and several methods are proposed.*

*The method and the software package are validated in the case of a circular gallery, dug in a solid mass infinite constituted by a linear elastic material. Code\_Aster reproduces way completely satisfactory the behavior of such an underground structure, with or without taking into account of supporting and/or of the coating.*

*From the point of view of the user, it seems more practical and more rapid to initialize the constraints by one call to order CREA\_CHAMP rather than by a calculation on fictitious material.*

*If one seeks to model a purely mechanical behavior and if the phasage of the excavation is relatively simple, to work with only one model appears to be the easiest method. It is enough to assign very weak material properties to the meshes becoming "empty". In the cases more complicated, the implementation of several models used successively can prove more reliable from the point of view of implementation the practical (error of modeling) and from the numerical point of view (miscalculation), in spite of the intermediate procedures of transfer of the fields (forced, displacements, pressures, temperatures, variables intern...) from one model to another.*

*A later stage of validation of Code\_Aster could be done on the linear coupled problems (THM in saturated and elastic medium) or coupled and/or nonlinear (being connected model CJS 1 with model of Mohr Coulomb, short-term excavation in not drained to compare with [bib3]).*

**S**

*The difficulty of the calculation of the rate of refund of energy comes from derivation compared to the field*

*of an integral depending on this same field. A rigorous method is the method théta, which is a Lagrangian method of derivation of the potential energy. It consists in introducing one field and to consider transformations  $F: MR. M + (M)$  of the area of reference in a field which corresponds to propagations of the crack. These transformations do not have to modify the edges of the field except the bottom of crack.*

*This method is detailed in [bib38] and the use of the field théta in Code\_Aster is described with [§2.2].*

**S plane**  
**E**

**1.2**  
**Formulation of the functionalities of breaking process in**  
**Code\_Aster**

**1.2.1 Rate of refund of energy G**

*With the method théta, the rate of refund of energy G is solution of the variational equation:*

**G**  
**(S) (S) m (S) ds = G ( ),**  
**O**

where  $m$  is the unit normal at the bottom of crack located in the tangent plan at and returning in  $O$ , and where  $G()$  is defined by the opposite of derived from the potential energy  $W(U)$  with balance by report/ratio with the initial evolution of the bottom of crack:

$$D W(U) = -$$

$$D = 0$$

One notes the conditions to fill by the field (see [§2.2.1]).

In dimension 2, the bottom of crack is brought back to a point, and one can choose a field of such left that the variational equation is brought back to  $G = G()$ .

In dimension 3 dependence of  $G()$  with respect to the field on the bottom of crack is more complex. In Code\_Aster, one can calculate:

· the total rate of refund  $G$  corresponding to a uniform progression of the crack (order `CALC_G_THETA` [U4.82.03]). The user must choose a unit field  $\theta$  with vicinity of the bottom of crack checking  $(S) m(S) = 1, S$  and then:  $G L = G(S) ds = G()$

where  $L$  is the length of the bottom of crack,

## 1.2.2 Coefficients of intensity of constraints K1 and K2 deduced from the calculation of G.

In linear thermoelasticity, the rate of refund of energy  $G$  is a symmetrical bilinear form of field of displacement  $U$ :  $G = G(U, U)$ . By using the method *théta*, the bilinear form  $G(,)$  associated  $G$  is defined by:

$1$   
 $B$

$B$

$G(U, v) =$

$(v$   
 $) +$   
 $(U$   
 $) - B(U, v) \text{ div } D$   
 $2 U$

$v$

while limiting themselves at the end traditional and while noting:

$($   
 $1$   
 $1$   
 $(U))$   
 $(U) = (U) : : (U) = B(U, U)$   
density of energy elastic:  
 $($

$2$

$2$

the tensor of elasticity,

$B$  the symmetrical bilinear form defined by:  $B(U, v) = (U) : : (v)$

In the method established in Code\_Aster (order `CALC_G_THETA [U4.63.03]`), for to uncouple the modes from rupture I and II and to calculate coefficients K1 and KII, one uses this form

bilinear symmetrical  $G$

$(,)$  and regular decomposition of the field of displacement  $U$  in parts  $U$  and singular  $U$ :

***U2.05.01-A Page***

***: 7/52***

### ***1.2.3 Coefficients of intensity of constraints K1, K2 and K3 obtained by extrapolation field of displacements.***

***For a plane crack in an elastic, homogeneous and isotropic material, one can also reach with the values of K1, K2 and K3 by extrapolation of the jumps of displacements on the lips of this fissure (order POST\_K1\_K2\_K3).***

***Contrary to the preceding approach (calculation of  $K_i$  by the bilinear form of the rate of refund of energy), one can thus calculate these coefficients in axisymmetric geometry and 3D and reach K3 coefficient. For each coefficient of intensity of constraint, method, less precise than method G\_THETA [R7.02.01], provides two values framing the solution. One can however be done an idea of the precision of the results by recomputing G by the formula of Irwin, starting from the values of K1, K2 and K3, and by comparing this value with that obtained with G\_THETA. Precision of results is clearly improved if elements touching the bottom of crack (quadratic elements) nodes mediums located at the quarter of the edges have.***

### ***1.2.4 Propagation***

#### ***Lagrangian***

***It is possible with Code\_Aster to calculate the rate of refund of energy for different lengths of crack (in 2D and 3D) by using only one grid representing a length of crack fix reference. These developments are available in linear elasticity, for the elements of continuous medium 2D and 3D, in the situations where the variations of geometry do not affect the edges charged.***

***Any calculation using this method requires, to ensure the passage of the real field studied area of reference, the preliminary creation of a field  $\theta$ , using order CALC\_THETA [U4.82.02]. The formulation developed in Code\_Aster does not take account of the terms***

*thermics, of the loadings on the lips of the crack nor of the forces of volume in general, except initial deformations which are taken into account in 2D only.*

*For more precise details on this option one will refer to the document [R7.02.04].*

### ***1.3 Field of validity of the functionalities of breaking process in Code\_Aster***

#### ***1.3.1 Model***

*The calculation of the rate of refund of energy  $G$  is valid for modelings of the continuous mediums 2D*

*plane strains or plane stresses (D\_PLAN, C\_PLAN), axisymmetric 2D (AXIS) and 3D (3D).*

*U2.05.01-A Page*

: 11/52

*These loadings can depend on the geometry, the moment of calculation and possibly to apply to the lips of the crack.*

*The loadings not supported by an option are ignored.*

*It is important to note that the only loadings to be taken into account in a calculation of mechanics rupture with the method are those applied to the elements inside the crown (between  $R_{inf}$  and  $R_{sup}$  for a linear thermoelastic behavior or not linear [R7.02.01 §3.3], between the bottom of crack and  $R_{sup}$  for a thermoelastoplastic relation [R7.02.07]).*

*If one makes a calculation in great transformations (key word DEFORMATION = "GREEN" under the key word factor COMP\_ELAS) the supported loadings must be died loads, typically one force imposed and not a pressure [R7.02.03 §2.4].*

### **1.3.5 State initial**

*It is possible to take account of an initial state (either of the initial constraints, or of the deformations initial) for the calculation of the rate of refund of energy. Two possibilities are offered to the user:*

- to define initial deformations with key word EPSI\_INIT in the order AFFE\_CHAR\_MECA (\_F) [U4.44.01] and to recover them under the key word CHARGES in orders CALC\_G\_THETA [U4.82.03] or CALC\_G\_LOCAL [U4.82.04],*
- to recover a stress field or initial deformations resulting from a mechanical calculation (evol\_noli resulting from order STAT\_NON\_LINE [U4.51.03]) with the key word ETAT\_INIT.*

### **1.3.6 Contact**

*The calculation of the sizes of breaking process in Code\_Aster is not valid if there is contact with friction between the faces of the crack. Indeed the calculation of the rate of refund of energy*

*does not take into account the dissipative phenomena.*

*On the other hand if the elements of contact are beyond the crown defined between  $R_{inf}$  and  $R_{sup}$  them*

*calculations of  $G$ ,  $G(S)$ ,  $K1$  and  $K2$  are valid.*

*On the other hand, it is possible for the calculation of  $G$  and  $G(S)$  to only take into account conditions of contact without friction to avoid the interpenetration of the lips of the crack.*

### **1.4 Approach energy the elastoplastic rupture and formulation $G_p$ parameter**

*The traditional global solution presents important limits:*

- the loading must be monotonous,*
- more generally, the loading must be proportional and radial (see chapter [§2.5.2]),*

- *one cannot simulate great propagations,*
- *one cannot take into account a residual stress field (see chapter [§1.3.5]).*

*The application of the global solution apart from its field of validity led to problems of “transferability” of test-tubes with structures.*

*U2.05.01-A Page*

*: 12/52*

*Another approach was then considered with EDF-R & D: energy approach.*

*This new approach was developed, on the one hand, within the framework of the ductile tear [bib57], and,*

*in addition, within the framework of brittle fracture by cleavage.*

*In the case of brittle fracture by cleavage, one leaves the theory of Frankfurt Marigo in elasticity [bib56]. This theory is a generalization of the criterion of Griffith for fragile elastic materials.*

*One applies the principle of minimization of energy, to predict the initiation or the propagation of one fissure of surface  $S$  of a surface created  $dS$ . One defines, starting from elastic energy, a parameter Freezing, rate of refund of energy in elasticity [bib58] by the following formula:*

*Freezing = - [We (dS) - We (0)] /Surface (dS).*

*One extends then this approach to plasticity, by making the assumption that plastic dissipation and dissipation related to the rupture are independent.*

*One can then define a plastic parameter  $G$  [bib58], noted  $G_p$ , like a rate of refund of energy in plasticity incremental [bib58] by the following formula:*

*$G_p = - [W (dS) - W (0)] /Surface (dS)$*

*where  $W$  is total energy (free energy + energy of work hardening + plastically dissipated energy).*

***But one finds oneself then confronted with 2 paradoxes of the theory of Griffith [bib62]:***

- the paradox of Rice,***
- scale effects of the theory of Frankfurt-Marigo induced by the assumption of Griffith.***

***One makes the choice then model the defect in the form of notch and not of crack.  
 One defines a rate of refund of  $G_p$  energy applicable to a crack represented in notch, in being based on the formulation of Frankfurt-Marigo and mechanics damage continues, with the help of some additional assumptions.***

***Note:***

***Another alternative consists in being directed towards a theory of Frankfurt-Marigo based on one other models that that of Griffith, like that of Barenblatt.***

***It is supposed that this notch with the shape of a cigar, the bottom of notch ( ) being represented by a half-circle of ray  $R$ . the zone corresponding to the propagation of the notch is noted  $Z_e(L)$  (damaged Zone) and depends on  $L$ , outdistances propagated, in accordance with the figure below:***

***$Z_e(L)$***

***notch***

***$L$***

***( ): melts of notch***

***The  $G_p$  parameter is defined by the following formula:***

***$G_p =$   
we  $dS$***

***·  
[  
max (  
( . )) / ]***

***Notch ( )***

***$L$***

***$L$***

**L**

*where  $W_e$  is elastic energy.*

*This parameter makes it possible to predict:*

- *progressive propagation of the notch (when the maximum is obtained for  $L = 0$ )*
- *brutal propagation of the notch (when the maximum is obtained for  $L = 0$ ).*

*One evacuates in this case the 2 paradoxes of the theory of Griffith.*

*One can use  $G_p$  to analyze situations of brittle fracture per cleavage, when the  $G_{theta}$  approach is not valid. They can be problems with:*

- *discharges [bib59],*
- *loadings nonproportional,*
- *residual stresses,*
- *effect small defect [bib60], [bib61].*

*One introduces the implementation of the calculation of  $G_p$  in Code\_Aster in the chapter [§ 2.5.2.3] and one*

*illustrate this approach on an example in the chapter [§3.4].*

**2**

**Methodology and recommendations of use**

**2.1**

**Grid of the fissured structure**

### **2.1.1 Tool for grid of fissured block**

*Maillor GIBI comprises a parameterized automatic procedure which makes it possible to conceive grids of blocks fissures in 3D. This procedure was developed by EDF-R & D and was validated to ensure the good quality of the grid. One obtains a grid with the format GIBI which can recognize Code\_Aster (order PRE\_GIBI). The user informs a certain number of parameters geometrical (dimensions of crack, cuts block,...) or topological (modeling of the basic torus of crack in crowns, sectors and sections, déraffinement, a number of elements,...) and software generate a block fissures, which can then be integrated in another structure. The user has indicators of quality of grid to adjust the parameters as well as possible.*

### **2.1.2 Methodology**

*Quality of the grid depends numerical quality on the results resulting from mechanical calculation (displacements and constraints) and by consequence of the quality of the sizes in mechanics of rupture. In the presence of a crack it is thus necessary to refine in the vicinity of the bottom of crack to collect with better singularities. But it is not necessary to refine exaggeratedly: interest of the method théta is to utilize the singular terms on elements between  $R_{inf}$  and  $R_{sup}$  and not on those with vicinity of the bottom of crack (except for a calculation in thermo-elastoplasticity, for this case private individual to refer to [§2.5.2]).*

*Calculations of the sizes of breaking process are valid for linear elements or quadratic, but it is strongly advised to use quadratic elements, in particular in 3D. The calculation of these sizes indeed requires to determine with a good approximation them deformation and stress fields which strongly vary in the vicinity of the bottom of crack. However, with an identical number of nodes, the quadratic elements give better results than linear elements, undoubtedly because they are ready to represent this type of variation. Let us add that in 3D, it is necessary to carry out a compromise between a sufficient refinement in bottom of crack on the one hand, and a reasonable size of problem on the other hand. The quadratic choice of elements contribute to carry out such a compromise.*

*A radiant grid in bottom of crack is not obligatory: the rays  $R_{inf}$  and  $R_{sup}$  are not dependent with the grid and the crown can be “with horse” on several elements. Nevertheless practice show that a radiant grid in bottom of crack gives good numerical results. The radiant grid has in particular the advantage of making it possible to impose a constant cutting according to the polar angle, around the bottom of crack, and in the immediate vicinity of this one, cutting well adapted to the asymptotic representation of the fields in bottom of crack. Indeed, this variation according to the polar angle does not depend on the distance from the point considered at the bottom from crack.*

**:**

**U2.05.01-A Page**

**: 14/52**

**In the case of the calculation of the coefficients of intensity of constraint by the method of extrapolation of jumps of displacements on the lips of this crack (order `POST_K1_K2_K3`), it is strongly advised to position the nodes mediums of the quadratic elements concerning the bottom of crack with quarter of the edges (grid of the type “`BARSOUM`”). Thus dependence in `R` of the field of displacement is represented better and the quality of the results is improved. Values of `Ki` coefficients obtained by this method tend towards those deduced from the calculation of `G` (`CALC_G_THETA_T` option `CALC_K_G`) with the refinement of the grid around the bottom of crack.**

### **2.1.3 Estimators**

**errors**

**To assess the quality of the grid it is advised to carry out an elastic design and to use them estimators of errors of discretization: estimators of errors of `ZHU-ZIENKIEWICZ` in elasticity 2D [`R4.10.01`] or the estimator of error by residue [`R4.10.02`].**

**These estimators are established in Code\_Aster in order `CALC_ELEM` [`U4.81.01`]. They are activated starting from the following options: `ERRE_ELEM_NOZ1` for `ZZ1`, `ERRE_ELEM_NOZ2` for `ZZ2` and `ERRE_ELGA_NORE` for the estimator in residue by element.**

## **2.2**

**Introduction of the field *thé*ta**

### **2.2.1 Definition of the field *thé*ta and conditions to respect**

The field  $\theta$  is a field of vectors, definite on the fissured solid, which represents the transformation field during a propagation of crack. It is pointed out that the rate of refund of energy  $G$  is solution of the variational equation:

$$\int_{(S)} \mathbf{m} \cdot d\mathbf{s} = G,$$

where  $\mathbf{m}$  is the unit normal at the bottom of crack located in the tangent plan at (i.e. tangent in the plan of cracking in 3D or the lips of the crack in 2D) and returning in. One notes conditions to fill by field  $C_i$  below:

$\mathbf{m}$

The transformation should modify only the position of the bottom of crack and not the edge of the field. field must thus be tangent with (in particular lips of the crack), i.e by noting  $\mathbf{N}$  normal with:  $\mathbf{N} = \mathbf{m}$

0

The field must be locally in the tangent plan with the lips of the crack and in normal 3D with the edge to which it belongs. This corresponds to the direction of propagation of the crack.

The field must also be continuous on.

Quantity.  $\mathbf{m}$  represents the normal speed of the bottom of crack.

### **2.2.2 Choice of the field $\theta$ in Code\_Aster**

**Because of the singularity of the field of displacement, one uses fields.  $m$  constant with vicinity of the bottom of crack, thus cancelling in this vicinity the singular terms**

-  
**in  $G$  ( $\cdot$ ).  
 $\mu_i, p, K$   
 $K, K$**

**The field  $\theta$  is defined in the following way: in each node of the bottom of crack, one is given 2 rays  $R$  ( $S$  and  $R$  ( $S$ . In on this side  $R$  ( $S$  the module of the field  $\theta$  is constant, with beyond it is**

**inf  
)  
sup  
)  
inf  
)**

**no one and it are linear between the two.**

**$R$  sup  
 $0$   
 $R$   
 $N$   
inf  
  
 $0$   
 $0$   
 $R$ inf  
 $R$  sup**

**The construction of the field  $\theta$  is described precisely in [R7.02.01]. It is established in order  $CALC\_THETA$  in 2D and 3D for the calculation of the total rate of refund  $G$ , and in order  $CALC\_G\_LOCAL$  for the calculation of the local rate of refund  $G$  ( $S$ ).**

**In 2D and axisymmetric the bottom of crack limits itself to a point. The user defines:**

**O**· *the rays  $R$  and  $R$ ,**inf**sup*· *the module in bottom of crack,***O**· *direction of propagation of the crack  $Mr$ .***In 3D the user defines:**· *the rays  $R$  ( $S$  and  $R$  ( $S$ ,**sup*

)

*inf*

)

· *directions of propagation of the crack only at the ends of the bottom of crack**(key words  $DTAN\_ORIG$  and  $DTAN\_EXTR$  in order  $DEFI\_FOND\_FISS$  [U4.82.01]),*· *the topology of the bottom of crack: opened or closed according to if the crack is emerging or not,*· *the module in bottom of crack (only for the calculation of  $G$  total if not  $P$* **O***fields  $I$  necessary to the resolution of the variational equation and the calculation of  $G$   $S$* *( ) are**calculated automatically according to the family of functions of selected interpolation: Lagrange or Legendre, to see [§2.4]).**The directions of the field  $\theta$  except ends are calculated automatically starting from the lips of fissure, but the user can possibly define them itself by using key word  $DIRE\_THETA$ , to see [§2.2.3].***The field is then built so that:** $(R(S)) = 0$ if  $R(S) R(S)$ *sup* $(R(S)) = m$ if  $R(S) R(S)$ **O***inf* $R - R$  $(R(S))$ *sup*

***Problem of the choice of  $R$  and  $R$***

***: The calculation of the sizes of breaking process is***

*inf*

*sup*

*independent of the choice of the crown of integration, i.e. choice of  $R$  and  $R$ . Nevertheless it*

*inf*

*sup*

*is preferable to comply with some rules:*

*· never not to take  $R$*

*= 0 or too small compared to dimensions of the problem because them*

*inf*

*singular displacements are badly calculated in the vicinity of the bottom of crack (valid also in 2D),*

*· in 3D it is necessary to find a compromise between  $R$  not too small and  $R$  not too large. Indeed if*

*inf*

*sup*

*one analyzes the algorithm of construction of the field  $\theta$  (see [R7.02.01]), one notes that to know the direction of the field  $\theta$  in an unspecified point of the solid, it is necessary to project this point on the bottom of crack (i.e. to determine the X-coordinate of the basic point fissures it nearer) and to associate the same direction to him. If one considers a point too far away from the bottom*

*of crack, it may be that the algorithm of research of the basic point of crack nearest give an “erroneous” point: the direction of the field  $\theta$  is badly calculated, with the direction where it*

*does not correspond to the propagation of awaited crack.*

*Solutions:*

*· to check by visualizing the grid that, for the  $R$  chosen, one is not likely to have points*

*sup*

*“badly” projected,*

*· to take several crowns to check the invariance of  $G$ , preferably which are followed*

*[R1, R2], [R2, R3], [R3, R4],...*

## **2.3**

**Standardization of the total rate of refund  $G$  in Code\_Aster**

### **2.3.1 2D forced plane and plane deformations**

**In dimension 2 (plane constraints and plane deformations), the bottom of crack is tiny room to a point and**

**the value  $G$  () resulting from order CALC\_G\_THETA is independent of the choice of the field:**

$$G = G (),$$

### **2.3.2 Axisymetry**

**Into axisymmetric it is necessary to standardize the value  $G$  () obtained with Aster:**

**$l$**

$$G =$$

$$G ()$$

**$R$**

**where  $R$  is the distance from the bottom of crack to the axis of symmetry [R7.02.01, §2.3.3].**

### **2.3.3 3D**

**In dimension 3, the value of  $G$  () for a field given by the user is such as:**

$$G () = G (S) (S) m (S) ds$$

**$O$**

**In order CALC\_THETA [U4.82.02], the user defines the direction of the field in bottom of fissure. By defect, it is the normal at the bottom of crack in the plan of the lips. By choosing one unit field in the vicinity of the bottom of crack, one  $a$ :**

$$(S) m (S) = 1$$

**and:**

$$G () = G (S) D$$

**$O$**

*Either  $G$  the total rate of refund of energy, to have the value of  $G$  per unit of length, it is necessary to divide the value obtained by the length of the crack  $L$ :*

$G () = G L$   
*in 3D*

### *2.3.4 Symmetry of the model*

*Not to forget to multiply by 2, values of the rate of refund of energy  $G$  or  $G (S)$  if one model that half of the solid compared to the crack (or to specify the key word SYME\_CHAR = "SYME" or "ANTI" in the orders concerned).*

## **2.4.2 Methods of smoothing of G and Théta: polynomials of Legendre, functions of form nodes**

*In Code\_Aster, one chose two families of bases (cf [§2.2]):*

· *polynomials of LEGENDRE S of degree J (0*

*J ()*

*J 7),*

· *functions of form of the node K of: S (1*

*)*

*K ()*

*O*

*K NNO = a number of nodes of O*

*(of degree 1 for the linear elements and of degree 2 for the quadratic elements).*

*G S*

*() is broken up:*

· *is according to the polynomials of LEGENDRE:*

*LISSAGE\_G = "LEGENDRE"*

· *is according to the functions of forms of the nodes of the bottom of crack:*

*LISSAGE\_G = "LAGRANGE"*

· *is according to the functions of forms of the nodes of the bottom of crack with simplification of stamp to reverse:*

*LISSAGE\_G = "LAGRANGE\_NO\_NO"*

*I (S) are broken up:*

· *is according to the polynomials of LEGENDRE:*

*LISSAGE\_THETA = "LEGENDRE"*

· is according to the functions of forms of the nodes of the bottom of crack:

LISSAGE\_THETA = "LAGRANGE"

Attention, all the combinations between the families of functions of smoothing for G and THETA are not authorized:

G S

() LEGENDRE G S () LAGRANGE G S () LAGRANGE\_NO\_NO

I (S) LEGENDRE

·

not not

I (S) LAGRANGE

·

·

·

**Théta method: Legendre/G: Legendre:** the resolution of the linear system gives:

NDEG

G (S) = G (J

)

J (S)

j=0

**Théta method: Lagrange/G: Legendre:** one is reduced to the resolution of the linear system to NNO equations and with NDEG +1 unknown factors:

NDEG

I

S

S dS G

G

, I I, NNO

J () I ()

=

=

J

()

j=0

O

In this case, one must have  $NDEG \leq NNO$ , that is to say  $NDEG \leq \min(7, NNO)$  where  $NNO$  is the number of nodes of the bottom of crack.

$J() I()$

$J$

=

$()$

$j=0$

O

*Simplified method known as LAGRANGE\_NO\_NO for smoothing of  $G$  consists with diagonaliser the matrix thus obtained by summation of the horizontal terms.*

### **Remarks and councils of use:**

- *The user does not give a field  $\theta$ , fields  $I$  necessary to the calculation of  $G(S)$  are calculated automatically according to the method specified in order CALC\_G\_LOCAL [U4.82.04].*
- **Choix of the maximum degree of the polynomials of Legendre:** *this choice depends on the number of nodes in bottom of crack. If one has a low number of nodes (ten) it is useless of to take a degree higher than 3 (one conceives easily that the results are poor if one try to find a polynomial of degree 7 passer by by 10 points). Beyond a score of nodes in bottom of crack one can use degrees going up to 7. The experiment shows that the choice of a degree equal to 5 gives good results in the majority of the cases.*
- **Choix of the method:** *it is difficult to give a preference to one or the other method. In principle both give equivalent numerical results. Nevertheless method  $\theta$ : Lagrange is a little more expensive in time CPU than the  $\theta$  method: Legendre. For the first calculation, the use of the two methods and the comparison of the results, allows to consolidate the validity of the model. If the bottom of crack is a closed curve, problems of continuity of the solution at the arbitrarily selected point like X-coordinate curvilinear origin prohibit the use of the polynomials of Legendre. If the bottom of crack were declared "closed" in DEFI\_FOND\_FISS [U4.82.01], one must use the functions of form (Lagrange) to describe the functions  $G$  and  $\theta$ .*
- **Problème of nonthe respect of symmetry:** *if one models only half of the solid by report/ratio with the crack, one must in theory have a curve  $G(S)$  whose slope of the tangent is null with the interface of symmetry. This is not respected by the two methods. Values  $G(S)$  obtained at the ends of the bottom of crack must always be interpreted with prudence, especially if the crack is emerging in a nonperpendicular way (see [§2.2.3]).*
- **Problème of the oscillations** *of the solution with smoothing of  $G$  by the polynomials of Legendre, in particular if  $G(S) = 0$  or constant. If one tries to interpolate a constant function by one polynomial of raised degree, one expects this problem.*

## 2.5 Calculation of $G$ for a non-linear problem

*The essential problem in the nonlinear situations comes from the difficulty in separating them various energy contributions. It is necessary to consider two very distinct classes of problems:*

- that where, in spite of nonthe geometrical linearities or of behavior, one can exhiber one potential for the interior and external actions (nonlinear elasticity or hyperelasticity),
- that where such a potential does not exist (thermo-elastoplasticity).

**I. DEBOST, G. DEBRUYNE, Y. WADIER, E. SCREWS** Key

:

U2.05.01-A Page

: 21/52

*For the first class, one can extend the criterion of Griffith by using the potential energy to balance, and to calculate the rate of refund of energy as in linear thermoelasticity.*

*For the second class of problem, the essential difficulty comes owing to the fact that dissipation is not only due to the propagation of the crack itself. One cannot distinguish which share any more restored energy is used for the propagation and which share is directly used by another dissipative phenomenon (plasticity in fact).*

### **2.5.1 Nonlinear thermoelasticity [R7.02.03]**

#### **2.5.1.1 Not linearity of behavior**

*The relation of nonlinear elastic behavior is described in [R5.03.20]. It should be noted that the law elastoplastic of Hencky-Von Put (isotropic work hardening) in the case of a radial loading and monotonous is equivalent to the non-linear elastic law. Material hyperelastic A a behavior reversible mechanics, i.e. any cycle of loading does not generate any dissipation. The EC fact the relation of behavior of material derives from the free potential energy and one can give one feel at the rate of refund of energy within the framework of the energy approach of Griffith.*

#### **Geometrical 2.5.1.2 Not linearity**

*One extends the relation of behavior to great deformations, insofar as it derives from one potential (hyperelastic law). This functionality is started by the key word DEFORMATION =*

**“GREEN” in orders  $CALC\_G\_THETA$  [U4.82.03] and  $CALC\_G\_LOCAL$  [U4.82.04].**

*The behavior of the solid is supposed to be hyperelastic, namely that the tensor of deformations of Green-Lagrange  $E$  is connected to the field of displacement  $U$  measured compared to the configuration of reference by:*

$$O$$

$$I$$

$$E(\mathbf{U}) =$$

$$(U + u + u U$$

$ij$   
 $I J$   
 $J I$   
 $I K$   
 $K J$ )

2

,

,

,

,

*and that the relation of behavior derives from the free potential energy ( $E$ ):*

$S$

=

$ij$

$E$

$ij$

*$S$  being the tensor of the constraints of Piola-Lagrange called still second tensor of Piola-Kirchoff*

*Such a relation of behavior makes it possible in any rigour to take into account the large ones deformations. However, one confines oneself with great displacements and great rotations, but one remain in small deformations. That to ensure the existence of a solution and to be identical to one elastoplastic behavior under a monotonous radial loading [R5.03.20 §2.1].*

### **2.5.2 Thermo-elastoplasticity [R7.02.07]**

*The field of validity of the calculation of the rate of refund of energy is limited to the thermoelastic framework*

*linear or non-linear. To deal with the elastoplastic problem, two solutions are possible:*

- to bring back itself to a non-linear thermoelastic problem with restrictive assumptions,*

· *to use another formulation, like that of the energy approach.*

*Instruction manual*

*Author (S):*

*I. DEBOST, G. DEBRUYNE, Y. WADIER, E. SCREWS* *Key*

*:*

*U2.05.01-A* *Page*

*: 22/52*

*2.5.2.1 Equivalence enters a nonlinear thermoelastic problem and a thermo problem elastoplastic*

*The relation of nonlinear elastic behavior makes it possible to deal with the problems of breaking process by approaching the thermoelastoplastic behavior. In the case of one monotonous radial loading, it makes it possible to obtain strains and stresses of structure similar to those which one would obtain if the material presented an isotropic work hardening.*

*The use of the indicators of discharge and loss of radiality makes it possible to be ensured of equivalence laws of behavior.*

*But conditions of loadings proportional and monotonous, essential to ensure coherence of the model with actual material, lead to important restrictions of the field of capable problems being dealt with by this method (thermal in particular can lead it to local discharges).*

*2.5.2.2 Formulation of parameter GTP*

*Caution:*

*This formulation results from recent research tasks and parameter GTP does not have yet experimental validity.*

*Within the thermoelastoplastic framework, dissipated energy is distributed on the one hand in rupture*

*and of other*

*leaves in plasticity without it being possible to separately quantify a priori these two types of dissipation. The choice suggested in Code\_Aster consists in deriving total mechanical energy for to obtain a rate of refund of energy, which we will call parameter of rupture GTP. It parameter makes it possible to analyze the nonmonotonous situations of loadings of the defect, for irreversible material behaviors. The relations of thermoelastoplastic behavior are described in detail in the document [R5.03.02].*

*How to make a calculation of GTP in thermoplasticity?*

*· The presence of the key word factor COMP\_INCR, and the key word factor RELATION = "VMIS\_ISOT\_LINE" (or "VMIS\_ISOT\_TRAC") in the orders CALC\_G\_THETA and CALC\_G\_LOCAL indicate that it is necessary to recover the field of displacements U, constraints, and characteristics of elastoplastic material. It is also necessary to recover the fields of the tensors of plastic deformation by operator CALC\_ELEM [U4.81.01].*

*· Modélisation by a notch: The defect must be modelled by a notch and not by a crack.*

*Indeed the formulation of G for a thermoelastoplastic relation is valid only for a notched solid and not for a fissured solid: the principal difficulty in the establishment of this formulation is impossibility of showing the existence of derived from total mechanical energy for a field comprising a crack, and this mainly by the absence of knowledge of the singularities of the fields in plasticity. It is important to note that the terms taken into account in a calculation thermoelastoplastic with the method *théta* are those supported by the elements between the point of crack and Rsup (in opposition to calculation in thermoelasticity not linear where only the terms between Rinf and Rsup are nonnull).*

*Form of possible notch:*

OK  
OK  
NOT

*Instruction manual*

*: 23/52*

*Within the framework of the method théta one considers that the notch is propagated while keeping even form (even if that does not have physical significance for a notch of the type pelletizes).*

*The type of the notch and the ray in bottom of notch do not have an influence on the values of GTP provided that the thickness of the notch is low compared to dimensions of structure. If one models by a pointed notch (traditional crack) the results must to be regarded as forgery (the terms of gradient of the plastic deformations are badly calculated numerically).*

*It is necessary to use a fine grid with quadratic elements in the vicinity bottom of the notch to have reliable results in the cases of discharge.*

***· Difficultés:***

*The smoothness of the grid can lead to important computing times.*

*The modeling of a crack by a notch is delicate in 3D.*

*Which interpretation to make results obtained with this parameter of rupture GTP? With run of the discharge the values of GTP are initially decreasing then then increasing: this is in conformity with the definition of GTP which integrates all accumulation plastic in bottom of defect. If one places oneself on the assumption of Griffith, one could thus to have propagation of the crack in discharge, which is problematic. Like one the problem sees remains open and still requires the validation of a criterion of rupture by experimental tests.*

***2.5.2.3 Approaches energy the elastoplastic rupture and fomulation of the Gp parameter***

***This formulation results from recent research tasks [bib62].***

***One defines a rate of refund of energy in plasticity called Gp applicable to a crack represented in notch, while being based on the formulation of Frankfurt-Marigo for the fragile mediums and on mechanics continues damage (see the chapter [§1.4]).***

***The Gp parameter is defined by the following fomule:***

**$G_p =$   
 $w_e dS$**

**.  
[(  
max  
(. )) /] L**

**L  
Notch (L  
)**

*where  $w_e$  is elastic energy.*

*How to make a calculation of  $G_p$  in thermoplasticity?*

**Grid:**

*The user must carry out a grid of the structure with a defect modelled in the form of a notch and not in the form of a crack. The notch with the shape of a cigar or even the shape of a crack prolonged of a circle in its end.*

**OK  
OK**

**Two types of authorized notches**

**I. DEBOST, G. DEBRUYNE, Y. WADIER, E. SCREWS Key**

**:**

**U2.05.01-A Page**

**: 24/52**

*The bottom of notch ( ) is represented by a half-circle of ray R. the zone corresponding to propagation of the notch is noted Ze (L) (damaged Zone) and depends on L, outdistances propagated, in accordance with the figure below:*

*Ze (L)*

*notch*

*L*

*( ): melts of notch*

*Notch with chips*

*The potential damaged zone is modelled by a stacking of a hundred chips which will allow to make the calculation of energy.*

*The refinement of the grid close to the bottom of the notch must be extremely fine. Indeed, one advises*

*to choose the following geometrical data:*

- the ray of the circle in bottom of notch must be about  $R = 50$  microns, according to material considered,*
- each chip must have a thickness equal to  $1/5 R$  is  $\delta = 10$  microns.*

*One varies the propagated distance L while varying the number of chips considered:  $L = K \delta$ . Only one grid is enough.*

*Note:*

*The Gp parameter does not depend pathologically on the grid.*

*Difficulties:*

*The grid must be parameterized of kind to being able to carry out postprocessings automatically with loops on the kth chip considered.*

*Because of smoothness of the grid, calculations can be rather long and require place memory.*

*The grid of a notch in 3D is rather delicate to realize.*

*Calculation:*

*One makes a calculation with STAT\_NON\_LINE (). The calculation of energy in Code\_Aster is done simply thanks to order POST\_ELEM () with option ENER\_ELAS.*

*It is necessary then for each moment of nonlinear calculation, to calculate  $G_p(K)$ , for each value  $L$  corresponding to  $K$  chips by the formula:*

$$G_p(K) = E_{elas}(K)/(K \text{ delta}l)$$

*One determines then for each moment of calculation, the ligament where the maximum of  $G_p$  is obtained and in particular at the moment corresponding to the rupture.*

### *2.5.3 Indicators of discharge and loss of radiality*

*These indicators make it possible to locate the local discharges and the loss of radiality. Attention with the interpretation of the indicators of discharge and loss of radiality: the value given to time  $T_i$  corresponds to the diagnosis from what occurs between  $T_i$  and  $t_{i+1}$ . Thus, the computed value with the last step of*

*time does not have a direction. The indicator of discharge is negative to indicate a local discharge, and*

*the indicator of radiality is worth 0 for a radial way.*

### *2.5.4 The Councils of use of the law of behavior*

*Calculation in linear thermoelasticity:*

*Before carrying out a calculation into non-linear it is advised to carry out the first thermo calculation linear rubber band and post-to treat the results to have a first idea of about size results.*

### ***Calculation into non-linear:***

***Insofar as it is possible it is preferable to make a thermoelastoplastic calculation and of to compare the results obtained with those of a nonlinear thermoelastic calculation. That allows to make sure that the loading is radial and monotonous, with possibly a certain approximation (use of the indicators of discharge and loss of radiality). If such is not the case, the problem remain open, and one can then be directed worms of postprocessings of the type “approaches local”.***

***Even if nothing prohibits in Code\_Aster to carry out a calculation with a law of behavior and of post-to treat with another law, the results are generally to question and the user must thus to be very attentive on this point.***

***Code\_Aster***

***3.1 Methodology***

***3.1.1 Orders***

***Code\_Aster***

***One presents the principal orders here to be implemented in Code\_Aster Version 6. for to carry out a postprocessing in fragile breaking process. For more precise details on orders concerned, one will be able to refer to the documentation of use.***

**Acquisition of the data of the file of grid: LIRE\_MAILLAGE [U4.21.01]**

*For a grid 3D it is necessary to think as of the generation of the grid of naming the nodes of the bottom of fissure and the meshes of the lips of the crack. The nodes of the bottom of crack must be ordered for to define the direction of course of the curvilinear X-coordinate of the bottom of crack. One can order the nodes of melts of crack with order DEFI\_FOND\_FISS [U4.82.01].*

**The Council:**

*Obligatorily to use quadratic elements (for an elastoplastic problem and strongly advised for a 3D problem).*

*For more details to consult [§2.1].*

**Definition of the model: AFFE\_MODELE [U4.41.01]**

*The modelled physical phenomenon is mechanical (PHENOMENE=' MECANIQUE'). Modeling is chosen among modelings of the continuous mediums 2D plane deformations or plane constraints, axisymmetric 2D and 3D (D\_PLAN, C\_PLAN, AXIS, 3D).*

**Characteristics of material: DEFI\_MATERIAU [U4.43.01] and AFFE\_MATERIAU [U4.43.03]**

*The behavior is either elastic linear (key word factor ELAS or ELAS\_FO) or nonlinear (word key factor ECRO\_LINE or ECRO\_LINE\_FO or TRACTION). Characteristics of materials to define are the modulus Young, the Poisson's ratio, possibly the dilation coefficient thermics and in the nonlinear case elastic limit and the module of work hardening or the curve of traction. These characteristics can depend on the temperature for the calculation of the rate of refund of energy.*

*For the calculation of the stress intensity factors the characteristics must be defined on all materials, including on the elements of edge, because of method of calculation [R7.02.05]. For to ensure itself so it is advised to make a AFFE=\_F (TOUT=' OUI') in the order AFFE\_MATERIAU [U4.43.03], even if it means to use the rule of overload then.*

**Assignment of the mechanical loadings: AFFE\_CHAR\_MECA (\_F) [U4.44.01]**

*The mechanical loadings are those of the continuous mediums. One will take care that the loadings used either supported well by the operators of breaking process (voir§1.3.4) if not they are been unaware of.*

*For a problem where thermics intervenes, one recovers the thermal loading of origin by the word key TEMP\_CALCULEE in order AFFE\_CHAR\_MECA [U4.44.01]. For the possible resolution thermal problem, it is necessary to define the thermal model with AFFE\_MODELE [U4.41.01] ( selected modeling is the same one as that of the mechanical model). The thermal loadings are those of the continuous mediums and are defined with AFFE\_CHAR\_THER (\_F) [U4.44.02]. The resolution is made with THER\_LINEAIRE [U4.54.01] or THER\_NON\_LINE [U4.54.02].*

**Resolution of the mechanical problem: MECA\_STATIQUE [U4.51.01] or STAT\_NON\_LINE [U4.51.03]**

*If the problem is elastic linear, the total operator MECA\_STATIQUE is used who calculates them displacements starting from the model, of the material field, the boundary conditions and the loading. The concept produced by this operator is of evol\_elas type.*

*If the problem is non-linear, the total operator STAT\_NON\_LINE is used who produces a concept of evol\_noli type.*

*:*

*U2.05.01-A Page*

*: 27/52*

*It is possible to use order CREA\_CHAMP (OPERATION='EXTR') [U4.72.04] to recover the field of displacements to the nodes (necessary for the postprocessing of mechanics of rupture). But one can also directly use the concept evol\_elas and evol\_noli in orders of breaking process, by specifying the desired sequence numbers.*

*The Council: For an expensive non-linear calculation in memory and time CPU, it is advised of to constitute a base and to continue the study for postprocessings (in particular in mechanics of rupture). For more details to consult the documents BEGINNING [U4.11.01], CONTINUATION [U4.11.03] and END [U4.11.02]. It is then necessary to be vigilant on the compatibility of the versions of Code\_Aster between two connected executions.*

*Postprocessing in breaking process*

*Definition of the characteristics of the bottom of crack: DEFI\_FOND\_FISS [U4.82.01]*

*This order makes it possible to define:*

- in 2D the node of the bottom of crack and the normal with the crack,*
- in 3D nodes of the bottom of crack and meshes of the lips of the crack.*

*In 2D this order is obligatory only for the calculation of the coefficients of intensity of constraints. In the case of a symmetrical structure where half of the crack is represented, the single one lip must be defined by LEVRE\_SUP. If the crack does not emerge, it is not then of course necessary to define the directions of  $\theta$  at the ends by DTAN\_ORIG and DTAN\_EXTR.*

*Assignment of the field  $\theta$ : CALC\_THETA [U4.82.02]*

*This order makes it possible to affect the field  $\theta$  necessary to the calculation of the rate of refund of energy or of the stress intensity factors. The field  $\theta$  is a field with the nodes defined on all it grid.*

*The user must define the characteristics of the field  $\theta$ :*

- the module (equal to 1. a priori),*
- direction of propagation: equalize with that of the bottom of crack in 2D, calculated automatically in 3D starting from the directions of propagation of the nodes in bottom of crack (these directions are recovered by the concept of the fond\_fiss type produces by the operator DEFI\_FOND\_FISS or by key word DIRE\_THETA),*
- the Rinf rays and Rsup of the crowns surrounding the bottom of crack and used in method  $\theta$ : in 2D the bottom of crack is tiny room to a node and the crowns are circulars. In 3D the rays can be variable with the curvilinear X-coordinate of the bottom of fissure and Rinf, Rsup define two deformed and variable cylinders then surrounding the bottom of crack.*

*This order is not necessary if one carries out a calculation of the rate of refund of energy room: field  $\theta$  is calculated automatically starting from the bottom of crack resulting from DEFI\_FOND\_FISS, of rays Rinf and Rsup and of the method of interpolation defined in order CALC\_G\_LOCAL.*

*Choice of the rays Rinf and Rsup:*

- The choice of the rays Rinf and Rsup is independent of the topology of the grid (even if it is preferable, one is not obliged to have a radiant grid at a peak of crack).*
- Never not to use a definite field  $\theta$  with a ray lower null Rinf. Indeed fields displacements are singular in bottom of crack and introduce results vague in postprocessing of breaking process.*
- In thermo-elastoplasticity, one uses a crack as notch. One will make sure that the ray Rinf inferior is quite higher than the ray of the notch.*
- In 2D the ray higher Rsup can be as large as one wants in condition of course that crown thus defined either contained in the solid.*
- In 3D the problem is more delicate: it is necessary to find a compromise between Rinf not too small (results vague because of the fields of singular displacements evil calculated in bottom of*

**Calculation of the rate of refund of energy room in 3D: CALC\_G\_LOCAL (\_T) [U4.82.04]**

*Order CALC\_G\_LOCAL makes it possible to calculate the rate of refund of energy G in 2D or 3D by the method  $\theta$  in the case of a linear thermoelastic problem or not linear.*

*For this calculation the user must specify obligatorily:*

- the model,*
- the material field,*
- the field of displacements (starting from a field with the nodes or of a result),*
- bottom of crack,*
- the rays Rinf and Rsup defining the crowns surrounding the bottom of crack,*

*and possibly:*

- loading (if the voluminal, surface loading on the lips of the crack or origin thermics),*
- the relation of behavior (by linear defect thermoelasticity),*
- method of discretization of the field  $\theta$  in bottom of crack (per defect method of Legendre, degree 5),*
- plastic deformations (if the behavior is thermoelastoplastic).*

*It will be noted that the field  $\theta$  is calculated starting from the bottom of crack and the rays Rinf and Rsup (useless*

*to use safe order CALC\_THETA for the particular case of the Lagrangian propagation).*

*Order CALC\_G\_THETA also allows the calculation of the rate of refund of energy room with Lagrangian propagation in 3D (option CALC\_G\_LGLO) in the case of a thermoelastic problem linear [R7.02.04].*

**Calculation of energy for the calculation of the rate of refund of energy in Gp plasticity:**

*One uses order POST\_ELEM (), with option ENER\_ELAS. One obtains the calculation of Gp by one*

*post\_traitement manual (see chapter [§1.4] and chapter [§ 2.5.2.3]).*

### **3.1.2 Traps to be avoided**

#### **Grid:**

*In 3D the nodes of the bottom of crack must be ordered.*

*For a thermoelastoplastic problem (parameter GTP and Gp) it is necessary to model the crack by one notch and to use quadratic elements.*

#### **Loading:**

*During a thermal calculation, one should not forget to introduce into the operand CHARGES of CALC\_G\_THETA or CALC\_G\_LOCAL the thermal load of origin.*

*The not supported loadings are ignored. No message of alarm is transmitted, one will refer thus with [§1.3.4] to make sure that the loadings used have a direction in breaking process and are well treated.*

*If the list of the loads comprises more than one load, a loading of comparable nature cannot appear that in only one load. In the contrary case, only the last load is taken into account.*

*If the field of displacement were calculated by a load with a multiplying coefficient different from 1. , one will have, to obtain G corresponding to the good loading, to introduce into the operand CHARGES*

*CALC\_G\_THETA or CALC\_G\_LOCAL the load in question multiplied by this coefficient (see COMB\_CHAM\_NO [U4.72.02] for this problem).*

*If one makes a calculation in great transformations (key word DEFORMATION = “GREEN” under the key word*

*factor COMP\_ELAS) the supported loadings must be died loads, typically one force imposed and not a pressure [R7.02.03 §2.4].*

**Law of behavior:**

**Nothing prohibits in practice to solve the mechanical problem with a law of behavior (in MECA\_STATIQUE or STAT\_NON\_LINE) and to carry out postprocessing with another law of behavior: to avoid.**

**Symmetry of the loading and standardization:**

**In orders CALC\_G\_THETA and CALC\_G\_LOCAL key word SYME\_CHAR makes it possible to indicate if**

**the loading is symmetrical or antisymmetric in the case or one only half of the solid models compared to the crack.**

**This key word is essential if one uses option "CALC\_K\_G" to calculate the factors of intensity of constraints: it makes it possible to assign K2 to 0 if the loading is symmetrical compared to the crack or K1 with**

**0 if it is antisymmetric.**

**It also makes it possible to multiply by 2, the values of the rate of refund of energy G if one does not model**

**that half of the solid compared to the crack.**

**"WITHOUT" "ANTI" "SYME"**

**G GASTER 2.\***

**GASTER 2.\***

**GASTER**

**K1 K1ASTER K1ASTER 0.**

**K2 K2ASTER 0. K2ASTER**

**Caution:**

**Not to forget that in certain configurations, a manual postprocessing is necessary to obtain the standardization of the value of the rate of refund of energy. In particular in axisymmetric, it is necessary to divide GASTER by the distance from the bottom of crack to the axis of symmetry and into**

**3D by the length of the bottom of crack [§2.3].**

**Definition of the bottom of crack and the Rinf rays and Rsup in 3D:**

**When the crack is emerging, to define the directions of the field  $\theta$  well at the ends of the bottom of fissure using key words DTAN\_ORIG and DTAN\_EXTR in order DEFI\_FOND\_FISS [U4.82.01]. See 2.2.2.**

**Attention with the choice of the Rinf rays and Rsup of the crown. See [§2.2.3].**

***Calculation of energy for the calculation of the rate of refund of energy in  $G_p$  plasticity:  
It should be taken care that energy is calculated with sufficient precision because one carries out for  
calculation of  $G_p$  a difference between very small quantities.***

### ***3.1.3 Checks concerning postprocessings of breaking process***

***It is important to have an idea of about size of the results before beginning any calculation  
numerical (simplified model, test of reference, bibliography,...).***

***It is advised to use successively orders  $CALC\_G\_THETA$  or  $CALC\_G\_LOCAL$  with with  
less 3 fields  $\theta$  of different crowns to ensure itself of the stability of the results. In the event of  
important variation (higher than 5-10%) it is necessary to wonder about the good taking into account  
of all  
modeling. This stability is a condition necessary (but not sufficient) for the validity of  
results.***

**3.4**

***Example 3: calculation of  $G_p$  for an elastoplastic problem in 2D***

***One carries out a calculation in breaking process for an elastoplastic problem in 2D deformations plane.***

***One implements the calculation of the  $G_p$  parameter resulting from recent research tasks (see chapter [§ 2.5.2.3]) to highlight “the effect small defect”.***

***Context and objective:***

***Tenacity is a parameter determined in experiments on a test-tube CT fissured in traction, who is supposed to represent the breaking strength of material. But on the test-tubes, the cracks are big sizes compared to the real cases. The effects of triaxiality are important and plasticity weak.***

***On the contrary on real cases, the cracks are smaller sizes, the effects of triaxiality are more weak, and plasticity is stronger. Measured tenacity would be then larger, from where a profit of margins potential. The size of the crack thus has an effect on the measured value of tenacity. It is this effect which is called “effect small defect”.***

***One applies here the energy approach based on the calculation of  $G_p$  parameter to the interpretation of the effect small defect.***

***One considers on the one hand a test-tube SENB with a great defect (SENB1) and on the other hand one test-tube SENB with a small defect (SENB2).***

**3.4.1 Geometry**

***Rectangular plate with small or great defect. One represents only half of the structure.***

**Height plates  $H = 50$  mm**

**Width plates  $L = 420$  mm**

**Spacing between two supports  $S = 370$  mm**

**Cut defect  $a_f = 25$  mm (SEN B1) or 3.8 mm (SEN B2).**

**$L/2$**

**$L_{pilot}$**

**$L_{igr}$**

**$H$**

**$a_f$**

**$L_{appui}$**

**$S/2$**

### **3.4.2 Properties of materials**

**Young modulus:  $E = 208510$**

**Poisson's ratio:  $\nu = 0.3$**

**Traction diagram with nonlinear work hardening (behavior VMIS\_ISOT\_TRAC)**

### **3.4.3 Boundary conditions and loadings**

**One applies the condition of support to  $L_{appui}$   $D_y = 0$ .**

**One applies the condition of symmetry  $dx = 0$  to the ligament of defect LIGR.**

**One charges in displacement out of  $D_y$  on edge LPILOT.**

**3.4.5 Interpretation**

**For large crack (SENBI)**

*This case corresponds to calculation on test-tube CT.*

*One identifies the moment  $T1 = 30$  S corresponding to the arrow with the experimental rupture of 1.21 Misters One*

*determine at this moment  $G$  theta which is stable for various crowns:*

*$G_{theta\ SENB1} = 47.86$*

*One then determines for every moment the ligament where  $G_p$  is maximum and in particular at moment  $T1$ :  $G_p = 0.606$  on ligament 26 for  $dl = 0.26$  Misters.*

*For small crack (SENB2)*

*One determines in this case the moment when  $G_{pmax}$  is worth also 0.606.*

*It is about  $t2 = 80$  S on ligament 16 for  $dl = 0.16$  Misters.*

*One calculates at the moment  $t2$  the value of  $G_{theta\ SENB2} = 153.79$ .*

*One thus deduces an effect from it small defect which is expressed in the form:*

*$(epd)^2 = G_{theta\ SENB2}/G_{theta\ SENB1} = 3.21$  is  $epd = K_{SENB2}/K_{SENB1} = 1.79$*

**Note of modeling of damping mechanics**

## **Summary**

***Linear and non-linear dynamic analyses, for the study of the vibratory response with an excitation in force or moving imposed or for the modal analysis complexes, require to add characteristics of mechanical cushioning to the characteristics of rigidity and mass.***

***One has several traditional modelings, applicable to all the types of finite elements available:***

- the model of viscous damping,***
- the model of damping hysteretic (known as also “structural damping”) for the analysis harmonic of viscoelastic materials.***

***For the analyses using a modal base of real clean modes, it is possible to introduce coefficients of damping modal.***

***1***

***Model of viscous damping***

***The model of viscous damping is most usually used. It corresponds to modeling of a dissipated energy proportional to the vibratory speed:***

***1***

$$1$$
$$ED = vT Cv = C Cu$$

*éq 1-1*

2  
2

*where C is the matrix of viscous damping, with real coefficients.*

*It leads to the traditional equations of the dynamics of the structures:*

$$Driven + Cu + Ku = F (T)$$

*éq 1-2*

*with K stamps rigidity and M stamps of mass.*

*1.1*  
*Viscous damping proportional “total”*

*This modeling, easy to implement, corresponds to:*

$$C = K + M$$

*éq 1.1-1*

*It is currently available, by using operator COMB\_MATR\_ASSE [U4.72.01], after having assembled the matrices of rigidity and mass with real coefficients, but it is of a low utility:*

*• validation of algorithms of resolution,*

· *useless for the industrial studies, because it does not make it possible to represent the heterogeneity of the structure compared to damping (dissipation with the supports or the assemblies). Of more the total identification of the coefficients and is not possible, in modal analysis experimental, that for two Eigen frequencies [f1 f2] distinct; it gives, for Eigen frequencies fi [F, F*

*I  
2] with I = 2 F  
I, a law of evolution of damping  
tiny room of the form:*

*I = I +*

*I*

*1.2  
Viscous damping proportional of the elements of the model*

*1.2.1 Characteristics  
of damping*

*It is possible to build a matrix of damping starting from each element of the model, as for rigidity and the mass.*

*Two functionalities are usable:*

- *the assignment of discrete elements, on meshes POI1 or SEG2, by operator AFFE\_CARA\_ELEM [U4.42.01]. This one makes it possible to define, with several possible modes of description, a matrix of damping for each degree of freedom.*
- *the definition of a characteristic of damping for any elastic material by the operator DEF1\_MATERIAU [U4.43.01] by:*

*AMOR\_ALPHA*

*:*

*[R]*

*AMOR\_BETA*

*:*

*this material being then affected with the meshes concerned.*

*Instruction manual*

### **1.2.2 Calculation of the matrices of damping**

**For all the types of finite elements (of continuous, structural or discrete mediums), it is possible of to calculate the real elementary matrices corresponding to the option of calculation**

**“AMOR\_MECA”, afterwards**

**to have calculated the elementary matrices corresponding to the options of calculation**

**“RIGI\_MECA” and**

**“MASS\_MECA” or “MASS\_MECA\_DIAG”. Each elementary matrix is then of the form:**

**· when material I, of characteristics of viscous damping proportional (I I), is affected with the element elem**

$$celem = I kelem + I melem$$

**· for a discrete element**

$$celem = adiscret$$

**This operation is possible with:**

**mel**

**[matr\_elem\_DEPL\_R] = CALC\_MATR\_ELEM**

**(**

**/**

**OPTION:**

**“AMOR\_MECA”**

**MODEL:**

*Mo*

*[model]*

**CHAM\_MATER:**

*chmat*

*[cham\_mater]*

**CARA\_ELEM:**

*will cara*

*[cara\_elem]*

*);*

*The assembly of all the elementary matrices of damping is obtained with the operator Usual ASSE\_MATRICE [U4.61.22]. It will be noted that one must use same classifications and it even mode of storage that for the matrices of rigidity and mass (operator NUME\_DDL [U4.61.11]).*

*It is noticed that the matrix of damping obtained is, in general, nonproportional:*

$$C \bullet = K + M$$

### *1.2.3 Use of the matrix of viscous damping*

*The matrix C is usable for the direct linear dynamic analysis (key word MATR\_AMOR) with operators of linear dynamic response:*

*• transitory*

*DYNA\_LINE\_TRAN*

*[U4.53.02]*

*• harmonic*

*DYNA\_LINE\_HARM*

*[U4.53.11]*

*It is essential for the modal analysis complexes with the operators of research of the values clean:*

*• by iterations opposite*

*MODE\_ITER\_INV*

*[U4.52.04]*

*• by simultaneous iterations*

**MODE\_ITER\_SIMULT**  
**[U4.52.03]**

*For the analyses in modal base, one must project this matrix in the subspace defined by one together of real clean modes. This operation is possible with the operator PROJ\_MATR\_BASE [U4.63.12]. Let us note that in the case general (C nonproportional), the matrix projected is not diagonal. It remains nevertheless usable (key word AMOR\_GENE) for the calculation of dynamic response in force or imposed in modal space, with the operator of linear dynamic response:*

*· transitory*  
**DYNA\_TRAN\_MODAL**  
**[U4.53.21]**

***· seismic analysis by spectrum of oscillator***

***COMB\_SISM\_MODAL***

***[U4.84.01]***

*Let us note that there is not any tool for automatic extraction of these coefficients, starting from the matrix of damping generalized T C), concept produced by operator PROJ\_MATR\_BASE [U4.63.12].*

**2**  
*Model of damping hysteretic*

*The model of damping hysteretic is usable to treat the harmonic answers of structures with viscoelastic materials. The damping coefficient hysteretic is determined starting from a test under harmonic cyclic loading with the pulsation for which one a relation stress-strain obtains which makes it possible to define:*

*· the energy dissipated by cycle in the form:*

$$E = D$$

*cycle*

*· the YOUNG modulus complexes  $E^*$  starting from the relation stress-strains:*

$$J(T) = \frac{E}{\omega}$$

*and  $\theta = \arctan(\frac{D}{E})$  with  $\theta$  and amplitudes*

*,  $\theta$  phase*

$$E^* = E - jD$$

=  
 $0$   
( $\cos + J \sin$ )

$0$   
 $0$   
where  $E^* = E1 + J E2 = E1 (1+ J)$

$$M \ddot{u} + K * (1 + J) U = F ()$$

*éq 2-1*

*with K stamps real elastic rigidity, M stamps of mass and the coefficient damping hysteretic. Let us note that one often speaks about complex matrix of rigidity.*

2.1  
*“Total” damping hysteretic*

*This modeling, easy to implement, corresponds to:*

$$(- M \ddot{2} + J K + K) U = F ()$$

*éq  
2.1-1*

*It is currently available, by using operator COMB\_MATR\_ASSE [U4.72.01], after having assembled the matrix of rigidity to real coefficients, but it is of a low utility:*

- *validation of algorithms of resolution,*
- *useless for the industrial studies, because it does not make it possible to represent the heterogeneity of the structure compared to damping (dissipation located in particular zones structure treated with viscoelastic materials).*

2.2  
*Damping hysteretic of the elements of the model*

2.2.1 *Characteristics of damping*

*It is possible to build a complex matrix of rigidity starting from each element of the model, as for real rigidity and the mass.*

*Two functionalities are usable:*

*· the assignment of discrete elements, on meshes PO11 or SEG2, by the operator AFFE\_CARA\_ELEM [U4.42.01]. This one makes it possible to define, with several modes of description possible, a matrix of real rigidity for each degree of freedom and one damping coefficient hysteretic to apply to this matrix.*

**AMOR\_HYST:**

*éta*

**[R]**

*· the definition of a characteristic of damping for any elastic material by the operator DEF1\_MATERIAU [U4.43.01] by the key word:*

**AMOR\_HYST:**

## *1 Introduction*

*Treatment in seismic analysis of the problem of the behaviour of buildings posed on flexible foundation*

*require the taking into account of the interaction between the ground and the structure. However, traditional tools for*

*to treat this interaction (PARASOL and CLASSI) authorize only rigid foundations, or even take into account only exclusively homogeneous grounds and foundation rafts of form not unspecified (case of PARASOL). This is why code PROMISS3D, developed at the Central School of Paris, was chained by a procedure established in Code\_Aster to make it possible to model with time of the flexible foundations, the heterogeneous grounds - with an extension particular to the laminated grounds -*

*and of the foundation rafts of an unspecified form, and thus to allow calculations of dynamic interaction with one or several unspecified structures.*

*On the one hand, the modeling of the structure of the building as well as the loadings which are to him*

*applied, is realized with Code\_Aster, and in addition, it is necessary to carry out the analysis constraints*

*dynamic obtained starting from the characteristics of the elements of the structure modelled using this code. It is thus then necessary to constitute an interface between PROMISS3D and Code\_Aster to connect the two preceding operations with the calculation of the linear dynamic evolution of the ground-buildings unit carried out by PROMISS3D.*

*This document has thus as a matter to describe this interface consisted modules of calculation developed around PROMISS3D and by new specific orders of Code\_Aster. One y fact as a preliminary a simplified description of software PROMISS3D, complete and detailed description*

*of its principle being made in the user's manual of PROMISS3D - MISS2D [bib1]. One presents to it the case of standard application of a nuclear small island subjected to a seismic excitation treaty with different*

*case of foundation: rigid or flexible with or without reduction of modes of deformation of the foundation raft.*

2

## *Description and principle of software PROMISS3D*

*Software PROMISS3D makes it possible to deal with the problems of propagation of wave in fields rubber bands or fluids.*

*It uses the geometrical assumption of linearity and behavior: that is to say the equation of Navier (conservation of the momentum) with the law of Hooke in the springy media and the equation of the waves in the fluid environments.*

*This assumption makes it possible to apply a transformation of Fourier compared to the temporal variable*

*for the whole of the fields to be calculated and thus, to operate the resolution in the field of frequencies. The return in the temporal field is carried out in postprocessing by the transformation of Opposite Fourier.*

*Lastly, software PROMISS3D rests on a method of under-structuring: the field of study is broken up into under-fields coupled between them by interfaces. One applies a method to it of resolution multi-fields and only the interfaces between fields require to be with a grid by finite elements of border.*

*The resolution is carried out then on the borders of the under-fields and is founded on knowledge elementary solutions, functions of Green, fields generated in an infinite field by one specific request. One can thus treat the case of the not limited fields, by avoiding any reflexion parasite on fictitious borders truncating the field of study. Moreover, one original extension and economic was brought to the method by the introduction treatment of laminated fields implicitly taking into account various homogeneous layers of a field without having recourse to a grid of their interfaces.*

### ***Principle of the Code\_Aster interface - PROMISS3D***

**3.1**

#### ***Case of the external field in PROMISS3D***

*In the case of one or several buildings subjected to a seismic excitation which one wants to study the interaction ground-structure (ISS), one separates by an interface the field from the “structure” including/understanding the buildings (but also possibly parts of ground not laminated like fill) of the field “ground” (either laminated, or homogeneous or comprising even fluid parts (e.g.: reserve of stopping)) modelled directly by PROMISS3D [Figure 3.1-a].*

***Interface***

***Structure***

***small island***

***Ground layer 1***

***Ground layer 2***

#### ***Appear 3.1-a: Model of interface ground - structure***

*The structure modelled by Code\_Aster is regarded as an external field for PROMISS3D. In this case, one breaks up a displacement in this field on modes which, reduced to the interface, can be null i.e. the dynamic clean modes of the structure on base fixes, or not null, i.e. the static modes:*

***U = has +***

***I***

***B***

***I***

***J***

***I***

The coefficients **have** and **bj** is respectively the factors of participation of the dynamic modes and statics. **M** and **K** are respectively the assembled matrices of mass and rigidity. Then, the writing balance of the field “structure” within the meaning of virtual work provides the following system:

**K**

2

**has**

**dd**

**Kds**

**Mdd Mds**

**F D**

-

=

**K**

**B**

+

**ds**

**Kss**

**Mds Mss**

**F S F**

The matrices **Kdd** and **Kss** are the assembled rigidities projected respectively on the modes dynamic and static: **TK** and **TK**.

The matrices **Mdd**, **Mss** are the assembled masses projected respectively on the modes dynamic and static: **TM** and **TM**.

**Kds** and **Mds** are the link-words or products cross: **TK** and **TM**.

Instruction manual

**$f_d$**  and  **$f_s$**  are respective projections on the dynamic and static modes of the vector forces applied  $F$  to the field “structure”:  **$TF$**  and  **$TF$** .

$F$  represents the action with the sign close to the field “structure” on the interface and can thus be expressed with

to leave the preceding system, by eliminating the factor has, by:  **$F = feq + K^* B$**

with  **$feq$**  the vector of equivalent forces and  **$K^*$**  the matrix of impedance of the field given by:

$$feq = -fs + (Kds - 2 Mds) T (Kdd - 2 Mdd) - 1 fd$$

$$K^* = (Kss - 2 Mss) - (Kds - 2 Mds) T (Kdd - 2 Mdd) - 1 (Kds - 2 Mds)$$

It is shown simply that one can be reduced to the resolution of 2 local problems to obtain  **$feq$**  and  **$K^*$** . Indeed  **$feq$** , solution of the 1st local problem, is the effort applied to the blocked interface when one

apply the forces to the field “structure”. And when, in the 2nd local problem, one imposes displacements of unit static modes  $B$  on the interface without forces applied to the field “structure”, one obtains  **$K^* B$**  like effort applied to the interface.

The resolution is carried out on (S) the interface (S) which must (or must) be with a grid (S) with elements surface directed towards the interior of the field “ground” and on this (or these) interface (S) it must y have between 6 and 10 nodes per wavelength. In the field of the seism one is interested in a beach of frequency going of 0.1 Hz to 30 Hz.

### 3.2 Contents of the interface

The Code\_Aster chaining - PROMISS3D requires the transfer of following information.

**In the Code\_Aster direction towards PROMISS3D, one transfers successively:**

- information concerning the grid of the interface ground-structure (nodes and elements surface) as well as the static modes of interface and the dynamic modes of the structure

reduced to the nodes of this interface and ordered according to its local classification, information on the basis of static and modal dynamic mode independent of local classification: modal masses and rigidities, modal factors of participation and other terms of coupling between the dynamic modes and the static modes and, for each load interns with the structure, projections of the assembled vector corresponding, on static and dynamic modes as well as the multiplicative function of time associated.

**In direction PROMISS3D towards Code\_Aster, one recovers:**

· Of the evolutions of results of displacements, speeds and accelerations generalized (standard "TRAN\_GENE") (T), "(T), " (T) on the one hand, and (T), " (T), " (T) on the other hand, projected respectively

starting from the dynamic modes and static modes. One will be able to then project, then to combine these results on the physical basis:  $U(T) = .(T) + .(T)$ .

In the case of a harmonic calculation one recovers complex evolutions by frequency () and () (of type "HARM\_GENE") before projecting them to produce an evolution of it harmonic on the physical basis:  $U() = .() + .()$ . () and () are always complexes because of the form complexes impedance of ground: K.

### 3.3

#### **Procedure of sequence of the programs**

An automatic procedure was made up in order to encapsulate the programs necessary to Code\_Aster chaining - PROMISS3D.

The user must first of all constitute the data of Code\_Aster for the preprocessing like those to describe the stratifications of the ground in module DOS2M of PROMISS3D in order to calculate

*functions of Green.*

*A first program, **gtaster**, starting from the file result of Code\_Aster, generates the data of PROMISS3D including/understanding: grid of the interface (suffix .mail), calculation data (.in), them impedances of the structure (.ext), loadings on the structure (.cext), data of postprocessing (.post).*

*A second program, **ptaster**, recover the movements of the interface calculated by PROMISS3D in displacements, speeds and accelerations generalized and transmits them to Code\_Aster for post-to treat.*

*It is possible in the same tender successively to launch the programs gtaster, PROMISS3D, ptaster on the central machine of treatment by successive calls to EXEC\_LOGICIEL contained in an macro-order of Code\_Aster called MACRO\_MISS\_3D [U7.03.11].*

## 4.1 Orders

### *Code\_Aster for the preprocessing*

*Before using the orders of Code\_Aster specific to the coupling, it is necessary to pass by the following stages of modeling of the structure:*

- *calculation of the clean modes by order `MODE_ITER_SIMULT` [U4.52.03],*
- *definition of the dynamic interface, producing type (`CRAIGB` (recommended) or `MC-NEAL`) and its grid of the interface ground-structure, by order `DEFI_INTERF_DYNA` [U4.64.01],*
- *definition of a modal base supplements by order `DEFI_BASE_MODAL` [U4.64.02]: it calculates the static modes of the dynamic interface previously definite and complete the base of the clean modes if base is of the `TRADITIONAL` type. It is also possible of to calculate unspecified static modes directly without dynamic interface (in its case one does not use order `DEFI_INTERF_DYNA`) by order `MODE_STATIQUE` [U4.52.14] and to define a modal base then supplements of type `RITZ` by the order `DEFI_BASE_MODAL`. The interest of the modal bases of `RITZ` is to be able to assemble modes calculated with boundary conditions different. For example, modes dynamic calculated in base embedded with all ddls of the interface blocked and their static modes of interface calculated in various ways:*

- *maybe with a solid condition of connection which confers on the interface a movement of body rigid,*

- *maybe with modes of unspecified interface of pace calculated like clean modes (via order `MODE_ITER_SIMULT`) of the structure on carpet of springs of ground;*
- *assembly of the dynamic macronutrient by order `MACR_ELEM_DYNA` [U4.65.01], with to leave the modal base previously definite.*

*The data to be transferred from Code\_Aster towards PROMISS3D are obtained by the use of 2 specific orders:*

- *first order `IMPR_MACR_ELEM` [U7.04.33] makes it possible to produce the grid of the interface ground-structure and modes static and dynamic reduced to this interface. These terms are used to establish the contribution of the structure on the impedance.*
- *evolution in time or frequency whose user will provide the moments or the frequencies of restitution.*

*If the evolution is frequential, the frequencies of calculation, defined in PROMISS3D, must*

*to be coherent with that defined in IMPR\_MISS\_3D (generally one uses the beach of frequency of study between 0 and 30 Hz at the time D`studies seismic).*

*If the evolution is temporal, the beach of restitution in time defined in IMPR\_MISS\_3D must be included/understood in the duration of the seismic excitation.*

*One can, for the calculation of this evolution, to define at the same time loadings in the structure by the key word factor EXCIT, including/understanding the vector assembled correspondent with each one of*

*these loads, and of the loadings coming from the ground (signals of seismic excitation) by key word factor EXCIT\_SOL, including/understanding the type of excitation and the direction of each one of these*

*loads. In each one of these key words factors, one also gives the signal in frequency or in time associated with the definite load. Loadings given by EXCIT or EXCIT\_SOL in the same call to IMPR\_MISS\_3D are combined in only one evolution calculated by PROMISS3D. IMPR\_MISS\_3D is thus réépétable to obtain several calculated evolutions.*

*One initially encloses the data file of Code\_Aster by the FINE word then one carries out. One creates thus concepts results (modes and dynamic macronutrient in particular) on a basis of data stored on the central machine of treatment.*

*One thus gives the hand to PROMISS3D in order to calculate by a resolution in the field frequencies each evolution previously definite. According to the strategy of restitution (in time or frequency) of this evolution, one will apply or not one opposite transformation of Fourier.*

*It is possible to treat in the same tender without writing on a basis of data orders of preprocessing, the launching of PROMISS3D by MACRO\_MISS\_3D [U7.03.11] and orders of postprocessing. But except for the problems of small cut, it is strongly advised, for reasons of size memory and control of parameter time in the classes of tender, to continue to split the study into 3 time and to work with a data base Aster.*

## 4.2 Orders

### **Code\_Aster** for postprocessing

*Order LIRE\_MISS\_3D [U7.02.31] makes it possible to recover an evolution of its choice among those calculated by PROMISS3D, the choice being done by the data of a logical unit. It is necessary to point out the type of the evolution, transient or harmonic. In this last case, one recover at the same time the real part and the imaginary part data for each frequency of calculation of displacements, speeds and accelerations generalized. By the data of the modal base supplements projection, via the dynamic macronutrient, one then obtains the transitory or harmonic evolution on the physical base of the structure modelled by Code\_Aster.*

*One can then carry out the traditional postprocessing of a seismic study:*

- *Extraction of the temporal evolutions of fields of acceleration or displacement to various levels of ground or structure by order RECU\_FONCTION [U4.32.03].*
- *Calcul of the spectra of response in these same levels of ground or structure by order CALC\_FONCTION [U4.32.04] and operand SPEC\_OSCI.*

## 4.3

### **Orders specific to MISS3D**

#### 4.3.1 Orders

*It is possible, except standard use of the Code\_AsterPROMISS3D interface, to use tools of calculations specific to MISS3D and to recover the useable results or not by Code\_Aster.*

*Thus, while acting on the files of preprocessing PROMISS3D (cf [§3.3] and [Figure 4-a]) related to optimization of calculations (extension .optimis) and/or with the calculation data (extension .in), one can to profit from the following options (cf [§ 5.1.4] to have examples of use):*

- *Calcul with variable step of frequency. The resolution of the equation of the waves (cf [§ 2]) is done then in the field of the frequencies with a more or less coarse step according to bands' frequencies. That makes it possible to refine around the interesting frequencies and to be less precis elsewhere [§ 5.1.4.1].*
- *Définition of points of control. The points of control make it possible to recover information, in particular on the incidental fields and the fields diffracted by (S) interface (S) (cf [Figure 3-a]), anywhere in the ground. For that one must write a file of instructions MISS3D (his name and its extension is completely free) which will make it possible to extract towards an output file from the evolutions from fields incidental or diffracted for each point of control and in each direction of space [§ 5.1.4.2].*
- *In the case of buried foundation (cf [§ 5.1.3.2]) of fictitious resonances appear in certain configurations: soft grounds, wide foundation raft. They are due to the resonance of*

*started from ground excavated and are located at a frequency close to  $F$*

*$= V 4H$*

*fictitious*

*$P$*

*where  $V$  is*

*the speed of the wave of compression and  $H$  depth of the excavation.*

*An option makes it possible to be freed some by using order RFIC in the file related to the optimization of calculations (extension .optmis) [§ 5.1.4.3].*

*· Simultaneous Calcul of the impedances of ground and a transitory and/or harmonic answer of structure.*

*For that one must use a file of instructions MISS3D which will make it possible to write in one output file values of the impedances of ground or the seismic forces according to frequency for all ddls of the interface [§ 5.1.4.4].*

### **4.3.2 Files MISS3D**

*Two files of MISS3D, located in the repertory associated with the study on the waiter dedicated to Code\_Aster and with software PROMISS3D, are interesting to check or control which types of calculations are carried out at the time of the study and time associated with each orders MISS3D.*

#### **4.3.2.1 the data file principal**

*It has necessarily the suffix .in (nom\_étude.in for example) and contains all the orders used by MISS3D at the time of the study. It can call upon auxiliary data files. It break up schematically into three parts:*

*· definition of the data,*

- *stages of calculation,*
- *postprocessing,*

*these various phases being able to be connected and repeated by respecting the logic of the program. The execution can be carried out in several phases with resumptions of the various stages of calculation*

#### **4.3.2.2 auxiliary data files**

*The whole of the data necessary to the definition of a complex problem led to a file of order big size in which the hierarchy of information tends to disappear. Of more, often of similar calculations data files have which different only from some lines, common parts being able to be consigned in the same file. In order to allow of such cuttings, it is possible in certain menus to disconnect the reading of the data on a file auxiliary by means of key word FICP.*

#### **4.3.2.3 the output file**

*It has necessarily the suffix .out (nom\_étude.out for example) and gives an indication of the unit orders read by the program, as well as the times CPU spent in each phase of calculation. The information printed during the various phases of the program is detailed for each key word.*

***Case of application of taking into account of the ISS by the interface***

## ***Code\_Aster - PROMISS3D***

*To take into account the ISS that amounts representing the ground by a mechanical system are equivalent. Two methods are currently used:*

- lawful method within the competences of ground for which stiffnesses of the system of springs of ground independent of the frequency and are adjusted on the first mode of swinging and first mode of pumping of the system coupled ground-building (S),*
- frequential method of coupling where the impedance of the ground evolves/moves according to frequency.*

*It is the frequential method of coupling which is implemented in PROMISS3D [bib1] for to model the ISS. However, this method makes it possible to determine the stiffnesses of the system of springs of ground of the lawful method thanks to a specific option of the chaining Code\_Aster/PROMISS3D (option MISS\_IMPE of order MACRO\_MISS\_3D). In this case, it calculation follows the following diagram:*

## **5.1**

### **chaining**

**Code\_Aster - PROMISS3D: Stages and parameters**

*Calculations are carried out by implementing the Code\_Aster chaining - PROMISS3D. The different ones parameters and stages necessary to the calculation of ISS are described below:*

#### **5.1.1 Data transmitted by Code\_Aster (cf [Figure 4-a])**

**Code\_Aster transmits to PROMISS3D: the grid of the interface enters the ground and the structure (face lower of the foundation raft), the modal base combining the dynamic modes of the structure and the modes statics as well as projection on this basis of the matrices  $M$ ,  $K$  and  $C$ . This operation is carried out via operator `IMPR_MACR_ELEM` of Code\_Aster.**

**Code\_Aster transmits also the data relating to the seismic excitation : they are them accélérogrammes  $acc1$ ,  $acc2$  and  $acc3$ . That is done thanks to order `IMPR_MISS_3D` of Code\_Aster.**

**The whole of the data transmitted via operators `IMPR_MACR_ELEM` and `IMPR_MISS_3D` are printed in the file `nom_étude raster` result of the type: `libr` on unit 26 per defect.**

#### **5.1.2 Data specific to PROMISS3D for its calculation in the field frequential**

**PROMISS3D is based on the assumption of linearity as well from the geometrical point of view as of the point of**

*sight of the behavior of the materials [bib1]. This assumption of linearity makes it possible to solve them problems in the frequential field. It is in the file: nom\_étude.optmiss, which is in the repertory associated with the Aster study, which one defines the parameters necessary to calculations in field of the frequencies. One finds there in particular the beach of frequency [Fmin, Fmax] in which will be carried out the calculation and the step of sampling dF. The file nom\_étude.optmiss is given in appendix 1 of the document.*

*The rules of adjustment of the parameters are recalled in the document [bib1]. For our part us took the following parameters for the study of a nuclear small island:*

### **Fmax**

*The beach of frequency depends on the nature of the ground. The maximum frequency reserve is 20 Hz (ground means-slackness).*

$$dF = 0.1 \text{ Hz}$$

*The sampling rate retained is identical to that of accélérogrammes acc1.c2, acc2.c2 and acc3.c2 used for the seismic excitation.*

$$F_{min} = 0.1 \text{ Hz}$$

*This parameter is a function of the two precedents. It is necessary that the report/ratio*

*F*

*- F*

*Max*

*min is an entirety.*

*dF*

$$Z0 = -11.60 \text{ m}$$

*One must return the dimension of the base of the foundation. For our study the foundation is surface. Axis OZ of the model must always be vertical and the normals with plans of the grid of the foundation are obligatorily directed towards the interior of field of the ground.*

### **5.1.3 Data relating to the ground**

*It is in the file nom\_étude.sol, which is in the repertory associated with the Aster study, that one described the data relating to the ground. The constitution of the ground laminated there is indicated like*

*the site of the hearth of the seismic excitation and parameters of sampling of the functions of Green. The file nom\_étude.sol is given in Appendix 1 of the document.*

**·**

· *The modulus of rigidity G, the modulus of elasticity E (Young) and the coefficient of*

**E**

*Poisson are connected by the relation: G =*

**·**

**2 (1+ )**

### 5.1.3.2 space Discretization of the ground and Geometry of the stratification

*The discretization in voluminal finite elements of the half space infinite ground is not accessible. It is traditional for fields not limited of  $R^3$  to have recourse to a formulation by equation integral based on the knowledge of a fundamental solution which for (S) the medium (X) considered (S) in ISS is called: functions of Green. This solution is then discretized by finite elements of border what makes it possible to limit the space discretization of the field and thus to net only it (or ) the interface (S) (cf [§ 5.1.3.3]).*

#### **Recalls:**

*The functions of Green give the “impulse” response of the medium to a source specific, in the absence of any reflective surface. The solution makes it possible to reproduce the signal source with a shift corresponding to the time of way source-receiver, and a decrease of the level proportional to the distance source-receiver. Adapted, the functions of Green can take into account all or some boundary conditions on obstacles. The use of these functions is particularly useful for the integral formulations of the problems of radiation by the structures and of diffraction by obstacles.*

*The finite elements of border built and used by PROMISS3D are generated from “connector industry” of the grid of the foundation belonging to the external field (Code\_Aster). It grid must be carried out to leave D`linear or quadratic surface elements to the normals imperatively directed towards the interior of the ground. However, it is to be announced that the presence of elements quadratic on the interface nothing brings. Indeed, for PROMISS3D, the fields being used for calculation functions of Green are constant by side of element (the presence of node S intermediaries does not have no interest for PROMISS3D). Moreover, it should be noted that PROMISS3D has a method of calculation original which avoids netting the interface between the various layers of the ground. Two cases of figure can arise:*

- *The foundation is surface: In this case, it is enough to only one level source and receiver located on the free face (at the higher level of the soil horizon in contact with the air). Concretely, in the file nom\_étude.sol one specifies that only one source is necessary, thanks to the key word SOURCE, by indicating if one solves a problem in geometry 2D or 3D. The key word RECEP, which announces the position of the receiver for calculation functions of Green, must appear on the description of the 1st layer. constraints being null on the free face, it is useless to calculate them what leads to to use option ALGO\_DEPL for the calculation algorithm of the functions of Green.*

***Appear 5.1.3.2 - has: Representation of the ground with shallow foundation***

*· The **foundation is buried**: It previously was seen, the finite elements of border built and used by PROMISS3D are generated starting from the grid of the foundation belonging to the external field (Code\_Aster). In the case of a grid cutting it volume of laminated space, it is appropriate to have several levels sources and receivers to cover the whole of the grid. Thus, on the side part of the buried foundation, one place:*

*-*

*a source in the centre of gravity of each element, as on the level of the base of foundation (cf [5.1.3.2 Figure - B]),*

*- a receiver on points of Gauss of each element. The rule stated in PROMISS3D is to lay out with more the 6 receivers on each element but it is recommended to use only 4 of them placed at the top of the element like all them quarters length of the element (cf [5.1.3.2 Figure - B]).*

*Instruction manual*

*U2.06 booklet: Dynamics HT-66/04/004/A*

***Code\_Aster*** ®

*Version**6.4**Titrate:**Interaction ground-structure with the Code\_Aster-PROMISS3D interface Dates**:**09/06/04**Author (S):**G. DEVESA, V. GUYONVARH Key**:**U2.06.07-B Page**: 14/42*

*The provision of the receivers and the sources in the file **nom\_étude.sol** is generic it is appropriate thus to use for the side part of the foundation in contact with the ground a regulated grid where all the elements have even height (cf [5.1.3.2 Figure - B]).*

*Concretely, in the file **nom\_étude.sol** one specifies the number of sources necessary, thanks to key word **SOURCE**, by indicating if one solves a problem in geometry 2D or 3D. The word is applied key **RECEP** to announce the position of the receivers, necessary to the calculation of the functions of Green, on ad hoc soil horizons. At the time of the taking into account of the burial of a foundation, **PROMISS3D** implements formulations regularized to improve the precision of calculations and to limit the effort of integration. In the case of a buried foundation it is thus imperative to use option **ALGO\_REGU** for the calculation algorithm of the functions of Green.*

*One gives below an example of file **nom\_étude.sol** commented on. One supposes, for the example considered, that the foundation is buried of 20m and that one has two elements on the height of foundation (cf [5.1.3.2 Figure - B]):*

**Note:**

*If on part of the burial, there is no rigid connection between the wall of the building buried and the ground, then it is necessary to define the surface elements of this wall without connection rigid ground-building by key word GROUP\_MA\_SOL\_SOL of operator IMPR\_MACR\_ELEM. Moreover, it is necessary to direct these surface elements towards the outside of the ground medium.*

**5.1.3.3 Parameters of sampling of the functions of Green**

**The calculation of the functions of Green follows the following stages:**

- decomposition of the solution in plane or cylindrical waves elementary,**
- resolution of the problem of the elementary waves by the methods of the coefficients of reflexion transmission,**
- synthesis of the solution in Cartesian space (space field) by transform of Fourier opposite.**

**The functions of Green are thus sampled.**

**The parameter of horizontal sampling: OFFSET**

**OFFSET =  $X_{max}/NR$**

**With  $X_{max}$  length wraps with the biggest length of the foundation. For the small island the length of to erase is 110 m =>  $X_{max} = 110 Mr.$**

**With NR, a number of points of sampling. It is given starting from the average size of**

*elements of the foundation. This length to erase it nuclear small island is approximately 3 Mr. One chooses*

*12 points of sampling per element.*

*The number of samples is thus equal to:  $NR = 110/0.25 = 440$ .*

*The parameter of spectral sampling: SPEC*

*SPEC = CAR PROMISS3D manages the parameters of sampling.*

#### *5.1.4 The parameter setting of postprocessing specific to MISS3D*

*It is possible, except standard use of the Code\_AsterPROMISS3D interface, to use tools of calculations specific to MISS3D and to recover the useable results or not by Code\_Aster (cf [§4.3]).*

##### *5.1.4.1 calculation MISS3D with variable step of frequency*

*To increase the precision of a calculation of ISS, one can return a list of frequencies to the hand. It is in the file: nom\_étude.optmis (cf [§ 5.1.2]) that one defines the number and the list of frequencies on which will carry calculation.*

*Order MISS3D for the list of frequency is: LFREQ to which one must associate a continuation of values corresponding to the frequencies for which one will carry out calculation.*

*LFREQ = nf*

*with nf a number of frequencies retained for calculation*

*f1 f2 f3.... fi.... fn*

*with fi frequency for which one wishes to carry out calculation*

*One gives below an example of file nom\_étude.optmis commented on. In the example considered, the foundation surface, is excavated 11.60m and one looks at the answer on 6 precise frequencies:*

SURFING \*  
Foundation  
surface*

*Foot-note:*

*In the file nom\_étude.optmis one must choose the option either Liste of Frequency LFREQ or that is to say sampling of the Frequency: FREQ. Options LFREQ and FREQ are not compatible.*

#### *5.1.4.2 calculation MISS3D on points of control.*

*The points of control make it possible to recover information on the incidental fields, diffracted or radiated by (S) the interface (S), anywhere in the ground.*

*To carry out calculations on points of control, one indicates, in the file: nom\_étude.optmis (cf [§ 5.1.2]), their number (instruction CONT) like their geometrical co-ordinates (X, y, Z) in ground.*

*The calculation of the fields starting from the points of control is post-treaty as well in time in frequency by MISS3D because it does not intervene in the resolution of the problem coupled between the different ones*

*under-fields. One must thus define, in the nom\_étude.optmis (cf [§ 5.1.2]), a data file auxiliaries (cf [§ 4.3.2.2]) (instruction FICP) which must preferably (that is strongly to advise) to reside in the repertory associated with the study on the waiter dedicated to Code\_Aster and the software*

*One can refer to the example of postprocessing of points of control with accompanying notes page following to obtain an example of file of post treatment (fichier.post) by taking guard however to replace order CUI (incidental field) by CTOT or CSOL.*

*Foot-note:*

*By defect the instructions of the table above deliver results in displacement. To obtain the results of speed or in acceleration it is necessary to use the operand CAPTIONS followed key word QUICKLY or ACCE. For example: CUI CAPTIONS ACCE in this case MISS3D calculates the response in acceleration to the point of control.*

*Caution:*

*It is imperative to be coherent on the type of calculation to realize compared to the file .sign (cf .2) exploited for postprocessing. If this file comes, for example, of one signal in acceleration it is appropriate to seek a result in acceleration.*

5)  
*As MISS3D works in the frequential field, one must specify, among all them sampled frequencies, on which numbers of frequency one wishes to carry it out postprocessing (instruction FREQ).*

*Foot-note:*

*In the case of a postprocessing in time cf 1. , it is advisable to select all the frequencies (instructions FREQ ALL), if not a filtering will be automatically applied.*

6)  
*To specify starting from which type of fields of excitation one will carry out postprocessing (instruction FIELD). One can thus use one, two or the three fields relating to the waves of pressure and shearing in the ground of the incidental far field.*

7)  
*To indicate on which degrees of freedom one wishes post-to treat (instruction DDL).*

*Foot-note:*

*in 3D:*  
*DDL 1 corresponds to direction X*  
*DDL 2 corresponds to the direction y*  
*DDL 3 corresponds to direction Z*

8)

*To define the check-point on which one carries out postprocessing (instruction NOT).*

*One gives below an example of file nom\_étude.optmis commented on. For the example considered, the foundation surface, is not excavated and one carries out postprocessings on two points of control:*

*\* File Nom\_etude.21 (.optmis)*

*FREQ .01 35.01 .25*

*\* Calculation between 0.1 Hz and 35.01Hz by step of 0.25 Hz*

*ZO 0.*

*\* Not excavated foundation*

*SURFING*

*\* Shallow foundation*

*CONT 2*

*\* 2 points of control will be used for the post-*

*\* treatment*

*0. 100. 0.*

***5.1.4.3 calculation MISS3D in foundation buried with suppression of fictitious resonances***

*The formulation of the elements of borders applied to the dynamic problem of the interaction ground structure can reveal frequencies of fictitious resonances which correspond to frequencies of excitation of the finished field hidden (foundation) in a semi-infinite field (ground).*

*These fictitious resonances appear in certain configurations: soft grounds, large foundation raft (cf [§ 4.3.1]).*

*To free itself some one uses order RFIC in the file: nom\_étude.optmis (cf [§ 5.1.2]).*

*Calculation with the elimination of fictitious resonances can be is carried out directly during the 1st calculation*

*MISS3D is post-treaty by MISS3D after having realized of the phenomenon in comparison with results.*

*Foot-note:*

*Order RFIC is very greedy in computing times. To use can go until doubling computing times for MISS3D. It is thus advised to use order RFIC rather in postprocessing.*

*The syntax of order RFIC of MISS3D is as follows:*

*RFIC telemfd with telemfd size in meter of the smallest element of the grid of the foundation One gives below an example of file nom\_étude.optmis (cf [§ 5.1.2]) commented on. In the example considered, the foundation is buried a depth of 6.05m. Size of smallest element of the foundation is 3 Mr. One looks at the answer on 6 precise frequencies in being been free from the problem of fictitious resonances:*

#### **5.1.4.4 calculation MISS3D with simultaneous research of the impedances of ground**

*The impedances of ground express the dynamic rigidity of the field. They are expressed in the form of square matrix depending on the frequency. Each line and each column of this matrix corresponds to a particular mode, a term of the matrix being the virtual work exerted by one of these modes on another mode.*

**Foot-note:**

*During a calculation in time (TIME instruction) no impedance of ground can be calculated. MISS3D makes it possible to calculate the impedances of ground (instruction IMPDC) at the same time as response of the foundation to the seism. For this calculation of the impedances of ground, MISS3D carries them out same calculations as a postprocessing with operand MISS\_IMPE of the order MACRO\_MISS3D of Code\_Aster.*

*The result of the calculation of the impedances (matrices) is stored in a file result (instruction IMPE) who must imperatively reside in the repertory associated with the study on the waiter dedicated to Code\_Aster and with software PROMISS3D.*

*One gives below an example of file nom\_étude.optmis (cf [§ 5.1.2]) commented on. In the example considered, the foundation surface is excavated a depth of 11.60m.*

**5.1.5 Output data of PROMISS3D**

*Following calculation by PROMISS3D, Code\_Aster recovers the modal factors of participation for to obtain displacement, speed and the acceleration in any point of the structure by recombination modal. This recombination can be written in the form:*

$$U(X, T) = \sum A(T) A(X) + \sum B(T) B(X)$$

With

**B**

*with  $U(X, T)$ : field of displacement of the structure*

*With,  $b$ : dynamic and static modes*

*With,  $b$ : modal factors of participation*

*For calculations of the spectra of answer, the file result which contains the factors of participations modal names  $nom\_étude.nn.t$  (where  $nn$  corresponds to the sequence number of the coming loading of Code\_Aster is the occurrence of the call to order **IMPR\_MISS\_3D**). It is created automatically under the central machine of treatment in the repertory indicated in the order **MACRO\_MISS\_3D**.*

*For the calculation of the transfer functions one applies like loading a harmonic excitation of*

*modulate 1. That is carried out in Code\_Aster thanks to order **IMPR\_MISS\_3D**. The file in left PROMISS3D comprising the dynamic response structure complexes is named then*

***nom\_étude.nn.h** (where  $nn$  corresponds to the sequence number of the loading coming from Code\_Aster is*

*occurrence of the call to order **IMPR\_MISS\_3D**). It is created automatically under the machine of treatment in the repertory indicated in macro-order **MACRO\_MISS\_3D**.*

## ***5.4***

***Method of calculation on flexible foundation with some modes of  
foundation selected***

### ***5.4.1 Principal stages of the method***

***For the calculation of ISS, PROMISS3D needs a base made up at the same time of null clean modes  
on***

*the interface ground-structure and other nonnull modes on this interface. This base corresponds to one interface of type CRAIG\_BAMPTON. For the first modes, one generally takes the modes clean of the structure obtained by blocking displacements on the interface (bases blocked) and for the seconds, one takes static the modes known as “constrained”, successively obtained while imposing a unit displacement of each degree of freedom of each node of the interface ( foundation).*

*The principle of the method implemented here consists in replacing the constrained static modes plethoric by clean modes of foundation in small number calculated on carpet of springs of ground and selected according to an established criterion.*

*Several stages are necessary to conclude calculation:*

#### **5.4.2 Determination of the carpet of springs to be placed under the foundation.**

*The values of the stiffnesses of the springs equivalent on the laminated ground of the building are given with*

*through a calculation of the transfer transfer functions under harmonic request of module 1 at the time of the study*

*with rigid foundation (cf [§5.2]).*

*One obtains the 6 values of total stiffness within the competence of the laminated ground:  $K_x$  (N/m),  $K_y$  (N/m),  $K_z$  (N/m),*

*$K_x$  (N.m),  $K_y$  (N.m),  $K_z$  (N.m). These stiffnesses, independent of the frequency, are distributed with proportion of surfaces of the elements around the nodes of the foundation thanks to the operand RIGI\_PARASOL of order AFFE\_CARA\_ELEM [U4.42.01] of Code\_Aster.*

#### **5.4.3 The calculation of the dynamic modes of the structure**

*This calculation is carried out on basis embedded with order MODE\_ITER\_SIMULT (one applies to all nodes of the foundation the following boundary condition:  $D_x=D_y=D_z=Dr_x=Dr_y=Dr_z=0$ ).*

#### **5.4.4 The calculation of the clean modes of foundation on carpet of spring**

*During calculation, one dissociates the modes with nonnull displacements of the infrastructure (to erase)*

*modes of the superstructure (buildings...) by considering that only the foundation raft is heavy. This is*

*realized while applying, with the elements not modelling the foundation, a material of which mass voluminal is null. One avoids thus, during the construction of the modal base gathering the modes of foundation and dynamic of the structure, to consider the clean modes twice of superstructure.*

*One enriches then the modal base established with [§5.4.3], via order DEFI\_BASE\_MODALE, by first calculated modes which all are of the modes of foundation since are rejected towards the high ones*

*frequencies all modes of the superstructure.*

### 5.4.5 Selection of the modes

*While reducing considerably the number of constrained modes of foundation one can manage to find the solution in answer and frequency of resonance obtained with the preceding method putting in work the totality of the static modes (cf [§5.3]) and allowing a saving of time of substantial calculation.*

*One judges that the method of reduction is interesting, in term of saving of time, when the number clean modes of foundation on carpet of spring is with most equal to the third of the number of modes statics on flexible foundation (for this study, the method is interesting if the number of modes of foundation on carpet of spring is lower than  $1731/3$  500 modes cf [§5.3]).*

*To refine the selection of the modes, one can use the method recommended by E. Balmes [bib2] which consist in retaining only the modes of foundation whose Eigen frequency remains lower than twice the cut-off frequency used during the calculation of the dynamic modes [Figure 5.4.5-a].*

*One can carry out a parametric study on the number of modes of foundation. Method put in*

*work was evaluated [bib4] and consisted in making a continuation on a basis containing the 171 modes dynamic and 500 modes of foundation and to retain at the time of the definition of the modal base only 80, then 30 and finally 20 modes of foundation. This operation was carried out by modifying in continuation it a number of modes of foundation by operand NMAX\_MODE of order DEFI\_BASE\_MODAL, then by starting again the chain of call to the successive operators starting from this operator until postprocessing.*

*It should be noted that, on this study, when one uses the method of reduction of the modes, one finds that only forty modes of foundation are necessary to reproduce the effect induced by 1731 static modes.*

***Document: U2.07.01***

***Note of use of FOURIER modeling***

***1 Goal***

***The analysis of Fourier is intended to calculate the response of structures for axisymmetric geometry solicited by nonaxisymmetric loadings broken up into Fourier series.***

***Limitations:***

- the decomposition of the loading in Fourier series is supposed to be made by the user,***
- the Aster establishment relates to only isotropic or orthotropic materials,***
- in thermics, there does not exist total order making it possible to solve a problem on several harmonics. Calculation must be done harmonic by harmonic.***

## **2 Notations**

**All the fields considered (forces, displacements, strains, stresses, flow) are expressed in cylindrical co-ordinates with following convention on the order of the components:**

**Z**

**radial component according to R**

**axial component according to Z**

**component tangential (or circumferential) according to**

**Example: ( $u_r, u_z, U$ )**

**( $F_r, f_z, F$ )**

**R**

**$u_z$**

**U**

**$u_r$**

**The grid is localised in plan (R, Z), the symmetry of revolution being done around axis OZ. trihedron (R, Z,) is directed in the direct direction.**

**Z**

**R**

*S (has)*

*S (has)*

*S (has)*

*with F*

*=*

*,*

*,*

*L*  
*(Fr fz F*  
*L*  
*L*  
*L*  
*)*

*The loads S*  
*has*

*L*  
*F and L*  
*F are introduced harmonic by harmonic and type by type by the operator*  
*AFFE\_CHAR\_MECA. One does not specify the mode nor the type on this level.*

*Example: one supposes a loading in pressure distributed symmetrical mode 1 and pure torsion*  
*(antisymmetric mode 0).*

*One will write:*

```
ch1sym = AFFE_CHAR_MECA  
(  
Model = Mo,  
PRES_REP  
=  
_F  
(  
GROUP_MA  
=  
"grma",
```

```
CLOSE = p));  
ch0anti = AFFE_CHAR_MECA  
(  
Model = Mo,
```

*FORCE\_NODALE*

=  
*\_F*  
(  
*FZ*  
=  
*F*,

*NODE = "NI"))*);

*The boundary conditions of the Dirichlet type will be introduced into a load with share:*

*to chdir = AFFE\_CHAR\_MECA (*  
*Model = Mo,*  
*DDL\_IMPO=*  
*\_F (*  
*GROUP\_NO*  
*=*  
*"grno",*  
*DX*  
*=*  
*0.,*  
*DY*  
*=*  
*0.,*  
*DZ*  
*=*  
*0.,)*  
*)*  
*;*

*The acceptable loadings by the elements of Fourier are:*

### ***4 Resolution with Aster***

*Once the loading broken up into harmonics of Fourier, harmonics being uncoupled them from/to each other (with a number of different Fourier), it is necessary to assemble and solve as many systems linear that there are harmonics.*

*Moreover, the nonanisotropic material being supposed, for the same number of harmonic, the modes symmetrical and antisymmetric are uncoupled. One will have to thus make as many resolutions (with corresponding load) that there are couples (harmonic, mode) different.*

*The establishment in Aster is different according to whether the phenomenon is thermal or mechanical.*

#### ***4.1 Thermics***

***In thermics, there is no total order making it possible to calculate several directly harmonics. One must thus proceed harmonic by harmonic. Moreover, calculations of matrix and second elementary members can be done only with orders CALC\_MATR\_ELEM and CALC\_VECT\_ELEM (and not by order THER\_LINEAIRE).***

***The mode of Fourier is to be introduced into CALC\_MATR\_ELEM by single-ended spanner word MODE\_FOURIER.***

***type of the harmonic is not necessary, the matrices (and vectors) being independent of the type. type is only taken into account with the recombination of Fourier.***

***It is important to assemble the matrices and vectors corresponding to the various harmonics with same classification in order to be able to recombine the fields results. The operator NUME\_DDL who built classification is thus used once for the first harmonic, classification thus created being re-used for all the other harmonics. This is possible if they were differentiated loads of Dirichlet of the loadings themselves (see example [§6.1]).***

#### ***4.2 Mechanics***

***The order making it possible to treat several harmonics is MACRO\_ELAS\_MULT [U4.51.02]. In***

*this macro, the harmonics is regarded as loading cases and one thus does as much of resolutions that there are harmonics. As in thermics, it is necessary to differentiate the loads from Dirichlet, who must be identical for all the harmonics, of the loadings themselves, which can vary.*

*One obtains a structure of data RESULT containing all the fields corresponding to calculated harmonics (see example [§6.2]).*

## *5 Postprocessings*

### *5.1 Thermics*

*• The calculation of flows is done by operator CALC\_CHAM\_ELEM by specifying the number of the harmonic by single-ended spanner word MODE\_FOURIER.*

*The options of calculation of flow remain the standard options:*

*FLUX\_ELNO\_TEMP to calculate flows with the nodes by element*

*FLUX\_ELGA\_TEMP to calculate flows at the points of Gauss*

*The order of the components of the vector flow is (,*

*R,*

*Z*

*).*

• *The recombination of Fourier on the temperatures is done starting from operator COMB\_CHAM\_NO [U4.72.02]. it makes it possible to obtain the temperatures in various angular sections introduced by the user.*

*The recombination of Fourier on flows is made in COMB\_CHAM\_ELEM [U4.72.03] according to even principle.*

## **5.2 Mechanics**

• *The calculation of the strains and the stresses is done by operator CALC\_CHAM\_ELEM in specifying the number of the harmonic by single-ended spanner word MODE\_FOURIER.*

*The options of calculation remain the standard options:*

*EPSI\_ELNO\_DEPL to calculate the deformations with the nodes by element*

*SIEF\_ELGA\_DEPL to calculate the constraints at the points of Gauss*

*SIGM\_ELNO\_DEPL to calculate the constraints with the nodes by element*

*The order of the components of the tensor of the deformations (resp. constraints) is (rr, zz, rz, R, Z) (resp. rr, zz, rz, R, Z).*

• *The recombination of Fourier can be done either by fields, or starting from a structure of data RESULT.*

*- by fields: in a way similar to thermics, recombination of Fourier on displacements is done in operator COMB\_CHAM\_NO [U4.72.02], that on the deformations and forced in COMB\_CHAM\_ELEM [U4.72.03],*

*- starting from a result: operator COMB\_FOURIER [U4.83.31] allows to recombine all them harmonics of the fields appearing in the structure of data RESULT. This recombination can be done on a list of angles.*

***Note of use of the static under-structuring***

***Summary***

*This document is an introduction to the use of the static under-structuring.*

*While being based on a detailed example, whose command file is presented in appendix,*

*one will read paragraphs 1, 2, 3, 4;*

*one will refer to the description of the specific orders:*

*MACR\_ELEM\_STAT [U4.44.01]*

*DEFI\_MALLAGE [U4.12.04] and,*

*DEPL\_INTERNE [U4.65.01],*

*one will return to the detailed comments of the command file [§6].*

## *1 General information*

*The static under-structuring established in Aster is usable in linear mechanics and in nonlinear mechanics on linear parts of a model. It can be done a priori with several levels: a substructure can contain other substructures of lower level.*

*All the types of elements of the “mechanical” phenomenon are accepted thus that all them loadings supported by these elements.*

*The under-structuring is currently established within the framework of the ordinary orders [U4.4-] and [U4.5-]. It is however not established within the framework of the total orders:*

**MECA\_STATIQUE, CALC\_ELEM, CALC\_NO, POST\_ELEM,...**

***An exception exists: orders STAT\_NON\_LINE and DYNA\_NON\_LINE accept static macronutrients (see [§2]).***

***The static under-structuring consists in “condensing” statically the problem to be treated: one is eliminated certain number of unknown factors (interns). There then remain the unknown factors known as “external” in less large numbers.***

***It is a method which reduces the size of the problem. One can thus expect savings of time CPU from them and in occupation of the discs. This static condensation applies naturally to the matrix of rigidity and of mass and with the second members representing the various loadings. In this case, method of condensation can be interpreted algebraically like a resolution of the system linear by the method “of elimination”. The solution of a linear problem of statics is thus not modified by the under-structuring. On the other hand, it is possible to condense the matrix statically of mass (condensation of Guyan) but in this case the research of the clean modes of the structure condensed is deteriorated by the method of under-structuring (see for example IMBERT [bib1]). It exist other methods of under-structuring for the problems of dynamics in Aster [U4.55].***

***The theoretical principles of the static under-structuring are well explained in the book of IMBERT [bib1] and handbooks PERMAS [bib2].***

***The use of the static under-structuring into nonlinear is approached in a first chapter distinct.***

***In the continuation of this document, one will suppose known these theoretical principles and one will not be interested that with the aspects “user”. For that, one will be useful oneself much of an example: the case test SSLP100 of handbook of validation Aster. We tested, through this case test, to illustrate a great number of possibilities of the software, by complicating voluntarily the test:***

- under-structuring on several levels (2),***
- use of a macronutrient to generate by successive rotations several under structures,***
- boundary conditions and loadings on several levels,***
- mix ordinary substructures and finite elements,***

•  
“following” loading or not.

*The command file of this case test which one numbered the lines is given in appendix of it document. When one wants to refer to line N of this file, one will write {line N}.*

*2*

*Use of macronutrients in STAT\_NON\_LINE (or  
DYNA\_NON\_LINE)*

*One can make a nonlinear calculation with STAT\_NON\_LINE [U4.51.03] on a model containing of macronutrients. The interest of this type of calculation is a possible profit of performances (memory and/or CPU).*

*So that calculation with macronutrients is more economic, it is necessary that the model has the broad ones*

*linear elastic zones (possibly repetitive). It is necessary as that these elastic zones (as one will condense in macronutrients) have a border as small as possible. A favorable situation will be for example the case of an entirely elastic structure with a small zone of plasticity confined [Figure 2-a].*

*rubber band*

*fissure*

*zone of potential plasticity*

*Appear 2-a*

*One will then condense all the elastic part on the only nodes of the interface with the zone of potential plasticity.*

*The use of macronutrients in STAT\_NON\_LINE (see case tests SSLP100C and D) is conditioned by the following requirements:*

- each macronutrient must be elastic linear, its temperature should not vary with the course time,*
- it cannot y have contact with macronutrients,*
- the loadings assigned to the macronutrients “constant” (are not multiplied by “FONC\_MULT”),*
- the macronutrients should not undergo great rotations,*
- “research linear” is not possible.*

*Once calculation makes with STAT\_NON\_LINE, the post usual treatments (CALC\_ELEM, CALC\_NO, POST\_ELEM) will not have an effect that on the ordinary finite elements of the model (the macronutrients are been unaware of). If one wants to examine for example the state of stress inside a macronutrient, it is necessary to use the basic commands: CREA\_CHAMP/EXTR, DEPL\_INTERNE,... (see [§4.3] and [§4.4]).*

#### ***4 Treatment of the case test by the method of under-structuring***

**.  
the initial grid contains only the meshes (and the nodes) of polygone IJBCDA,**

**.  
one defines a macronutrient (S\_1) corresponding to polygone ABCD,**

**.  
the macronutrient (S\_1) is repeated 2 times per rotation around 0,**

**.  
one obtains then the macronutrient (S\_123) corresponding to polygone ABCEGHFD,**

**.  
the final model (on which one makes the resolution) is obtained while adding to the macronutrient (S\_123) finite elements of quadrilateral IJBA.**

### **5 General organization of calculations and definitions**

#### **5.1 Construction of the total model**

**The principle of the establishment of the static under-structuring in Aster is that of a step ascending:**

**a model having been defined, one condenses it (operator MACR\_ELEM\_STAT) on some of its nodes. One then obtains a macronutrient which, functionally resembles new much finite element “larger”. This macronutrient can then be integrated in a model of level superior (operators DEFI\_MAILLAGE and AFFE\_MODELE). This new model can then be digested in its turn and so on without limitation a priori of the number of levels.**

**Definition:**

**.  
the nodes on which a macronutrient is condensed are known as “external” (the others are “interns”),**

**.  
level: it is a notion useful for comprehension of the text of orders; any level described relations of structuring between the various models and the various macronutrients.**

*For us, it is an entirety. The operation of condensation increases the level by + 1: one model of level N gives by condensation a macronutrient of level N + 1 which will be integrated into a model of level N + 1,*

*operator MACR\_ELEM\_STAT is the only operator allowing to create a macronutrient in static under-structuring,*

*operator DEFI\_MAILLAGE is the only operator using the macronutrients in static under-structuring.*

*For our example:*

*MO\_1 {line 22} is the model moreover low level (- 2),*

*S\_1 {lines 45, 59} is the intermediate macronutrient of level (- 1),*

*MA\_123 and MO\_123 {lines 68, 87} represent the grid and the model of level intermediary (- 1),*

*S\_123 {line 104} is the macronutrient of higher level (0),*

*MAG0, MAG and MOG {lines 120, 125, 129} represent grids and a model moreover high level (0): the distinction between grids MAG0 and MAG will be explained to [§6.6] and [§6.7].*

*The structuring of the model of higher level MOG can arise graphically by one tree structure, distinction between macronutrient and substructure being explained in the paragraph according to.*

## 5.2 *macronutrient and substructure*

*One calls macronutrient the result of operator MACR\_ELEM\_STAT: it is a condensed model on its external nodes.*

*One calls substructure an occurrence of a macronutrient in a of the same model level. A substructure is a macronutrient put in position in physical space. The position of one substructure is given by the co-ordinates of the nodes of the super-mesh which is associated for him.*

*The same macronutrient can give rise to several substructures by defining several positions: in our example, the S\_1 macronutrient generates 3 substructures S\_1, S\_2 and S\_3 by suitable rotations.*

*A substructure is to some extent a new “finite element”. The macronutrient is the “type” of this element: one affects a macronutrient on a super-mesh to form a substructure.*

*One calls super-mesh, the geometrical support of a substructure. It is a named object included in a grid. A super-mesh, like an ordinary mesh, is only one ordered list of names nodes.*

*Like an ordinary finite element, a substructure has:*

- *an “elementary” matrix of rigidity (and/or of mass, damping,...),*
- *“elementary” vectors of loading,*
- *a mesh support (one will speak about super-mesh),*
- *nodes carrying of the ddl.*

## ***Note of use of the static under-structuring***

***Date:***

***29/09/05***

***Author (S):***

***J. PELLET, O. Key NICOLAS***

***:***

***U2.07.02-B Page***

***: 7/14***

***With the difference of an ordinary finite element, a substructure has several limitations:***

***.***

***the mesh support is not a simple type: TRIA3,..., HEXA20: certain postprocessings are thus not possible,***

***.***

***it does not have type\_élément, not functions of form,...***

***.***

***the only options of calculation available are RIGI\_MECA, MASS\_MECA and CHAR\_MECA,***

***.***

***the nodes can be nodes of LAGRANGE coming from the dualisation from internal conditions kinematics.***

***Identification of the substructures and the macronutrients:***

***The macronutrients are concepts named by the user.***

***Substructures (as the ordinary finite elements) are identified by the name of super-meshes which support them.***

***In our example:***

***.***

***S\_1 and S\_123 are the two macronutrients defined by the user {lines 45 and 104},***

***.***

***S\_1, S\_2, S\_3, S\_123 are the names of the super-meshes (and thus of the substructures) that the user gives during the construction of grids MA\_123 and MAG0.***

***Note:***

***There is no possible confusion (by the program) between a substructure and one of the same macronutrient name (here S\_1 and S\_123 although that does not facilitate the reading of the file orders!).***

### 5.3

#### *Redescende in the substructures*

*The ascending step, that we have just detailed, makes it possible to build the total model, or final, (mog) on which one carries out the resolution:*

.  
*CALC\_MATR\_ELEM*

.  
*CALC\_VECT\_ELEM*

.  
*ASSE\_MATRICE*  
*{lines 151-184}*

.  
...

.  
*RESO\_LDLT*

*This resolution has as a result the field of displacements of the nodes of the total model. These nodes are:*

.  
*nodes of the ordinary finite elements of the model (here quadrilateral IJBA),*  
.  
*external nodes of the substructures of the model: (here only one substructure: S\_123).*

*To find the field of displacements on the internal nodes of the substructures, it is necessary then “to go down again” the tree structure of the substructures thanks to operator DEPL\_INTERNE.*

*This operator calculates the field of displacements on all the nodes of the substructure from the data of the field of displacements on its external nodes.*

*For our example and load 1:*

.  
*UIS\_123*  
*{line 193}*  
*is displacement on the substructure*  
*S\_123*

•  
**UIS\_1**  
*{line 197}*  
*is displacement on the substructure*  
**S\_1**

•  
**UIS\_2**  
*{line 199}*  
*is displacement on the substructure*  
**S\_2**

•  
**UIS\_3**  
*{line 201}*  
*is displacement on the substructure*  
**S\_3**

*Instruction manual*

**J. PELLET, O. Key NICOLAS**

**:**

**U2.07.02-B Page**

**: 8/14**

## **5.4 Postprocessings**

*Usual postprocessings: calculation of the deformations, of the constraints,... can only be made by the ordinary finite elements which only know the concept of function of interpolation.*

*One will be able to thus calculate the constraints in a given point of the structure only with the model containing the ordinary finite element containing this point. For that, it will have been necessary to calculate the field of*

*displacements on this model:*

*Example:*

•  
*to calculate the constraints on quadrilateral IJBA the model will be used: MOG and them displacements: U1*

•  
*to calculate the constraints on polygône DCEF the model will be used: MO\_1 and them displacements: UIS\_2*

*Note:*

*Since order CALC\_CHAM\_ELEM “was strongly degreased”, it is necessary to use CALC\_ELEM but for that, one is obliged to create a SD evol\_elas by the order CREA\_RESU.*

**6**

*Some comments on the command file*

*The purpose of the few comments which follow are to illustrate the orders which intervene in static under-structuring. The comprehension of these comments supposes obviously the reading precondition of the notes of use of the orders concerned:*

•  
*Orders specific to the static under-structuring:*

-  
*MACR\_ELEM\_STAT [U4.44.01]*

-  
*DEFI\_MAILLAGE [U4.12.04]*

-  
*DEPL\_INTERNE [U4.65.01]*

•  
*Orders modified for the static under-structuring:*

-  
*AFFE\_MODELE [U4.22.01]*

-  
*CAL\_VECT\_ELEM [U4.41.02]*

•  
*Orders useful for the static under-structuring:*

-  
*ASSE\_MAILLAGE [U4.12.02]*

-  
**DEFI\_GROUP [U4.12.03]**

**6.1 Operator**

**AFFE\_MODELE {line 22}**

*Since one wants to build a macronutrient starting from polygône ABCD and that the grid my contains all the elements of IJBCDA, one cannot employ the assignment: ALL: “YES”.*

*It is necessary to affect only the group of mesh ABCD (grsd2) and not to forget to affect the elements edge AD (grma14) because of the loading of pressure.*

**6.2 Operator**

**MACR\_ELEM\_STAT {lines 45-59}**

.  
*The example illustrates the fact that one can define the macronutrient in several stages successive (use of operator MACR\_ELEM\_STAT 3 times: {lines 45, 50 and 56} with symbol of enrichment &).*

*In the first call, one defines truly the macronutrient:*

-  
*its “volume”: the model mo\_1*

-  
*its external nodes {line 48}*

- *the material field and the conditions kinematics which are applied to him {line 47}.*

*Instruction manual*

*U2.07 booklet: Methods to reduce the size of modeling*

*HT-66/05/004/A*

**Note of use of the static under-structuring**

**Date:**

**29/09/05**

**Author (S):**

**J. PELLET, O. Key NICOLAS**

**:**

## **U2.07.02-B Page**

**: 9/14**

*At the time of the 2 following calls {line 50 and 56}, one enriches the structure of data of macronutrient:*

- *calculation of the matrix of condensed rigidity {line 52}*
- *calculation of two “loading cases” {lines 53 and 58}.*

*This possibility of enriching the macronutrient makes it possible “to repair a lapse of memory” without setting out again with zero:*

- *addition of a new loading case,*
- *calculation of the mass condensed for a method of Guyan.*

*Definition of the loading case 1: CHF1 {line 53}*

*This loading case is following (SUIV = “YES”) because the pressure is a loading which acts always according to the normal at the edge.*

*The fact of having specified like load CHBL\_1, is not used for nothing here because the conditions kinematics are null  $DX = 0.0$   $DY = 0.0$  {line 29}.*

### **6.3 Operator**

**DEFI\_MAILLAGE {lines 68, 84}**

*{line 70}: one defines a substructure (and the super-mesh support) by giving him the same one which the macronutrient that one to him names. It is not prohibited.*

*{line 74}*

*All the geometrically confused nodes “are unified”:*

*the side CD of S\_1 merges with side AB of S\_2,*

*the side CD of S\_2 merges with side AB of S\_3.*

*{line 76}*

*node*

*C, which has as a name N12 in initial grid MA, will have as a name NN112*

*in grid MA\_123,*

-

*node*

*E, which is the image of C of grid MA in the S\_2 substructure will have for name NN212.*

*This node E can also be regarded as the image of the node B in substructure S\_3 it could thus have had name NN310 but the convention of sticking together of the super-meshes [U4.12.04] chooses the first denomination.*

.

*{line 77}*

*Node A (N1), which had been named NN11 with line 76, is famous in N1. It is of even for the N4 nodes, N7 and N10.*

*This renaming is necessary in the sight of the assembly of the grids which one will make {line 125} because this assembly is made by pooling of the of the same nodes name.*

.

*{line 82}*

*One defines the group of nodes GH which will serve {line 107} for the definition of the outside of S\_123 macronutrient.*

#### **6.4 Operators**

*AFFE\_MODELE and AFFE\_CHAR\_MECA {lines 86, 89}*

.

*{line 87}*

*All super-meshes MA\_123 “are activated”: one affects the S\_1 macronutrient to them.*

.

*{line 91}*

*The node NN33 which is the N3 node of the S\_3 substructure is subjected to a condition of slipping support.*

#### **6.5 Operator**

*MACR\_ELEM\_STAT {lines 104, 111}*

.

*{line 109}*

*The kinematic load CHBL\_123 which corresponds to the support slipping on GH is introduced into the S\_123 macronutrient. It is advised in the note [U4.44.01] to introduce this condition at the highest level: one could have done it at the total level bus GH belongs to outside of S\_123.*

*Instruction manual*

*U2.07 booklet: Methods to reduce the size of modeling*

*HT-66/05/004/A*

---

**Code\_Aster** ®

## **Version**

**7.4**

## **Titrate:**

**Note of use of the static under-structuring**

## **Date:**

**29/09/05**

## **Author (S):**

**J. PELLETT, O. Key NICOLAS**

**:**

**U2.07.02-B Page**

**: 10/14**

**.**

**{line 109}**

**For the S\_123 macronutrient, one gives the same name of loading case CHF1 as for S\_1 macronutrient because the convention of definition of a loading case results in adding:**

**-**

**the loadings defined by the key word CHARGES (here: chbl\_123 which is not used for nothing bus imposed displacements are null),**

**-**

**loading cases possibly present on the substructures included in model: here chf1 which is present in S\_1, S\_2, S\_3.**

## **6.6 Operator**

**DEFI\_MAILLAGE {line 120}**

**.**

**{line 123} the nodes of MAG0 will have the same name as the nodes of the macronutrients being used for its definition (S\_123).**

**The nodes of MAG0 will be thus:**

**side AB: N1, N4, N7, N10**

**side GH: NN33, NN36, NN39, NN312**

**Grid MAG0 contains only one super-mesh and not ordinary mesh.**

## **6.7 Operator**

**ASSE\_MAILLAGE {line 125}**

**The grid final (or total) contains:**

•  
*all meshes QUAD4 of initial grid MA,*

•  
*the S\_123 super-mesh of grid MAG0.*

*The super-mesh is connected to meshes QUAD4 thanks to the identity of the names of the N1 nodes, N2, N7, N10 in grids MA and MAG0.*

**6.8**  
*Calculation at the total level {lines 129-184}*

•  
*{line 130} in the total grid, which contains all the meshes of my, one only affects those of quadrilateral IJBA.*

•  
*{line 131} one affects the S\_123 substructure; the model thus contains: a substructure (S\_123) and of the ordinary finite elements (IJBA).*

•  
*{line 165} one should not forget to indicate the loading case CHF1 which was defined in line 32 and which forwards by the two macronutrients S\_1 and S\_123 via name CHF1.*

**6.9 Operator**  
*DEPL\_INTERNE*

•  
*{line 193} UIS\_123 is the field of displacements on the nodes of model MO\_123 (i.e. nodes of AB, CD, EF, GH). This field of displacements corresponds to the case of load CHF1.*

•  
*{line 199} UIS\_2 is the field of displacements on the nodes of model MO\_1 (i.e. nodes of ABCD). It should be noticed that one asked for the field of displacement on the S\_2 mesh, but there is not grid “finite elements” of this part structure.*

*This is why, the field of displacement is restored in the “local” reference mark of macronutrient S\_1 (rotation of  $-45^\circ$ ). This reference mark is the only one which allows the calculation of constraints thanks to model MO\_1.*

## **7 Bibliography**

## 1 Introduction

*The indicators of error and the adaptation of grids are useful for the user to provide calculations them more reliable possible with respect to the errors of discretization (due to the method finite elements employee).*

*The indicators of error are calculated in postprocessing of Aster, while the adaptation of grid is carried out by call to an external program, specialized in this task, LOBSTER.*

*The goal of this document is to provide possible “point entrance” a most complete bound for the user wishing to implement this kind of techniques in its calculations. The plan of the document is then the following:*

- 1) the perimeter of use (which can one make?) ;*
- 2) references useful to read before use (where to go to seek information more deepened that those brought in this document?) ;*
- 3) a diagrammatic recall of the methodology of adaptation of grids;*
- 4) a recall of the orders and options to be used (how to write the command file?) ;*
- 5) a whole of councils on the “good practices” to implement (which are them points worthy of attention during the use?) ;*
- 6) some examples illustrating use of these techniques and councils the given previously (how to make in practice?).*

## 2 Perimeter of use

*The field of application of the indicators of error and the adaptation of grid is delimited by following constraints (one will refer to the reference documents given below for more details):*

- the errors taken into account are the errors of space discretization (thus the size of elements employed); in particular, errors of discretization temporal (or pseudo temporal in the case of non-linear materials) are apart from this perimeter;*
- the physical phenomena are limited to mechanics (linear or non-linear, Cf below) and with thermics (idem.);*
- in mechanics as in thermics, the behavior can be linear or not linear (except for the estimator of error of Zhu-Zienkiewicz in mechanics which treats only the behavior linear), knowing that the theoretical results of the indicators of error are obtained in linear field (their use in the non-linear field is thus not based on theoretical results but on an empirical observation of their interest);*
- the elements used can be unspecified for the use of the indicators of errors (except for the estimator of error of Zhu-Zienkiewicz in mechanics, which treats only the elements 2D; estimator ZZ2 does not accept that grids made up either of triangles or of*

*quadrangles); on the other hand, the use of the adaptation of grids with LOBSTER requires for the moment use of elements in the list (not, segment, triangle, tetrahedron) with exclusion of very other. These elements can be linear or quadratic.*

## 4

*Recall of the orders and options Aster to be used*

## 4.1

*Estimator of error in mechanics of Zhu-Zienkiewicz*

*The calculation of the estimator of error is carried out directly in operator CALC\_ELEM with options:*

*OPTION= `ERRE\_ELEM\_NOZ1' for estimator ZZ1;*

*OPTION= `ERRE\_ELEM\_NOZ2' for estimator ZZ2.*

*The calculation of the field (with the nodes) of smoothed constraints can separately be started (not very useful in practical):*

*OPTION= `SIGM\_NOZ1\_ELGA' for smoothing ZZ1*

*OPTION= `SIGM\_NOZ2\_ELGA' for smoothing ZZ2*

*The estimator provides:*

*· a field by element comprising 3 components:*

*“ERREST”*: the absolute error estimated on the element (K);

*K*

*“NUEST”*: the relative error estimated on the element rel (K)

*( )*

*= 100×*

*;*

*(K) 2*

*2*

*+ H 0, K*

*“SIGCAL”*: the standard of energy of the calculated solution H

*;*

*0, K*

*· of the exit-listing comprising same information at the total level.*

## 4.2

*Estimator of error in mechanics of the residue type*

*For calculating the indicator of error, it is necessary to carry out the calculation of the field (with the nodes by elements) of*

*constraints to normalize the error, by operator CALC\_ELEM:*

*OPTION= `SIGM\_ELNO\_DEPL' in elasticity (after MECA\_STATIQUE);*

*OPTION= `SIEF\_ELNO\_ELGA' into non-linear (after STAT\_NON\_LINE).*

*The calculation of the estimator of error itself is also carried out in operator CALC\_ELEM with the options:*

*OPTION= `ERRE\_ELGA\_NORE' for calculation at the points of Gauss;*

*OPTION= `ERRE\_ELNO\_ELGA' for calculation with the nodes by elements.*

**The estimator provides:**

· **a field by element comprising 3 components:**

**“ERREST”**: the absolute error estimated on the element (K);

**K**

**“NUEST”**: the relative error estimated on the element rel (K)

( )

= 100×

;

(K) 2

2

+ H 0, K

**“SIGCAL”**: the standard of energy of the calculated solution H

.

0, K

***For correct use, it is necessary to pay attention to the following points (cf R7.10.03 documentation):***

- preliminary call “FLUX\_ELNO\_TEMP” obligatory before the calculation of the indicators of errors;***
- homogeneity enters the parameter setting of the thermal solver and the tool for postprocessing;***
- particular rules of overload concerning the loadings (generation of alarm <A> in case of non-observance);***
- calculation on all the grid associated with the model (generation of <F> error in the event of non-observance) between two steps of time contiguous or not (generation of alarm <A> in the event of non-observance);***
- all the elements 2D-plan/axi and 3D are treated (except PYRAM: generation of alarm <A>);***

- *all the limiting conditions except ECHANGE\_PAROI, FLUX\_NL and RAYO are taken into account (generation of alarm <A> in the event of use of ECHANGE\_PAROI, FLUX\_NL or RAYO);*
- *the grid tolerates the “outlines” but requires “to be cleaned a little” (not of SEG/FACE intercalated in surfaces/volumes, problem of symmetrization, points double: generation of alarm <A> or <F> error).*

**NIVE\_MAX**

*Max. level of refinement*

**NIVE\_MIN**

*Level min. of refinement*

*(\*) example given on a non-linear calculation, use of the indicator in absolute residue.*

*Other possible options:*

- *update of fields on new grid (MAJ\_CHAMP); one cannot (still) put up to date of the fields at the points of Gauss (like the variables intern for example);*
- *diagnoses on the quality of the grid (QUALITY, INTERPENETRATION, SIZE, CONNEXITY).*

*Precautions for use:*

- *adaptation of a total grid (not of selection by meshes, groups of meshes, nodes, group nodes);*
- *the groups of meshes are adapted, on the other hand the groups of nodes are left unchanged (it is thus necessary to be compelled to impose boundary conditions on groups of meshes and not of the groups of nodes); it is thus necessary to proscribe (but it is a rule of good feel) the direct use of meshes and nodes at the time them assignments to prefer the concept to him of group meshes;*
- *the recoveries (by the key word “CONTINUATION”) are to be avoided: LOBSTER loses the hierarchy then refined elements: the first grid of the continuation is considered by LOBSTER an initial grid (without possibility of déraffiner for example);*
- *one recalls that the adaptation by LOBSTER accepts only nodes, NOT, SEG, SORTED or TETRA, of degree 1 or 2, in a grid conforms in related zones or not, in the same way dimension or not;*
- *LOBSTER does not carry out yet the follow-up of curve (it is based on the provided elements: by example, if the grid of a circle is provided in the initial grid by its approximation in NR segments of order 1, LOBSTER will refine possibly the NR segments but the circle will be always considering geometrically like a succession of these NR segments).*

## **4.5 Lookahead**

*of one  
grid*

*The diagnosis on the quality of a grid activable in the macro **MACR\_ADAP\_MAIL** can also be obtained independently by the macro **MACR\_INFO\_MAIL**. It makes it possible to carry out the checks*

*following:*

- to check the agreement of the grid with the initial geometry (in mass, dimension, in surface and in volume);*
- to list the **GROUP\_MA** and **GROUP\_NO**, for a good modeling of the boundary conditions;*
- to diagnose possible problems (symmetrization or connexity, elements of outline, bad taking into account of boundary conditions, interpenetration of elements);*

**H**

- to evaluate the quality of the grid by the indicator*

**K**

**K =**

*(standardized to 1 for*

**K**

*equilateral triangles/tetrahedrons; by superior definition to 1). An empirical criterion can be proposed: for example, at least 50% of EFs < 1.5, at least 90% of EFs < 2, not elements with the top of 10.*

5

*The Councils and good practice*

- Choix of the indicator of error in mechanics: the user has the choice between **ZZ1** (first version*

indicator of Zhu-Zienkiewicz), ZZ2 (second version of the indicator of Zhu-Zienkiewicz), and the indicator in residues. The two first have an applicability enough reduces (2D linear for ZZ1 and ZZ2, only one standard of finite element in all the grid for ZZ2): for a “standard” use, one will prefer the indicator in residues.

- The sequence “thermomechanical operators/“UNIFORM” MACR\_ADAP\_MAIL option” (i.e without indicator of error) allows to make converge properly, automatically and easily a grid. It is however necessary to take guard with the number of degrees of freedom generated! This constitutes a solution of facility, rapid and robust, but quickly extremely expensive (rather to reserve to evaluate if there are large errors of discretization or for small studies).

- The sequence “thermomechanical operators/“FREE” MACR\_ADAP\_MAIL option” (i.e with indicator of error) allows to make converge in the most optimal possible way (taking into account the tools available) grid. This method requires more efforts than the preceding one but the number of generated degrees of freedom is proportionally much weaker.

- The sequence “operators thermomechanical/MACR\_ADAP\_MAIL” can be carried out effectively in a loop Python (of type “for buckles”), with possibly a test of exit (of type “while buckles”).

- The quality of the elements is impacted little by the process of refinement/déraffinement. Taking into account the choices operated in HOMARD®, it can even improve in 3D!

- MACR\_ADAP\_MAIL does not have process of regularization, therefore a bad grid initial a bad adapted grid will probably produce!

- The linear elements are disadvised in mechanics. The good practice is rather: P1 lumpé in thermics (PLAN\_DIAG, AXIS\_DIAG, 3D\_DIAG) and P2 (possibly under-integrated) in mechanics, cf [bib9].

- The choice of the type of finite elements premium on the quality of the meshes on which come to rest the elements (cf example of the beam below).

- The type of indicator and its mode of standardization can affect the grid

**K**  
adapted. For example, in mechanics,  $rel(K)$

( )  
= 100×

. This way of

(K) 2

2

+ H 0, K

to standardize can be dangerous: if there are zones where the standard of constraints is weak, the error will border 100% on this zone; if there are zones where the standard of constraints is very high (singularities for example), the error will be weak on this zone. It is not obviously not the required result. It is thus necessary to use the absolute indicator preferably, with less knowledge precisely than one makes.

- *In thermics, one can also “juggle” with the components of the thermal indicator and of boundary conditions, “fictitious” or not, to direct the construction of a refined grid or déraffiné by zones.*
  - *In the event of presence of singularities, it is advised to select the number of elements on which refinement carries by a fraction of elements to refine “CRIT\_RAFF\_PE” (and not by the quantum of elements presenting a superior error at a fraction of the total error “CRIT\_RAFF\_REL”). Indeed, in the case of a singularity, by using “CRIT\_RAFF\_REL”, with boils of one or two iterations of adaptation, only the elements touching the singularity will be refined. By using “CRIT\_RAFF\_PE”, other zones will be able to continue to be refined. Finally criterion “CRIT\_RAFF\_ABS” (choice by fixed barrier of error) is to be held for the cases where the user knows the problem considered very well.*
  - *As a “simple postprocessing” of the thermomechanical problem, the indicator cannot unfortunately not to provide a more reliable diagnosis in the zones where the resolution of initial problem stumbles. It is thus preferable to begin a process of adjustment, with one grid refined already a little “with the hand”.*
  - *Into thermomechanical, various strategies of adaptation of grid are offered to the user:*
    - *to only adapt the grid according to a thermal criterion,*
    - *to only adapt the grid according to a mechanical criterion,*
    - *to adapt jointly or separately (i.e with one or two loops of adaptation); in clearly to chain or couple the first two strategies.*
- Good practice during such a thermomechanical calculation led to use two grids and with to interpolate the thermal field P1 on the mechanical grid P2 (via operator PROJ\_CHAMP). If one wishes to work only with one grid, one can decline one of the strategies via option MAJ\_CHAMP of MACR\_ADAP\_MAIL. That allows, while adapting the following grid a criterion, to update the complementary field on the new adapted grid.*

*· In thermics, to carry out an adaptation of grid based on the indicator ERTH\_ELNO\_ELEM during a transient, one should not forget to start the calculation of the step time following with the old EVOL\_THER updated on the new grid.*

## **6 Examples of use**

### **6.1 Mechanical example (beam 2D)**

*It is about a metal beam (steel 16MND5,  $E = 210.103$  Mpa,  $\nu = 0.2$ ) in inflection. Calculation rubber band (MECA\_STATIQUE or STAT\_NON\_LINE) in modeling forced plane (C\_PLAN). Initial grids in TRIA3 or TRIA6.*

*6.1.3 Use*

*of*

*FREE MACR\_ADAP\_MAIL option*

*The first question to regulate during the use of free refinement with LOBSTER is the choice of the indicator of error and its component. Here, according to the principles stated in the paragraph of councils, the choice was made use the indicator in residue (even if in this case, one is in perimeter of use of the indicators of Zhu-Zienkiewicz). On the other hand, this example compares them*

*components absolute and standardized indicator in order to illustrate the prudence which the use imposes of the standardized component.*

*The grid is here linear in order to clearly illustrate the effect of the adaptation of grid, because one*

*saw*

*previously that the initial grid gives already results of good quality with elements of order 2.*

*Free refinement on the absolute component (for the relative component, it is enough to change in extract below `NOM_CMP_INDICA='ERREST'` in `NOM_CMP_INDICA='NUEST'`) is activated by following orders:*

**# SUBTLETY MACRO\_COMMANDE WITH RESPECT TO THE ENTRIES**

**MA [num\_calc1]=CO (“MA\_%d’ % (num\_calc1))**

**# REFINEMENT FREE VIA LOBSTER**

**# GRID STARTING: MA [num\_calc]**

**# GRID Of ARRIVES: MA [num\_calc1]**

**TAILLE='OUI',**

**CONNEXITE='OUI')**

*If one compares the results on the arrow with “absolute” component and the “relative” component according to the number of nodes (cf [Figure 6.1.3-a] where one added the same evolution for refinement uniform), one observes:*

- free refinement with the component absolute converges more quickly towards the reference that uniform refinement (from where interest of to make free refinement);*
- free refinement with the component relative converges more slowly towards reference that uniform refinement, which is at first sight surprising.*

*Appear 6.1.3-a: Evolution of energy in*

***function of the number of nodes***

***This last point is explained if one traces the three fields from the indicator of error, which is made on [Figure 6.1.3-b] - [Figure 6.1.3-d].***

*Initially, one is interested in thermics only to underline the possibility of using decomposition of the various terms of error. Indeed, within the framework of a “standard” use (i.e. when all the terms of error interest the user), will have to be chosen the total error (“ERTABS” or “ERTREL”); on the other hand, if the user is particularly interested by good taking into account of the boundary conditions, it can thus direct refinement by using the different ones*

*terms (of flow or exchange in this case). For example, on the basis of the grid [Figure 6.2-a] - one will note that this grid checks one of our councils which is to start from a “reasonable” grid - one carry out a refinement on the relative total error, cf the result [Figure 6.2-b]:*

**# GRID STARTING: CHECHMATE [num\_calc]**

**# GRID Of ARRIVES: CHECHMATE [num\_calc1]**

**MACR\_ADAP\_MAIL (**

### ***Appear 6.2-c: Grid refined starting from the relative error on the term of exchange***

*One is interested now in coupled thermoelastic calculation. This problem remains rather simple since it one step of time has there. According to the councils given previously, one carries out this calculation coupled on two different grids: a “thermal” grid linear on which will be based lumpés elements and a “mechanical” grid quadratic, the passage of the one with the other being carried out by operator “PROJ\_CHAMP”.*

*More precisely: with each stage of the loop of refinement, one starts by calculating temperature on the thermal grid:*

```
TEMP [num_calc] =THER_LINEAIRE (  
MODELE=MOT [num_calc],  
CHAM_MATER=CHMATT [num_calc],  
EXCIT= (  
_F (LOAD = CHT [num_calc]),  
_F (LOAD = CLIMT [num_calc],),)  
)
```

*then one projects this temperature on the mechanical grid (one created a model beforehand thermics MOT2 related to the mechanical grid):*

```
TEMP2 [num_calc] =PROJ_CHAMP (  
METHODE='ELEM',  
RESULTAT=TEMP [num_calc],  
MODELE_1=MOT [num_calc],  
MODELE_2=MOT2 [num_calc],  
TOUT_ORDRE='OUI')
```

*One uses this temperature under the boundary conditions of mechanical calculation:*

```
CLIMM [num_calc] =AFFE_CHAR_MECA (  
MODELE=MOM [num_calc],  
TEMP_CALCULEE=TEMP2 [num_calc],  
DDL_IMPO= (_F (GROUP_NO=' GM39', DX=0.0, DY=0.0),  
_F (GROUP_NO=' GM40', DX=0.0, DY=0.0),),)
```

**P. BADEL, O. BOITEAU, V. CANO** Key

:

*U2.08.01-A Page*

*: 19/30*

*mechanical calculation is carried out:*

```
DEPLA [num_calc] =STAT_NON_LINE (MODELE=MOM [num_calc],  
CHAM_MATER=CHMATM [num_calc],  
EXCIT= (_F (CHARGE=CLIMM [num_calc],),  
_F (CHARGE=CHM [num_calc],  
FONC_MULT=F_INST,)),  
COMP_INCR= (_F (RELATION=' ELAS',  
TOUT=' OUI',)),  
INCREMENT=_F (LIST_INST=L_INST),)
```

*One calculates the indicators of thermal and mechanical error:*

```
TEMP [num_calc] =CALC_ELEM (reuse=TEMP [num_calc],  
RESULTAT=TEMP [num_calc],  
MODELE=MOT [num_calc],  
TOUT=' OUI',  
TOUT_ORDRE=' OUI',  
CHAM_MATER=CHMATT [num_calc],
```

```
EXCIT= (  
_F (LOAD = CHT [num_calc]),  
_F (LOAD = CLIMT [num_calc],),),  
OPTION= (  
“FLUX_ELNO_TEMP”,  
“ERTH_ELEM_TEMP”,  
“ERTH_ELNO_ELEM”,),)
```

```
DEPLA [num_calc] = CALC_ELEM (reuse=DEPLA [num_calc],  
RESULTAT=DEPLA [num_calc],  
MODELE=MOM [num_calc],  
TOUT=' OUI',  
CHAM_MATER=CHMATM [num_calc],  
EXCIT= (_F (CHARGE=CLIMM [num_calc]),  
_F (CHARGE=CHM [num_calc],),),  
TOUT_ORDRE=' OUI',  
OPTION= (  
“SIEF_ELNO_ELGA”,  
“ERRE_ELGA_NORE”,),)
```

*then one connects with the adaptation of the thermal and mechanical grids*

```
MACR_ADAP_MAIL (  
ADAPTATION=_F (

*Before starting again at the following stage...*

### ***6.3 Example***

#### ***thermoplastic***

*One considers the structure of following revolution (modelled into axisymmetric):*

where the grayed parts are plastic, the elastic remainder. The loading is applied in 2 stages:

- the first consists of a purely mechanical loading (pressure on the zone with arrows on the diagram), with a phase of load followed by a phase of discharge;
- the second consists of a transitory thermal loading (condition of exchange on lower parts and higher of the structure).

### **6.3.1 Strategy of mending of meshes and list of moments**

**The loading is discretized according to a list of moments, it raises the question then: which strategy to adopt with respect to mending of meshes? Indeed, according to the treated case, one can:**

- **to re-mesh with each step of calculation: the grid is then adapted to each step of calculation individually. It is then necessary to project the fields of a grid on the other (what is not still completely possible in non-linear mechanics);**
- **to re-mesh only once, at the end it calculation, and to start again calculation since the beginning with new grid.**

**The first strategy is to be adopted if the zones of refinement evolve/move much, us in will see an example in following thermal calculation; the second can be adopted if the zones of refinement evolve/move little, as in this mechanical case where it is a question of following growth of a plastic zone.**

### 6.3.2 Calculation mechanics

*For mechanical calculation, one thus adopts the following strategy:*

- 1) calculation of all the list of moments;
- 2) mending of meshes
- ;
- 3) repetition of (1 & 2) until the satisfactory result.

*It is not so much the implementation in Aster which is interesting in this case (which differs from the settings*

*in work the preceding ones only by the fact that several moments ago of calculation) that the results obtained by adaptation of grid on a non-linear case. For recall, calls for calculation indicators of error and for mending of meshes are as follows:*

*V1 [num\_calc] =CALC\_ELEM (reuse =V1 [num\_calc],*

*MODELE=MO1 [num\_calc],*

*CHAM\_MATER=CM1 [num\_calc],*

*INST=-1.0,*

*OPTION= (“ERRE\_ELGA\_NORE”),*

*RESULTAT=V1 [num\_calc],)*

*MA [num\_calc+1] =CO (“MA\_%d' % (num\_calc+1))*

*MACR\_ADAP\_MAIL (*

*ADAPTATION=\_F (*

*FREE = “REFINEMENT”,*

*MAILLAGE\_N = MA [num\_calc],*

*MAILLAGE\_NP1 = MA [num\_calc+1],*

*RESULTAT\_N = V1 [num\_calc],*

*INDICATOR = “ERRE\_ELGA\_NORE”,*

*NOM\_CMP\_INDICA=' ERREST',*

*NUME\_ORDRE = 4,*

*CRIT\_RAFF\_PE = 0.1,*

*NIVE\_MAX = 5),*

*QUALITE=' OUI',*

*INTERPENETRATION=' NON',*

*TAILLE=' OUI',*

*CONNEXITE=' OUI'*

)

*To judge contribution of mending of meshes, let us look at the radial constraints on the segment indicated on*

*[Figure 6.3.2-a], which is compared with a “reference” obtained by 3 uniform mendings of meshes: profit*

*the mendings of meshes based on the indicator of error is visible.*

*If one looks at the results at the last moment calculated, in particular the temperature on the line of post-*

*treatment already used in mechanics, cf [Figure 6.3.3-c], one notes the interest of the adaptation of grid. As one will be able to note it on the grids initial and adapted (with the last step of time), Cf [Figure 6.3.3-a] [Figure 6.3.3-b], the grid did not change in the vicinity close to this line of examination: the improvement of the calculated temperature comes from the zones that one refined by elsewhere. It will be also noticed that the refined grid is not very intuitive: it is there too about one of interest of the automatic adaptation of grid.*

**1 Introduction**

*Whatever the type of problem considered, thermal, mechanical, etc, Code\_Aster produces two types of results: buildings or total. It can be a field distributed on the grid, like temperature or constraints, or it can be a total value, like the rate of refund of energy. But in both cases, we represent ourselves this result like a function of data. These data are of varied origin. We find as follows:*

- *geometry of the field of calculation,*

- *mode of discretization through the choice of the grid,*
- *boundary conditions, like the imposed temperatures or displacements,*
- *loadings, like the sources of energy or the imposed pressures,*
- *material properties,*
- *choices of calculation, like the criteria of convergence.*

*The list is not exhaustive. Obviously, the result is sensitive to each one of these data. But obviously we do not propose automatic calculation of all the sensitivities. It is even of many cases where a quantified evaluation does not have a direction. Such as for example quantifying the sensitivity to*

*choice of the method of resolution of the matrix system related to calculation? Calculations of sensitivity available with Code\_Aster are restricted with the cases where the data is a real parameter, clearly identified in the data file, and where we know to derive the function which binds this data to the result.*

*Let us take some examples:*

- *choice of the grid: not, because it is not a real parameter,*
- *value of displacement or imposed pressure: yes,*
- *a number of steps of time: not, because it is an entirety,*
- *property of materials: yes and not; yes if the significant value is a pure Young modulus, not if one is interested in a property given by a curve point by point,*
- *criterion of convergence: not, because we do not know to derive the result,*
- *etc*

*We will detail the possibilities for each type of problem. It is enough to keep present at the spirit regulate stated higher: Code\_Aster treats only the cases where the result is in the form  $U(p)$ , where  $U$*

*$p$  is a visible real parameter and where the partial derivative exist. Then Code\_Aster will produce this*

*$p$*

*derivative partial, of comparable nature total or local that the result, this derivative being calculated with not nominal of operation.*

*The physical direction attached to the value of this derivative is far from being manifest. That to say of a derivative*

*of constraint compared to a value of imposed pressure which would be worth 1,983? Without same speech of*

*units... How to interpret these results? As we have just seen it, Code\_Aster calculates one partial derivative. The use of the derivatives is double in our opinion: a help with the comprehension of studied phenomenon or an insertion in a more total process.*

*Initially, the knowledge of derived from a result compared to parameters enriches the analysis by the phenomenon. That makes it possible for example to locate the zones where the influence of one change is largest. In the same way, one will be able to compare the respective influence of two data similar. If one must make a parametric study, one will be able to choose to do it only on the most significant parameters. Attention nevertheless to compare derivative homogeneous: sensitivities to an external pressure and a pressure interns for example.*

*Into the second time, one will be able to inject the values of the derivative obtained in a process iterative. It is the case of the algorithms of optimization, of retiming, which converge while being based on value of the function and its derivative. It is also the case of calculations of mechanics reliability engineer using method FORM.*

***An example emblematic***

*We will illustrate the possibilities offered by Code\_Aster by examining an academic example in mechanics. This example will be followed until the development of its command set.*

*We consider a formed part of three materials. This part is embedded on its edge left. Two pressures are applied to the higher faces. We are interested in constraints in third material. More particularly, we would like to know the sensitivities*

*of these constraints to the various Young moduli and the imposed pressures.*

*Pressure A*  
*P Pressure B*  
*P*

*E and*  
*E and*

*Material 1: 1*

*1*  
*Material 2: 2*

*2*

*Material 3: E3 and*  
*3*

*Like let us know we it, the stress field is a function of the data:*

*= ( , , , ,*

*With*

*B*

*I*

*I*

*)*

*...*

*method,*

*grid,*

*geometry,*

*.*

*In accordance with the rules stated higher, Code\_Aster will be able to calculate each one of the*

*derivative*

*partial*

,  
,  
,  
,  
,

*To 1*

2  
3

*The result is a field expressed at the points of Gauss of each element; it is a tensor of*

*components,*

,  
*xx yy etc In the same way, the result  
will be a field expressed with*

*points of Gauss of each element. Each one of its components will be the derivative partial of*

*xx  
yy  
corresponding component of:*

,  
*, etc We will obtain them thus automatically*

*With*

*derivative partial of all the components of the tensor of the constraints compared to each one of  
parameters mentioned.*

*Before going further in the description of the calculation of sensitivity, we will specify the data  
numerical of the problem, expressed in international system.*

***How to set up a calculation of sensitivity***

***3.1 Essence***

***A calculation of sensitivity is done thanks to the introduction of the concept of “significant parameter”. Otherwise***

***known as, if one wants to derive compared to the Young modulus from the one from materials from the field, one will define one***

**“significant parameter” which will represent this Young modulus. This parameter will be seen under two aspects:**

- like a constant equalizes with the face value of the Young modulus,
- as a concept by report/ratio to which one can derive.

For each desired derivation, one will carry out the following operations:

- to define the significant parameter with its value by the order: `DEFI_PARA_SENSI`,
- to use this significant parameter everywhere where its value intervenes in the orders (loadings, materials,...),
- to ask the operator of resolution to derive the result, with the key word: `SENSIBILITE= (...)`.

## 3.2

### **To define the significant parameters**

To define a significant parameter meets this double aim: to introduce into calculation a concept which is equal to the face value of the data and which is recognized like “sensitive”. For that, one uses order `DEFI_PARA_SENSI` [U4.31.06]. Its syntax is similar to that well-known of `DEFI_CONSTANTE`:

`PA = DEFI_PARA_SENSI (VALE = 1000.)`

One must thus thus define all the significant parameters of simulation.

We draw the attention to this

: the definition of a significant parameter does not engage automatically the calculation of the derivative. Calculation will be made only for the indicated parameters

later on. One can thus define much a priori and, for a given simulation, not derive of it that compared to some, even none. The thus definite data in excess will be used like simple constants.

In our example, we will define has minimum the five parameters for which we want to obtain derivatives:

`PA=DEFI_PARA_SENSI (VALE=1000.)`

`PB=DEFI_PARA_SENSI (VALE=8000.)`

`E1=DEFI_PARA_SENSI (VALE=430000.)`

`E2=DEFI_PARA_SENSI (VALE=380000.0)`

`E3=DEFI_PARA_SENSI (VALE=130000.0)`

In accordance with the preceding remark, nothing prohibits to us to define other parameters sensitive, even if we do not intend to be useful to us about it a priori.

*NU3=DEFI\_PARA\_SENSI (VALE=0.27)*

*Instruction manual*

*U2.08 booklet: Advanced functions and control of calculations*

U2.08.02-A Page

: 7/14

### 3.3

#### **To use the significant parameters**

*The data associated with a significant parameter intervenes in general in a loading or in definition of a material. Each one of these orders will be activated by providing the parameter sensitive like entry. This entry will be seen by the order like a constant function being worth the value declared in the definition of the parameter.*

*In our example, the loadings in pressure will be declared as follows:*

```
pressure =  
AFFE_CHAR_MECA_F (MODELE=model  
PRES_REP= (_F (GROUP_MA=' BORD_H_1',  
PRES=PA),  
_F (GROUP_MA=' BORD_H_2',  
PRES=PB)  
)  
  
)
```

*The definition of three materials does without the same manner:*

```
mater_1 = DEFI_MATERIAU (ELAS_FO=_F (E=E1, NU=NU1))  
mater_2 = DEFI_MATERIAU (ELAS_FO=_F (E=E2, NU=NU2))  
mater_3 = DEFI_MATERIAU (ELAS_FO=_F (E=E3, NU=NU3))
```

*One will note that to use a concept of the type “parameter significant” instead of a numerical value*

*imply to use the definitions by functions of the loadings or materials. However, that remains similar to the cases where the values are defined by concepts of the type “constant”, technique well known users of Code\_Aster.*

### **3.4**

#### ***To launch the derivation of the principal field***

*Once the significant parameters were defined and used, it only remains to launch derivation. That is done while inserting the key word SENSITIVITY in the operator of calculation. This key word is followed list parameters by report/ratio to which one wishes to derive [U4.50.02]. In our example, us let us have:*

```
resultat=MECA_STATIQUE (
MODELE=modele,
CHAM_MATER=ch_mater,
EXCIT= (_F (CHARGE=encastre
```

```
),
_F (CHARGE=pression)),
```

```
SENSIBILITE= (E1, E2, E3, Pa, PB))
```

*This order will calculate simultaneously the field of displacements and the five field of the derivative this same displacement compared to each definite significant parameter. All these fields are expressed on the nodes of the grid.*

*For each type of problem, we will obtain the derivation of the principal field thus: temperature in thermics, displacement in static mechanics, etc*

### **3.5**

#### ***To derive the secondary fields***

*Principal field, are deduced from the secondary fields: heat flow, deformations, forced, etc These operations are activated by orders CALC\_ELEM and CALC\_NO. Thus the tensor of constraints is created by:*

```
resultat=CALC_ELEM (reuse =resultat,  
RESULTAT=resultat,  
MODELE=modele,  
CHAM_MATER=ch_mater,  
EXCIT= (_F  
(CHARGE=encastre),
```

```
_F (CHARGE=pression),  
OPTION=  
("SIEF_ELGA_DEPL",  
"SIEF_ELNO_ELGA")  
)
```

*Instruction manual*

*U2.08 booklet: Advanced functions and control of calculations*

*HI-23/03/002/A*

---

**Code\_Aster** ®

*Version*

*6.4*

*Titrate:*

*Note of use of calculations of sensitivity*

*Date*

*:*

*13/05/03*

*Author (S):*

**G. Key NICOLAS**

*:*

*U2.08.02-A Page*

*: 8/14*

*To obtain the derivative of the constraints, it is enough to insert the key word SENSITIVITY followed by*

*the list of  
significant parameters concerned.*

*resultat=*CALC\_ELEM (*reuse =resultat*,  
*RESULTAT=resultat*,  
*SENSIBILITE= (E1*,  
*E2*,  
*E3*,  
*Pa*,  
*PB)*,  
*MODELE=modele*,  
*CHAM\_MATER=ch\_mater*,  
*EXCIT= (\_F*  
*(CHARGE=encastre)*,

*\_F (CHARGE=pression)*,  
*OPTION=*  
*(“SIEF\_ELGA\_DEPL”*,  
*“SIEF\_ELNO\_ELGA”*  
*)*

*resultat=*CALC\_NO (*reuse=resultat*,  
*RESULTAT=resultat*,  
*SENSIBILITE= (E1*,  
*E2*,  
*E3)*,  
*OPTION=' SIGM\_NOEU\_DEPL'*)

**Note:**

- *When the key word SENSITIVITY is inserted in an order CALC\_ELEM or CALC\_NO, only the derived field are calculated.*
- *To calculate the derivative of a field to the elements, it is necessary as a preliminary to have calculated it standard field. On the other hand, that is useless for a field with the nodes because the operator CALC\_NO is satisfied to make an average with the nodes of a field to the elements.*

**3.6**

***Post-to treat the results***

*To print the fields of derivatives, it is enough to insert the key word SENSITIVITY in the order IMPR\_RESU. Here still, that will start only the impression of the derived fields compared to parameters concerned:*

```
IMPR_RESU (RESU=_F (FORMAT='MED',
RESULTAT=resultat)
)
```

```
IMPR_RESU (RESU=_F (FORMAT='MED',
RESULTAT=resultat,
```

```
SENSIBILITE= (E1, E2, E3, Pa, PB)))
```

*All the options of the order are obviously accessible.*

```
IMPR_RESU (RESU=_F (RESULTAT=resultat,
SENSIBILITE=
(E1,
E2,
E3,
Pa,
PB),
NOM_CHAM=
“SIEF_ELGA_DEPL”,
GROUP_MA='ZONE_3',
VALE_MAX='OUI',
VALE_MIN='OUI')
)
```

*Beyond the impression, all the orders which handle the results were equipped with key word SENSITIVITY: EXTR\_RESU, POST\_RELEVE\_T etc operation is similar to standard: the order carries out the operation required but on the selected derived fields and exclusively on them.*

## **Generals**

### **5.1**

#### ***Automation of the analysis of the orders***

*An attentive user who will consult the file of the messages produced by Code\_Aster will see that, by report/ratio from what had been requested, more orders were carried out. It is completely normal. The computing process of sensitivity needs to derive the unit from the orders where intervene the significant parameters. A preprocessing of the command set thus will duplicate each order by replacing its arguments by the derived arguments. New concepts are created, whose names are establish by an automatic mechanism. They are memorized in-house with calculation by order MEMO\_NOM\_SENSI. Their knowledge does not have any interest for the user insofar as all information is accessible by a couple (name from standard concept, significant name of parameter). In short, we can say that the maximum was made to simplify the task of the user.*

*Nevertheless, a reserve is essential: this mechanism of preprocessing is available only for treatment of the orders by batches. It is the default option besides of the order BEGINNING. Thus any command set produced by editor EFICAS by preserving the batch processing will be interpreted correctly. For a advanced use of the command set which involves the inactivation of batch processing, the automatic insertion of the derived orders does not take place. It is what occurs when one modifies with the hand the command set to insert basic Python instructions there. It is necessary then to make with the hand work derivation of the orders, the ones after the others, while memorizing names of the produced concepts.*

### **5.2 Performance**

**Note of calculation to buckling**

**Summary:**

**The objective of this documentation is to not present a methodological guide for an analysis of buckling**

**linear of a structure. One approaches mainly two functionalities of Code\_Aster there:**

- analysis of buckling linear, known as of Euler, through `MODE_ITER_SIMULT`, (option `TYPE_RESU: "MODE_FLAMB"`),**
- the calculation of the quasi-static evolution (operator `STAT_NON_LINE`) of the structure which presents not geometrical and behavioral linearities, which one seeks a limiting point, even the answer post-critical.**

**The first stage is, generally, a calculation of buckling of Euler, who will allow to know the modes of**

*buckling and corresponding critical loads. From the point of view of the originator, the knowledge of first mode and of its critical load is often sufficient, in order to be defined a margin of operation compared to the imposed loading: the multiplying coefficient enters the imposed loading and the critical load weakest the safety margin gives.*

### **Remarks**

- The knowledge of the first mode of buckling can also be used as indication to optimize management of nonlinear incremental calculation carried out thereafter. Indeed, with the approach of the load critical, one can then decide to modify piloting or to reduce the step of time, even to increase the iteration count of checking of balance in the method of residue, with each step of load.*
- The pace of the mode of buckling of Euler can also be used for to impose a geometrical defect initial on the structure, in order to make sure, amongst other things, that incremental nonlinear calculation will fork well on this mode.*

*The analysis of Euler being per linear definition, it does not make it possible to take into account relations of behavior inelastic or of the contact. It is then necessary to make a nonlinear calculation, which in quasi-static will be based on order STAT\_NON\_LINE of Code\_Aster. It is the traditional method incremental by residue in balance. The particular points of its use will be approached thereafter.*

## *1 Analyze buckling of Euler*

*The calculation of the modes of buckling within the meaning of Euler [bib5] can be done by the operator of resolution problems with eigenvalues `MODE_ITER_SIMULT` (or `MODE_ITER_INV`). Within the framework of buckling, one with following typical syntax:*

```
MODP1 = MODE_ITER_SIMULT (MATR_A = RAMEP1,  
MATR_B = RAGEP1,  
TYPE_RESU = "MODE_FLAMB",  
CALC_FREQ = _F (OPTION = "BAND",  
CHAR_CRIT = (-2.4, - 2.2,),  
DIM_SOUS_ESPACE = 80,  
NMAX_ITER_SOREN = 80,))
```

*The argument of key word `MATR_A` must be the matrix of rigidity known as material, whereas the key word `MATR_B` awaits the geometrical matrix of rigidity. If operator `MODE_ITER_INV` had been employed, the arguments of key words `MATR_A` and `MATR_B` would be the same ones.*

*For recall, the modes of buckling are the clean modes of the problem to the eigenvalues according to:*

$$(K + \mu Kg) X = 0 \quad Kx = K$$

*G X*  
*K:*

*material*

*rigidity*

*of*

*stamp*

*With*

*K:*

*géométriqu*

*rigidity*

*of*

*stamp*

*E*

*G*

*:*

*eigenvalue*

*(=  $\mu$*

*- with  $\mu$ :*

*coefficient multiplica*

*T*

*tor*

*loading*

)

*Material rigidity (or rubber band) is calculated with option “RIGI\_MECA” of CALC\_MATR\_ELEM. Geometrical rigidity is calculated starting from the stress field solution of the linear problem (option “RIGI\_GEOM” of CALC\_MATR\_ELEM). Thus should have been carried out a static linear calculation before the use of MODE\_ITER\_SIMULT for buckling.*

*If the loading is composed of a fixed part (not controlled) and of a variable part, the coefficient multiplier of the loading should not, of course, relate that to the variable part. The contribution of the other part of the loading is found in the first member. Let us note FC the fixed loading and fv the controlled loading (proportional to  $\mu$ ). The problem with the eigenvalues becomes:*

$$(K + Kg (FC + \mu fv) X = 0 \quad (K + Kg (FC) X = kg (fv) X$$

*K:*

*material*

*rigidity*

*of*

*stamp*

*K G (FC):*

*géométriqu*

*rigidity*

*of*

*stamp*

*for*

*E*

*loading*

*controlled*

*not*

*With*

*Kg (fv):*

*géométriqu*

*rigidity*

*of*

*stamp*

*for*

*E*

*loading*

*variable*

*:*

*eigenvalue*

*(= -  $\mu$ )*

*In this case, it is thus necessary to solve two preliminary linear elastic problems, to be able to calculate the two different geometrical matrices of rigidity.*

*In order to be exhaustive, the presentation will relate to a structure subjected to imposed*

*displacements*

*as well as efforts, which will be the combination of a fixed loading and a variable loading that one will control with a coefficient growing being able to lead to buckling.*

## **1.1**

### **Stage 1: Calculation (S) linear (S) preliminary (S)**

*One will be useful oneself of MECA\_STATIQUE. The structure, with a grid in elements of the type hull (elements of voluminal hulls type [bib3]), is subjected to boundary conditions of Dirichlet (CONDLIM) and of Neumann. These last break up into:*

- *WEIGHED: field of gravity,*
- *PRESPH: field of pressure imposed not controlled,*
- *PRESPS1: field of variable pressure imposed.*

*For the analysis of buckling, it is necessary to separate the constant efforts from those which variable (are controlled by a coefficient). One thus will make two linear static calculations. The first will be the case of the structure subjected to imposed displacements and the constant efforts, the second will see the structure subjected to displacements imposed and on the variable efforts.*

#### **Controlled loading:**

*RESC11P1 = MECA\_STATIQUE (MODEL = MODEL,  
CHAM\_MATER = CHMAT,  
CARA\_ELEM = CARAELEM,  
EXCIT = (\_F (LOAD = CONDLIM,),  
\_F (LOAD = PRESPS1,)),  
OPTION = "SIEF\_ELGA\_DEPL",*

*PLAN = "MOY",)*

***Loading not controlled:***

*RESC12P1 = MECA\_STATIQUE (MODEL = MODEL,  
CHAM\_MATER = CHMAT,  
CARA\_ELEM = CARAELEM,  
EXCIT = (\_F (CHARGE=CONDLIM),  
\_F (LOAD = WEIGHED),  
\_F (LOAD = PRESFH,)),  
OPTION = "SIEF\_ELGA\_DEPL",  
PLAN = "MOY",)*

*One will use the stress field to calculate the associated matrices of geometrical rigidity, for two loadings:*

*SIGC11P1 = CREA\_CHAMP (TYPE\_CHAM = "ELGA\_SIEF\_R",  
OPERATION = "EXTR",  
RESULT = RESC11P1,  
NOM\_CHAM = "SIEF\_ELGA\_DEPL",  
TYPE\_MAXI = "MINI",  
TYPE\_RESU = "VALE",)  
#  
REGC11P1 = CALC\_MATR\_ELEM (OPTION = "RIGI\_GEOM",  
MODEL = MODEL,  
CARA\_ELEM = CARAELEM,  
SIEF\_ELGA = SIGC11P1,)*

*REGC11P1 is thus the geometrical matrix of stiffness associated the variable case of loading (PRESF1).*

*Instruction manual*

*U2.08 booklet: Advanced functions and control of calculations*

*HT-66/02/003/A*

---

***Code\_Aster*** ®

*Version*

*6.4*

*Titrate:*

*Note of calculation to buckling*

*Date*

*:*

*20/12/02*

*Author (S):*

**NR. GREFFET** Key

:

*U2.08.04-A Page*

*: 4/10*

*One calculates, in the same way, the geometrical matrix of stiffness for the constant loading (WEIGHED and*

*PRESPH), starting from RESC12P1:*

```
SIGC12P1 = CREA_CHAMP (TYPE_CHAM = "ELGA_SIEF_R",  
OPERATION = "EXTR",  
RESULT = RESC12P1,  
NOM_CHAM = "SIEF_ELGA_DEPL",  
TYPE_MAXI = "MINI",  
TYPE_RESU = "VALE",)
```

#

```
REGC12P1 = CALC_MATR_ELEM (OPTION = "RIGI_GEOM",  
MODEL = MODEL,  
CARA_ELEM = CARAELEM,  
SIEF_ELGA = SIGC12P1,)
```

*It remains to calculate the matrix of material rigidity for the total loading:*

```
REMEP1 = CALC_MATR_ELEM (OPTION = "RIGI_MECA",  
MODEL = MODEL,  
CHAM_MATER = CHMAT,  
CARA_ELEM = CARAELEM,  
CHARGE = (CONDLIM, WEIGHED,  
PRESPH, PRESPS1,))
```

*All the elementary matrices are calculated, the following stage is thus their assembly:*

```
NUP1 = NUME_DDL (MATR_RIGI = REMEP1,)
```

#

```
RAMC1P1 = ASSE_MATRICE (MATR_ELEM = REMEP1,  
NUME_DDL = NUP1,)
```

#

```
RAGEP1 = ASSE_MATRICE (MATR_ELEM = REGC11P1,  
NUME_DDL = NUP1,)
```

#

```
RAGC12P1 = ASSE_MATRICE (MATR_ELEM = REGC12P1,  
NUME_DDL = NUP1,)
```

*One summons then the matrices of material rigidity (RAMC1P1) and geometrical (RAGC12P1) corresponding to the case of constant loading:*

```
RAMEP1 = COMB_MATR_ASSE (COMB_R = (_F (MATR_ASSE = RAMC1P1,  
COEF_R = 1.0,)),  
_F (MATR_ASSE = RAGC12P1,  
COEF_R = 1.0,)),)
```

*The two matrices necessary to the calculation of the modes of buckling are thus built.*

## **Stage 2: Calculation of the modes of Euler**

*He can be useful to make tests of STURM (operator IMPR\_STURM) on the interval of research on which one wants to find the cases of buckling. Thus, that will make it possible to optimize the size of the interval and*

*to control the good course of later modal calculation since one will know the number in advance of existing modes. Syntax is:*

```
IMPR_STURM (MATR_A = RAMEP1,  
MATR_B = RAGEP1,  
TYPE_RESU = "MODE_FLAMB",  
CHAR_CRIT_MIN = -2.4,
```

*CHAR\_CRIT\_MAX = -2.2,)*

*Once the interval of search for critical load of buckling chosen, one can then implement MODE\_ITER\_SIMULT as follows:*

```
MODP1 = MODE_ITER_SIMULT (MATR_A = RAMEP1,
MATR_B = RAGEP1,
TYPE_RESU = "MODE_FLAMB",
CALC_FREQ = _F (OPTION = "BAND",
CHAR_CRIT = (-2.4, - 2.2,),
DIM_SOUS_ESPACE = 80,
NMAX_ITER_SOREN = 80,),)
```

### **Notice**

*If the algorithm does not converge or if the number of modes is not that predicted by IMPR\_STURM, it can be useful to increase the values of DIM\_SOUS\_ESPACE and NMAX\_ITER\_SOREN.*

*One normalizes the modes [bib6], only while being useful oneself of the degrees of freedom of translation:*

```
MODP1 = NORM_MODE (reuse = MODP1
MODE = MODP1,
= "TRAN NORMALIZES",)
```

*The modes can then be post-treated.*

### **Remarks**

*It is essential to check that the geometrical stiffness of the selected model is well one option available in Code\_Aster (for example, it is not the case of the DKT).*

*A finer discretization leads normally to a fall of the critical loads.*

*The discretization must be ready to collect the modes of buckling, knowing that these modes can generate localised deformations (folds). The preliminary calculation of dynamic modes can constitute a first indication on the quality of the grid, although these modes can be very different from the modes of buckling.*

*The critical loads of the various modes are proportional to the Young modulus E.*

***Quasistatic nonlinear study of the structure***

*This stage is justified if the structure has strong not linearities, whose analysis of Euler cannot to hold account. The operator of resolution of the nonlinear problems into quasi-static names himself STAT\_NON\_LINE [bib7].*

*These nonlinearities can be related to the material which can have an elastoplastic behavior [bib8], as in the example which will follow. The taking into account of the contact, even of friction, is another source of nonlinearities. One can also quote the case of the following loadings, like pressure ([bib1] and [bib2] for the elements of voluminal the hulls type), which requires an approach nonlinear.*

*For the study of a structure potentially unstable or likely to know a limiting point, which be thus likely to meet a junction in solution during the evolution of the loading, it is often useful to be able to choose a branch of particular solution (often the physical solution when it is a priori defined without ambiguities). For that, the user can have to introduce a defect initial which “will force” the structure to fork on the branch of particular solution. Several methods exist to define this defect.*

- One the most adapted of is of prédéformer slightly the structure according to the pace of the mode of Euler of buckling corresponding to the branch which one wants to follow. The amplitude of this predeformation must be weak, for example less 1/10ème thickness for one mean structure. The ideal being to find the defect minimal which is compatible with one satisfactory performance of the algorithm of residue in balance. Indeed, a too weak defect can involve a difficulty of convergence of the residue, mainly in the case of one*

*piloting in effort.*

- *The geometrical defect can also be defined by experimental measurements of the real part whose geometry could not be perfect.*
- *The defect can also take the form of a disturbance of the loading (misalignment, addition of a loading located,...) or of the mechanical characteristics of material (local weakening of the Young modulus, for example). He can nevertheless be then more difficult to adapt the defect to the mode of wished buckling, especially if the structure presents relatively close modes.*

## **Notice**

*In certain cases, even on the nondisturbed problem, the loading is such as it causes desired junction.*

*One of the other particular points, related to instability, is the choice of the technique of piloting of algorithm STAT\_NON\_LINE. Indeed, traditional piloting in effort is not adapted any more because it cannot*

*to collect an unstable branch of solution. In the same way, with the approach of a limiting point, convergence with*

*piloting in effort will become increasingly difficult, the matrix of tangent rigidity becoming singular. It is then necessary to reduce the increment of load and to increase the maximum number of iteration to continue calculation.*

*There are techniques of piloting [bib9] making it possible to circumvent these numerical difficulties.*

*Among*

*methods suggested by Code\_Aster, that called by length of arc [bib12] (option TYPE=' LONG\_ARC' of the key word PILOTING in STAT\_NON\_LINE), which is adapted for instabilities of the buckling type, in the case of “soft” snap-backs possible [bib13]. In the case of snap-backs more brutal, Crisfield proposes an alternative [bib13], nonavailable in version 6 of Code\_Aster.*

*Other methods exist, like that of Riks [bib14] (nonavailable either), which treats also it dynamic case.*

*If one wants only to obtain the point limits, including with a good precision, a piloting in loading can be enough, with the proviso of managing well the parameters of step of increment of load (SUBD\_PAS and SUBD\_PAS\_MINI of the key word INCREMENT) and of maximum iteration count authorized*

*(ITER\_GLOB\_MAXI of CONVERGENCE). It can also be useful, with the approach of the limiting point, of more*

*to use the tangent matrix reactualized for the solvor, since it is quasi-singular. One can then to be satisfied not to reactualize this matrix with each calculation (parameters REAC\_INCR and The REAC\_ITER) or, in worst of the cases, to adopt the basic elastic matrix (PREDICTION=' ELASTIQUE' and MATRICE=' ELASTIQUE' of the key word NEWTON).*

*Here an example of use of STAT\_NON\_LINE for an elastoplastic calculation into large displacements ([bib4] for the elements employed, which are of voluminal hulls type), with piloting in efforts:*

```

RESU = STAT_NON_LINE (MODEL = MODEL,
CHAM_MATER = CHMAT,
CARA_ELEM = CARAELEM,
EXCIT = (_F (LOAD = CONDLIM,
TYPE_CHARGE = "FIXE_CSTE"),),
_F (LOAD = WEIGHED,
TYPE_CHARGE = "FIXE_CSTE"),),
_F (LOAD = PRESFH,
FONC_MULT = FONCMUL2,
TYPE_CHARGE = "SUIV"),),
_F (LOAD = PRESF1,
FONC_MULT = FONCMUL,
TYPE_CHARGE = "SUIV"),),),
COMP_INCR = (_F (RELATION = "VMIS_ISOT_TRAC",
COQUE_NCOU = 1,
DEFORMATION = "GREEN_GR",
GROUP_MA = ("RING", "ROOF",
"RINGS", "SGOU"),
), ),
COMP_ELAS = _F (RELATION = "ELAS",

```

COQUE\_NCOU = 1,  
DEFORMATION = "GREEN\_GR",  
GROUP\_MA = "LTIGE",),  
INCREMENT = \_F (LIST\_INST = L\_INST1,  
NUME\_INST\_FIN = 14,  
SUBD\_PAS = 4,  
SUBD\_PAS\_MINI = 1.E-9),  
NEWTON = \_F (REAC\_INCR = 1,  
PREDICTION = "TANGENT",  
STAMP = "TANGENT",  
REAC\_ITER = 1),  
CONVERGENCE = \_F (RESI\_GLOB\_RELA = 1.E-06,  
ITER\_GLOB\_MAXI = 40,  
STOP = "YES"),  
SOLVEUR = \_F (METHOD = "MULT\_FRONT",  
RENUM = "MONGREL",),)

### **Remarks**

.  
*One uses the tangent matrix reactualized with each calculation, while authorizing under step division of load.*

.  
*The imposed pressures are following efforts (TYPE\_CHARGE=' SUIV').*

.  
*In the case of a modeling in solid elements, the tensor of deformation recommended in great displacements is "SIMO\_MIEHE".*

### ***1 General information***

***The numerical method of Monte Carlo makes it possible to calculate various statistical sizes from one random variable or of a stochastic process. In the context of a mechanical calculation (or thermomechanical,...) , the principle is to obtain NS achievements of this random variable or it stochastic process then to deduce the required statistical estimates from them. Three principal stages of the Monte Carlo method are:***

- 1) Generation of a sample of NS achievements of the random data of entry of the model mechanics,***
- 2) Calculation***

***NS sizes results corresponding to these data,***

- 3) Calculation of the statistical estimators of the required sizes.***

***In the Monte Carlo method simple or direct that one uses, each NS calculations can be fact independently of the others. In order to reduce the size memory necessary, the NS generations and calculations are thus carried out sequentially in a loop with destruction of the results useless intermediaries.***

## ***2***

***Buckle Python in the command file Aster***

***In order to allow the use of a loop python in the command file, it is first of all necessary to position key word PAR\_LOT of the order BEGINNING on the value "NOT":***

***BEGINNING (CODE=\_F (NAME = "SDNS001"), PAR\_LOT='NON')***

*The loop python in it even starts with the order for, and includes all the lines of even indentation*

```
for K in arranges (1,1000):  
  COMMANDE1  
for m in arranges (1,500):  
  COMMANDE2  
  COMMANDE3
```

*In this example, one finds two loops python encased. The first, on the variable K, allows to carry out 999 times instructions COMMANDE1, the second loop python, and COMMANDE3. second internal loop python, on the variable m makes it possible COMMANDE2 to be carried out 499 times for each K going from 1 to 999.*

### ***Notice***

*There is no instruction of end of loop. The indentations alone mark the body of the instruction “for”.*

### **3** **Generation of random variables**

*The terminology of random generators must here be taken in the broad sense. These random variables can be with values scalar, matric, or even functional calculuses (stochastic process).*

*Code\_Aster is able to generate of such random variables respectively by the orders GENE\_VARI\_ALEA, GENE\_MATR\_ALEA and GENE\_FONC\_ALEA.*

*The random variables can be parameters of the model finite elements (parameters materials, values of a play, a stiffness of thrust rubber bands, a modulus Young, etc). In it case one models uncertainties of modeling by a parametric probabilistic approach and one use GENE\_VARI\_ALEA then.*

*In dynamics of the structures, these random variables can also be the generalized matrices of mass, stiffness and damping and/or local parameters of the model to the finite elements. In this case, one models at the same time uncertainties of model and modeling by an approach not-parametric probabilist, and GENE\_MATR\_ALEA is used.*

*These random variables with scalar or matric values follow laws of built probabilities by the use of the principle of the maximum of entropy and information available (see [R4.03.05]).*

*The random variable can still be a function. Operator GENE\_FONC\_ALEA allows to generate trajectories of a monodimensional multivariate stochastic process (i.e with several components and indexed on only one variable) stationary of null average starting from its density spectral of power. In the case of a transitory dynamic calculation, one can thus generate temporal loadings known by their matrix interspectrale.*

*With less than one contrary indication using key word INIT\_ALEA, all the values generated by*

*three orders GENE\_VARI\_ALEA, GENE\_MATR\_ALEA and GENE\_FONC\_ALEA are statistically independent between them inside the same execution of Code\_Aster. A contrario, of one execution with the other, a strictly identical command file (even calls to the three orders in the same order with the same arguments) will provide the same ones exactly results. If one wishes to generate results statistically independent of an execution with the other, then it is necessary to use key word INIT\_ALEA with values raising the number of terms used in the former executions.*

**Caution:**

*The generator of random variable used is that of the module “random” of Python. It depends on the version of Python exploited by Code\_Aster. Not converged results statistically can thus vary from one version to another of Code\_Aster or one platform with the other, if the version of Python is not the same one and that between the two poured the module random evolved/moved (case between Python 2.1 and 2.3).*

**Note:**

*In version Python 2.3, the period of the generator is  $2^{**} 19937-1$  (Mr. Matsumoto and T.*

*Nishimura, Mersenne Twister: With 623-dimensionally equidistributed uniform pseudorandom number generator, ACM Transactions on Modeling and Computer Simulation vol. 8, No 1, January pp.3-30 1998.)*

**Note:**

*The module “random” of Python provides an alternative to order GENE\_VARI\_ALEA to generate random variables of which the densities are not available in this order.*

**4 Estimators statistics**

*Of a sample of NS achievements of the quantity of interest, one can deduce the estimates from them from statistical sizes like the average, the standard deviation,... The estimators must in general be calculated in two times. Initially, inside the loop of the intermediaries quantity then in a second after the loop the estimators are calculated to them-even.*

4/8

*Let us take for example a sample of spectra of oscillators  $\{SRO (; p)\}_{1 \leq p \leq NS}$ , for which for each pulsation we wish to calculate the moments of order 1 and 2. These moments have for expression:*

*1 NS*

*m (,) =*

*SRO (,),*

*1*

*p*

*NS p 1=*

*1 NS*

*2*

*m (,) =*

*SRO (,).*

*2*

*p*

*NS p 1=*

*The two sums above are easily calculable inside the loop, it is simply necessary to differentiate the case from the initialization of the sum and the cases of incrementing from this*

*summon.*

*Here, for example, a command file purified allowing to evaluate m (,):*

*2*

*for K in arranges (1, ns+1):*

*MATM=GENE\_MATR\_ALEA (MATR\_MOYEN=MASSE, DELTA=0.2)*

*MATK=GENE\_MATR\_ALEA (MATR\_MOYEN=RIGID, DELTA=0.2)*

*MATD=GENE\_MATR\_ALEA (MATR\_MOYEN=AMORT, DELTA=0.2)*

*generation of one*

*CALC\_FONCTION. Sum SRO (, p) 2*

*,  
is stored, with the fur is as them*

*achievements are produced, in M2\_3 using key words POWER and COMB of order CALC\_FONCTION, intermediate functions M2\_0 and M2\_1 and order TO DESTROY. All various produced concepts (MATM, MATK, MATD, DYNA, SPO, A CC1, etc) must be destroyed at the end of each iteration except for M2\_3, of course. Lastly, one time the NS iterations carried out, the function  $m(,)$  is evaluated and corresponds to the object*

*2  
M2  
product at the end of the example.*

**Note:**

*When order GENE\_FONC\_ALEA is used, there is the possibility of not to use of loop python. The principle is then to generate “end to end” several temporal (key word NB\_TIRAGE in GENE\_FONC\_ALEA) and post-to treat the results with order CALC\_INTE\_SPEC. Case-test ZZZZ180 [V1.01.180] gives an example of such a use.*

**5**  
*Example in transitory dynamics*

**Principle of deterministic calculation**

*One is based on the SDNS01a case-test concerning the response of a rectangular plate with one*

*butted elastic subjected to a deterministic impulse load.*

*One builds the solution of the average dynamic model reduced (determinist) using one traditional sequence operators (ASSE\_MATRICE, MODE\_ITER\_SIMULT, MACRO\_PROJ\_BASE ....)*

*One is interested in the answer of the system calculated by DYNA\_TRAN\_MODAL, and more exactly with*

*standardized spectra of the answers and with the temporal observations (fields of displacement, speed, acceleration, constraints, etc).*

### ***Principle of probabilistic calculation***

*The stiffnesses of thrusts are made random as well as the generalized matrices of mass, of stiffness and of damping.*

*The achievements of the corresponding stochastic transitory answer are calculated by the method of digital simulation of direct Monte Carlo with NS simulations using a loop Python the structure is:*

### ***Beginning buckles, for $p = 1, \dots, NS$ :***

*has) Generation of the pième achievements of the random variables (parametric approach) with assistance of GENE\_VARI\_ALEA.*

*Generation of the pième achievements of the random generalized matrices of mass, of stiffness and of damping using GENE\_MATR\_ALEA (nonparametric approach).*

***These matrices are not diagonal and thus require a full storage.***

*b) Calculation of the pème realization  $Q_n(T; p)$  solution of the stochastic matrix system with non-linearities of shocks, entirety  $N$  being the dimension of the small-scale model. This realization is the solution of the traditional matrix system whose matrices are the achievements previously generated. Calculation is thus carried out by DYNA\_TRAN\_MODAL.*

*c) Extraction of the physical ddls in displacement  $\&Z N(T; p)$  for preset ddls, via I operator RECU\_FONCTION.*

## *1 Synthesis*

*The tool-trade ASPIC makes it possible to carry out analyses of harmfulness of defect in prickings of the CSP.*

*This tool is composed of an automatic maillor of pricking and a solvor for the analyses thermoelastic linear. It is entirely integrated into Code\_Aster. The maillor is usable independently of the solvor.*

*This note aims to describe methodology for the realization of an analysis of harmfulness of defect with the tool trade ASPIC. One also endeavours to list in an exhaustive way the unit of data input ASPIC. One has in version 6.4 of Code\_Aster two macro-orders, one corresponds to the automatic maillor (MACR\_ASPIC\_MAIL), the other with the procedure of calculation itself (MACR\_ASPIC\_CALC).*

*To inform these macro-orders, it is necessary to have information on:*

- geometry of pricking,*
- boundary conditions and loadings applied at the ends (end of the pipe*

*connected BRANCH or ends of body RUN, R1 or R2),  
· the characteristics materials.*

*The results provided by the macro ordering of calculation are useful, by comparison with the criteria codified, to rule on the harmfulness or not of a defect characterized during a control.  
This document constitutes the methodological reference frame of a study of harmfulness of defect with ASPIC.*

*One finds there a description exhaustive of the data input for the macro-orders of the tool trade ASPIC. The construction of these data starting from the data provided in the DAC is entirely clarified. Finally the description of a study of analysis of harmfulness of defect on a pricking is detailed. Examples illustrate each phase of setting in data and the type of awaited result during an analysis of harmfulness.*

## *2 Introduction*

### *2.1 Context*

*The tool-trade ASPIC makes it possible to carry out analyses of harmfulness of defect in prickings of the CSP.*

*This tool is composed of an automatic maillor of pricking and a solvor for the analyses thermoelastic linear. It is entirely integrated into Code\_Aster. The maillor is usable independently of the solvor.*

### *2.2*

*Objective of the note*

*This note aims to describe methodology for the realization of an analysis of harmfulness of defect with the tool trade ASPIC. One also endeavours to list in an exhaustive way the unit of data input ASPIC.*

*This note is based on the note written by J.P. SERMAGE, reference [bib1].*

### **2.3 Step adopted**

*This reference frame must make it possible to implement analyses of harmfulness of defects according to rules'*

*in conformity with the RSE-M [bib4]. The method of plastic correction applicable is the Kcp method. One*

*have in version 6.4 of Code\_Aster [bib5] two macro-orders, one corresponds to automatic maillor (MACR\_ASPIC\_MAIL), the other with the procedure of calculation itself (MACR\_ASPIC\_CALC).*

*To inform these macro-orders, it is necessary to have information on:*

- geometry of pricking,*
- boundary conditions and loadings applied at the ends (end of the pipe connected BRANCH or ends of body RUN, R1 or R2),*
- the characteristics materials.*

*The results provided by the macro-order of calculation are useful, by comparison with the criteria codified, to rule on the harmfulness or not of a defect characterized during a control.*

### **2.4 Plan of the note which results from this**

*The plan of the note follows the total step of an analysis of harmfulness of defect with the tool trade ASPIC.*

*Chapter 3 presents the data input of the tool trade ASPIC.*

*Chapter 4 described how to build starting from the DAC the data input ASPIC.*

*Chapter 5 points out the principle of an analysis of harmfulness of defect.*

**Data input ASPIC**

### **3.1 Geometry of the grid**

**Information relating to the geometry of pricking is used to inform the macro-order MACR\_ASPIC\_MAIL [bib12]. The concept produced by this macro-order is of grid type. It contains the topological entities allowing:**

- to apply the boundary conditions and the loadings;**
- to strip the results.**

**Zmax**

**LZmax**

**½ DEXT\_TUBU**

**E\_TUBU**

***Center body***

***Appear 3.1-a: Description of the geometrical parameters (welding of type\_2)***

***Initially, order EXEC\_MAILLAGE makes it possible to establish the link with the software GIBI which is used to produce the grid. Parameters like: COEF\_MULT\_RC1, COEF\_MULT\_RC2,..., NB\_SECTEUR,..., RAYON\_TORE, make it possible to optimize the quality of the grid (nonexhaustive list). Then, one informs the state of refinement of the grid desired close to the welding, it can be coarse (2 nodes on the saddle and 3 nodes on the interface) or end (3 nodes on the saddle and 7 nodes on the interface).***

***“LARGE” · (default option)***  
***· “FINE”***

***One recommends the “LARGE” option for the fissured grids, the block fissures being sufficiently refined and the option “END” to carry out an analysis of harmfulness of healthy defect on prickings [bib7].***

***Concerning the pipe, the geometrical parameters to inform are:***

- *the thickness of the pipe in the zone of connection (E\_BASE), (reality, mm),*
- *the diameter external of pipe (DEXT\_BASE), (reality, mm),*
- *the length of the base of pipe (L\_BASE), (reality, mm),*
- *the length of chamfer (L\_CHANF), (reality, mm),*
- *the thickness of the pipe above chamfer (E\_TUBU), (reality, mm),*
- *the diameter external of the pipe above chamfer (DEXT\_TUBU), (reality, mm),*
- *the maximum dimension of pipe (Z\_MAX), (reality, mm),*
- *the type and the position of welding (TYPE\_1 or TYPE\_2).*

*The type and the position of the welding are of type\_1 if the bevel of the welding is located in the body [Figure 3.1-a], of type\_2 if the bevel of the welding is located in the pipe.*

*The welding is located by:*

- *the height of welding counted with part of external surface (H\_SOUD), (reality, mm),*
- *the angle of welding (ANGL\_SOUD), (degrees),*
- *play of the welding characterized by the space located between the body and pipe (JEU\_SOUD), (reality, mm).*

*Finally the body of pricking is defined by:*

- *the thickness of body (E\_CORP), (reality, mm),*
- *the diameter external of body (DEXT\_CORP), (reality, mm),*
- *the maximum dimension of body (X\_MAX), (reality, mm).*

*If analyzed pricking comprises a crack, it is also necessary to define the characteristics of the crack:*

- *the type of the crack (long or short).*

*The long cracks correspond to long but not very deep cracks (1/8 or 1/4 thickness), the short cracks correspond to cracks of maximum depth equal to the half thickness pricking.*

- *depth of the crack (DEPTH), (reality, mm),*
- *the length of the crack (LENGTH), (reality, mm),*
- *the position of the center of the crack (AZIMUTH), (degrees),*
- *the position (right or tilted) according to the type of the welding (POSITION), [Figures 3.1-b] and [Figure 3.1-c],*
- *the position emerging in internal or external or non-opening skin (CRACK),*
- *the length of the interior ligament (crack not emerging) (LIGA\_INT), (reality, mm),*
- *the half angle of opening of crack (ANGL\_OUVERTURE), (degrees).*

**U2.09.01-A Page**

**: 8/20**

**To ensure the balance (BALANCE) of the structure, one defines an embedding of the beam type in the one of the two ends of the body (R1 or R2). This choice depends the definition on the torque of the efforts with**

**to apply at the ends (R1 or R2 and B).**

**One indicates then the value of the pressure (PRES\_REP) which applies in internal skin (MPa), with taking into account of the basic effect on the faces associated at the end with the pipe B and one with two faces ends of the body (R1 or R2).**

**The torque of effort is applied at the ends B of the pipe and (R1 or R2) of body (TORS\_CORP, TORS\_TUBU).**

**One informs the 6 components of the torque of efforts:**

- force according to X FX (NR)**
- force according to Y FY (NR)**
- force according to Z FZ (NR)**
- moment according to X MX (N.mm)**
- moment according to Y MY (N.mm)**
- moment according to Z MZ (N.mm)**

*For thermal calculations (EXCHANGE), one indicates the value of the coefficient of exchange (W/mm<sup>2</sup>) on skin interns pipe and body, as well as the value of the temperature of the fluid (°C) inside pricking for various moments of the transient. One will see in chapter 4 how to build this torque of effort starting from the DAC (File of Analysis of Design).*

### **3.3 Materials**

*The definition of materials is done apart from macro-order MACR\_ASPIC\_CALC, but their assignment is done in the macro-order by key word AFFE\_MATERIAU. Data material either are taken at temperature given (ambient or average of the transient), or function of the temperature (case general). When these data depend on the temperature, they are stored for a list of temperatures. They come is: RCC-M [bib10], RSE-M [bib4] or of specific measurements.*

*The data necessary to the definition of material are:  
data of behaviour in traction*

- modulus Young E (MPa)*
- Poisson's ratio*
- dilation coefficient (°C<sup>-1</sup>)*
- thermal conductivity (W.mm<sup>-1</sup>°C<sup>-1</sup>)*
- density (kg.mm<sup>-3</sup>)*

*One also notes the importance of the definition of the temperature of reference for which there is not no thermal deformation.*

## 4

***Calculation of line to the analysis of harmfulness of defect***

## 4.1

***Calculations of lines: general information***

***A calculation of line consists in determining torques of effort and displacements and checking them criteria of design defined in the RCC-M [bib5].***

***The rules of layout used by the manufacturer are such as pipings are primarily solicited in pressure and inflection whatever the loading. The criteria of design relate to constraints due to the pressure and on those generated by the torsion and bending moments, thus that by the basic effect.***

***In a general way, an auxiliary line and its pipings are represented by a telegraphic model or beam from isometric in the plan. The components are modelled according to their stiffness and their mass respective: self-supporting quality, valves, valves, prickings.***

***Within the framework of an analysis of harmfulness of defect in a component, one uses in data input torques resulting from the calculation of line. These torques known as “are signed” or “not signed”.***

***The torque is signed when it is defined perfectly by its direction, its sign and its amplitude.***

***Typically, they are the loadings of the weight type, pressure or thermal dilation. The torque is not signed when it is defined only by its maximum amplitude and its direction. It is the case of alternative loadings like a rupture of piping or a seism. For the mechanical analysis of pricking, the data of the DAC to be extracted are the torques calculated with the node of the line which represents***

***the intersection between two portions of line.***

## 4.2

***Definition of the loading ASPIC starting from the DAC***

***The space modeling of a line of piping using elements beams makes it possible to determine in each modelled node the mechanical torques which result from the whole of the situations from operation studied. These torques are available in the DAC, whose extract is given in [bib14].***

***The signed loadings are traditional mechanical efforts, they are practically balanced. By against the not signed loadings are not real efforts but only the terminals higher of each component. They are not balanced.***

***To define the mechanical efforts several stages are necessary, they are described in following paragraphs.***

***4.2.1 Stage 1: change of reference mark***

***In modeling space beam, pricking corresponds to a node of the grid which is the point commun run with three beams. Mechanical torques calculated in this node for each beam***

**allow to know the efforts to be applied at the ends R1, R2 and B of pricking. Like locate local related to each beam or the total reference mark “manufacturer” in whom mechanical torques**

*are calculated does not correspond to the reference mark of pricking, this first stage consists in carrying out one*

*change of adequate reference mark in order to determine the mechanical torques in the reference mark of pricking*

*(0, X, Y, Z). With the exit of this change of reference mark, the components of the mechanical torques are*

#### **4.2.2 Stage 2: rebalancing of the torques**

***Because of precision of calculations related to the discretization of the line of piping, torques mechanics which one calculates is not rigorously balanced. Correction suggested here consist in rebalancing torques by average value.***

***To rebalance the torques by average value consists in modifying each component according to following formulas:***

**FR1**

**FR**

**1**

**1**

**FR1**

**FR2**

**BFR**

**2, I =**

*Real efforts defined by the equations [éq 4.2.3-1] [éq 4.2.3-2] and [éq 4.2.3-3] can be applied directly at the ends R1, R2 and B of fissured pricking. In ASPIC one of ends of the RUN is embedded (R1 or R2). The torque of effort defines in the paragraph [§3.2] is [éq 4.2.3-3] for the end of the pipe and [éq 4.2.3-1] or [éq 4.2.3-2] for the end of the body.*

#### **4.2.4 Stage 4: obtaining the maximized loading**

*The ultimate stage consists in defining the maximized loading. The maximized loading is the loading corresponding to the combination of the signed loading and not signed such as the rate of refund of energy, noted local Gmax is maximum for a given crack.*

*Two methods of calculation of Gmax are available, analytical described in [bib13], the other numerical and established in Code\_Aster.*

*The analytical method relates to the loading not signed and consists in seeking that which maximizes the mode of opening I. the REX [bib15] shows that his implementation is tiresome, also one recommend the use of the numerical method. An example of the implementation of the method analytical is given in [bib8]. This example made it possible to validate the analytical method by comparison between the result and the numerical method of reference.*

*The numerical method established in Code\_Aster examines the three possible couples of constraints and the minimum of maximum retains reached (conservative solution compared to the exact solution).*

*In other words, one calculation three Gmax, the first starting from the torques defined at the end of the RUN (R1 and R2), the second starting from the torques defined in the one of the end of the RUN and the end of the BRANCH*

*(R1 and B), the last is the combination (R2 and B). An example of the implementation of the method numerical is given in [bib9].*

*It is possible to maximize the mechanical loading in its totality, in which case, it is enough to calculate*

*the amplitude of the total loading as being the sum of the amplitudes of the loading signed and of loading not signed. The result of [bib8] shows that this way of making is conservative by report/ratio with the case or only the loading not signed is maximized.*

### **4.3 Application**

**The following table gives the elementary loadings to the center of pricking (raised in the DAC) participants in the situation of category 2. The signed loadings are cumulated linearly between them, the loadings not signed as for them are cumulated quadratically. These loadings must to be affected of a safety coefficient of 1.5.**

**In each category, the situations are obtained by the following combinations, for example in 2nd category: 1 17 18 19 max (14, 15, 16) 2 6 7 8 to 13**

**Heading number**

**Nature**

**Actual weight**

**1**

*An example of maximization of the mechanical loading is given in [bib8] and [bib9].*

5

*Analyze harmfulness of defect on a pricking*

*The sizes which one uses in breaking process are the stress intensity factors for each mode of opening of the defect and the rate of refund of energy. The rate of refund of energy  $G$  is calculated whatever the mode of request (opening or closing) of the crack.*

## **5.1 Principle**

*Two methods can be implemented starting from the results of the execution the macro one order calculation. One, or one compares the rate of refund of elatoplastic energy  $G (= JEF)$  with the fissuring force  $J_{0,2}$  of material. If the  $J_{0,2} \text{ ratio}/JEF > 1$ , it does not have risk of brutal rupture there.*

*The other, or calculation is elastic, one then applies the analytical method of plastic correction. In the case of a mechanical loading combining and thermics it consists of a rule of office plurality between the method  $K_{cp}$  and  $J_{th}$ . In mechanics alone, the method codified in the RSE-M is the method*

*$K_{cp}$ .*

*The study of the correction of plasticity under mechanical loading only ( $1/Kr$ ) is considered to be too complex,*

*the geometry itself of prickings does not allow the  $Lr$  calculation (indicating of the level of plasticity in mechanics). Moreover one standard validation [bib10] would require many calculations finite elements in elastoplasticity.*

## **5.2**

*Output data ASPIC*

*Postprocessings of calculation ASPIC must make it possible to implement analyses of harmfulness*

*of defect in accordance with the RSE-M such as:*

- transformation of stress fields into stress intensity factors by the method functions of influence*
- calculation of the correction of plasticity and checking of the field of validity.*

*For healthy prickings, the constraints of opening according to modes I, II and III are calculated. Via operand RCCM, one can carry out a postprocessing of type POST\_RCCM, precautions are with to take at the time to define the characteristics material [bib12].*

*The rate of refund of density of energy, noted G, is calculated according to the curvilinear X-coordinate on*

*bottom of crack and according to time. It is this value which is to compare with the fissuring force  $J_{0,2}$  material for evaluation of the factors of margin.*

### *5.3 Coding*

*The criteria to be applied for the specific studies of the defects are codified in the appendix 5.6 IV 2 of RSE-M [bib4] for the materials of level 2.*

*The fissuring force  $J_{0,2}$  of material to the starting of the tear corresponds conventionally to one ductile extension of 0,2 Misters For example for the base metal standard A48 or A42 and the welded joints,*

*these values are:*

- $J_{0,2} = 92 \text{ KJ/m}^2$  for a lower temperature or equalizes with  $100^\circ\text{C}$*
- $J_{0,2} = 55 \text{ KJ/m}^2$  for a higher temperature or equalizes with  $200^\circ\text{C}$*

*The values of  $J_{0,2}$  can be to interpolate linearly between  $100^\circ\text{C}$  and  $200^\circ\text{C}$*

### *5.4 Example of application*

*One finds examples of use in the documents [bib8], [bib9].*

*One summarizes in the table according to the results of the analysis of harmfulness of defect on pricking*

*ANG-ASG of stage CP0-BGY [bib9].*

**6**

**Application or conditions of use of the results**

**The plastic designs must be reserved for the mechanical analyses of type appraises because of associated computing time (see appendix). Preparation of the data input for the macro ones orders of ASPIC requires much rigour. A REX [bib15] of work practise with ASPIC showed that the preparation of the loadings and obtaining the maximized loading take 2 with 3 working days for an engineer. To obtain the maximized loading, one recommends to use numerical method of calculation of local Gmax.**

**For the calculation of the fissuring force, one recommends the use of the analytical method as in [bib8] and [bib9]. For that it should beforehand be checked that the applicability is included/ understood in**

**field of validity of the methods codified in the RSE-M [bib4].**

### **Healthy grid**

*For the thermal transients, it is necessary to use a refinement says "FINE" grid. To strip the elementary stress fields under loading, it is necessary to strip in plans spaced to the maximum of 15°. That is to say 24 plans on the whole for ASPIC.*

### **Geometry of the welding**

*The geometry of the welding has an influence: the covered total angle and the external extra thickness. For the angle, them two interfaces welding body and welding pipe constitutes extreme positions and also give results which wrap all the intermediate plans. As for the extra thickness, one cannot conclude from way reliable only starting from the results presented here. One will conclude in a very total way by saying that more this extra thickness is small, less there is matter and thus more one places oneself in a geometrical configuration penalizing.*

### **Elastic design**

*The macro ordering of calculation ASPIC calls upon solvor STAT\_NON\_LINE. Default options of it solvor implies an actualization of the matrix of rigidity to each increment, which is expensive in times of calculation (1000s with each resolution) if one must calculate several steps of loading (case of a transient thermics) and useless for an elastic analysis. Consequently, it is absolutely necessary to indicate in the macro one order calculation ASPIC the option:*

*SOLVEUR = \_F (  
REAC\_INCR = N,*

*N > a number of total increment of calculation*

*STAMP = "TANGENT",*

*REAC\_ITER = 0),*

### **Elastoplastic calculation**

*These calculations are very long and very expensive. Various options were used under the key word NEWTON:*

:

*U2.09.01-A Page*

*: 18/20*

***OPTION 1:***

*NEWTON =\_F (MATRIX = "ELASTIC"),*

*· Calculation converges very slowly (more than 10 iterations for an increment), much more slowly than with a TANGENT matrix.*

***OPTION 2:***

*NEWTON =\_F (REAC\_INCR = 1,*

*STAMP*

*=*

*"TANGENT",*

*REAC\_ITER = 1),*

*RECH\_LINEAIRE =\_F (RESI\_LINE\_RELA = 1.0E-3,*

*ITER\_LINE\_MAXI = 3),*

*· So that calculation converges with a reasonable iteration count (3 to 4 iterations by increment of time) it is necessary to bring up to date the tangent matrix with each increment.*

*· The use of the linear option of research does not seem to modify much computing time. The linear coefficient of research is very close to 1.*

**Instruction manual**  
**U2.09 booklet: Tools and Solutions Trades**  
**Document: U2.09.02**

**Realization of the calculation of an assembly pin-attaches**

## **1 Goal**

**This note concerns, the realization of the grid and of the total calculation of an assembly pin-attaches with**

**Code\_Aster.**

**Calculations themselves as well as the macro-orders evoked in this document are available in the command files of cast-test ZZZZ120A and ZZZZ120B.**

*The production of the grid requires the use of the function MACR\_GOUJ2E\_MAIL which must be defined in the beginning of the command file. On the other hand, calculation is carried out only with orders of Code\_Aster. Macro-order POST\_GOUJ allows the presentation of the results in a format which facilitates their reading. Like function MACR\_GOUJ2E\_MAIL, this macro order must be defined in the beginning of the command file. Calculation also requires the use of the data base containing the geometrical and mechanical characteristics assemblies.*

*We give the contents of the base in its version 1.00 of the 16/09/1999 which was produced by Department MMN starting from the old base (“gouj2ech.base\_v1\_11” version 1.09 of the 9/6/1997) qualified by the UTO, and we briefly point out the manner of feeding this new base of data.*

*This base is conceived so that the contribution of new data, characterizing new situations local, can be carried out easily.*

## **2 Introduction**

*This note concerns, the use of the function `macr_gouj2e_mail` and the macro-order `POST_GOUJ` which allows, respectively, to carry out the grid of an assembly pin-attaches and post-to treat the results of a mechanical calculation carried out with the traditional orders of `Code_Aster`. Calculation also requires the use of the data base containing them geometrical characteristics and mechanics of the assemblies.*

*Initially we describe the function `macr_gouj2e_mail` and the macro-order `POST_GOUJ`. The text of these macro-orders as their catalogues are available in command files of case-tests `ZZZZ120A` and `ZZZZ120B`.*

*In the second part we detail the contents of the profile of study and the command file. Us let us continue by specifying the manner of using the function `macr_gouj2e_mail`, the macro-order `Traditional POST_GOUJ` and orders to carry out the grid and the total calculation of an assembly pin-attach. To finish, we describe the contents of the file of results (`.resu`) before approaching quickly contents of the file of message (`.mess`).*

*The last part is devoted to the data base of the geometrical characteristics and mechanics of the pins. We follow the curves of behavior of the nets like the organization of the various data. We give the contents of the base in its version 1.00 of 16/09/1999 which was produced by Department MMN. Lastly, we briefly point out the manner to feed this data base.*

**Description of macro order POST\_GOUJ**

**4.1 Drank**

**of**

**POST\_GOUJ**

**To carry out the post treatment in a specific format.**

**To transform a table created by POST\_RELEVE\_T into a table of a specific format of type table\_sdaster. The table of the table\_sdaster type contains parameters “NUME\_FILET”,**

**“NODES”** (number of node corresponding to the number of net), **“NUME\_ORDRE”** (correspondent with the increment of load), **“REACTION”** (reaction of the nets) and **“REACTION\_CUM”** (reaction cumulated of nets in %).

*Product a structure of data of the table\_sdaster type.*

## 4.2 Syntax

**ntab [table\_sdaster]**

=

**POST\_GOUJ**

(

**COUNT =**

**tabl\_post\_rele**

,

**[TXM]**

)

## 4.3 Operand

### 4.3.1 Operand

**COUNT**

**COUNT**

= **[TXM]**

*This operand makes it possible to indicate the name of the table of the tabl\_post\_rele type which one wants to modify.*

## ***Realization of the calculation of an assembly pin-attaches***

***In this part one indicates the manner of using the function `macr_gouj2e_mail`, the macro one order `POST_GOUJ` and the orders of `Code_Aster` to make a total calculation of an assembly pin-attach. One will start by describing the profile of study (file `.astk`), one will continue while clarifying***

***contents of the message and result, command files (file `.com m`) (file `.resu`) (file `.mess`). The contents of the data base (logical unit 38 free format) are described in [§6].***

5.1

### ***Profile of study***

***In the profile of study, only two files are obligatory in data: the command file (file `.com m`) and the file containing the data base (logical unit 38 free format). The file containing the grid (file `.mail`) is automatically produced and is not visible by the user. Nevertheless, this last can visualize the grid produces by putting in result the file “grid Gibi, (`mgib`)” corresponding to the logical unit 53, and while using in the command file order `IMPR_RESU` as indicated in the paragraph [§ 5.2.2].***

***The file of results (file `.resu`) makes it possible to exploit the results.***

**Note:**

*The preceding lines are present in the cases tests ZZZZ120A and ZZZZ120B, it will thus be necessary to recopy at the beginning of all new command file.*

*Then the command file will have to contain the orders and the sets of orders in the order indicated below:*

- 1) **BEGINNING ()**
- 2) **INCLUDE ()**
- 3) *email = {Together of orders which produce the grid. }*
- 4) *calc = {Together of orders which carry out calculation. }*
- 5) **END ()**

**5.2.1 Detail of order INCLUDE**

*The syntax of order INCLUDE is as follows:*

**INCLUDE (UNIT = 38,)**

*The Logical number of Unit (38) corresponds to the file containing the data base, cf [§5.1].*

**5.2.2 Production of the grid**

*The function macr\_gouj2e\_mail, cf [[§3] and the whole of orders described low ensure production of the grid of an assembly pin-attaches such as that which is presented on [Figure 3.3-a]. Except order IMPR\_RESU, They all are necessary.*

- 1)  
*function*  
**macr\_gouj2e\_mail;**
- 2)  
*line*  
**loc\_outils=aster.repout ();**
- 3)  
*order*  
**EXEC\_LOGICIEL;**
- 4)  
*order*  
**PRE\_GIBI;**
- 5)

**order**

**MAIL=LIRE\_MAILLAGE;**

**6)**

**order**

**MAIL=DEFI\_GROUP;**

**7) optional order IMPR\_RESU.**

**Order EXEC\_LOGICIEL launches the Gibi software which generates the file of grid to the format Gibi (file .mgib) starting from the data files Gibi (file .datg) to which the user does not have access.**

**The function macr\_gouj2e\_mail is used to recover in the data base the ray interns attach, the external ray of the pin and the step of the nets of the pin characterized by its type and its alternative,**

**cf [§3]. Moreover this function prepares the data files Gibi (.datg). Characteristics geometrical of the support and the nets are specified by the means of operands H\_CORP\_BRID (Height of the Body of Support, part of the support in catch with the nets) and R\_EXT\_BRID (Ray Outside of the Support) which is obligatory. Operands H\_HAUT\_BRID (Height Top of Support) and H\_BAS\_BRID (Height of the Bottom of Support) are optional, they are worth zero per defect. All them**

**dimensions must be given in millimetres. If the user gives values to the heights of high of support and the bottom of support, those cannot be lower than 1 millimetre. The ray intern of the support, the external ray of the pin as well as the step or the height of a net is sizes characteristic of a given assembly which are stored in the base; they are not, consequently, to inform by the user.**

**One indicates the total and theoretical number of nets with single-ended spanner word obligatory NB\_FILET. If**

**some of the nets miss or missing, single-ended spanner word FILET\_ABST makes it possible to indicate some**

**list. The nets absent are not with a grid.**

### ***5.2.3 Realization of calculation***

*Before writing the part “calculation” of the command file, it is advised to consult the base data in order to know the types of nets, materials and the diagrams traction which are associated a type of assembly pin-attaches given.*

*The realization of calculation requires the sequence of the following orders of Code\_Aster:*

- 1)  
order  
DEFI\_GROUP which enriches the grid by creating groups by nodes;*
- 2)  
order  
AFFE\_MODELE which assigns the mechanical phenomena to the various groups meshes;*
- 3)  
order  
AFFE\_CARA\_ELEM which makes it possible to define the section of the beam which models it pin and the characteristics of discrete which model the nets;*
- 4)  
order  
DEFI\_MATERIAU which makes it possible to define materials of the nets of the pin;*
- 5)*

**order**  
**AFFE\_MATERIAU** which affects materials defined in the groups of meshes  
adequate;

6)

**order**  
**AFFE\_CHAR\_MECA** which affects the boundary conditions and the loading;  
7) the order **DEFI\_FONCTION** which defines the multiplying function to apply to  
loading;

8)

**order**  
**DEFI\_LIST\_REEL** which defines the list of moments;

9)

*order*

*STAT\_NON\_LINE which carries out calculation;*

*10) the order CALC\_NO which calculates the nodal forces;*

*11) the order POST\_RELEVE\_T which recovers the relevant results;*

*12) the macro-order POST\_GOUJ which reorganizes the results in the adapted format;*

*the 13) order IMPR\_TABLE which makes it possible to print the results.*

*Concretely that results in the following orders:*

```
MAIL=DEFI_GROUP (reuse =MAIL,  
MAILLAGE=MAIL,  
CREA_GROUP_NO= (_F (GROUP_MA=' GOUJON',  
NOM=' GOUJ_NO',  
CRIT_NOEUD=' TOUS',),  
_F (GROUP_MA=' FILETS',  
NOM=' FILET_NO',  
CRIT_NOEUD=' TOUS',),  
_F (GROUP_MA=' BRIDE',  
NOM=' BRIDE_NO',  
CRIT_NOEUD=' TOUS',),),),);
```

```
modele=AFFE_MODELE (MAILLAGE=MAIL,  
AFFE= (_F (GROUP_MA=' GOUJON',  
PHENOMENE=' MECANIQUE',  
MODELISATION=' POU_D_E',),  
_F (GROUP_MA=' FILETS',  
PHENOMENE=' MECANIQUE',
```

```
MODELISATION='2D_DIS_T'),  
_F (GROUP_MA=' BRIDE',  
PHENOMENE=' MECANIQUE',  
MODELISATION=' AXIS',),),);
```

*REGM155A is the ray external of the pin of the type M155 alternative A.*

```
carael=AFFE_CARA_ELEM (MODELE=modele,  
POUTRE=_F (GROUP_MA=' GOUJON',  
SECTION=' CERCLE',  
CARA=' R',  
VALE=REGM155A,),  
DISCRET_2D=_F (GROUP_MA=' FILETS',  
CARA=' K_T_D_L',  
VALE= (10000000.0, 10000000.0,),),);
```

*One can apply to the ordinary nets three behaviors, to see it [Table 5.2.2-1]:*

- 1) behavior of the first net (traction diagram);*
- 2) behavior of the second net (traction diagram);*
- 3) behavior of the current nets (traction diagram).*

*One can apply to the nets six particular behaviors, to see it [Table 5.2.2-1]:*

- 1) behavior of a truncated current net, (traction diagram), cf [§6.1] Remark 6.1-1;*
- 2) behavior of a truncated net of type A, (traction diagram);*
- 3) behavior of a truncated net of type B, (traction diagram);*
- 4) behavior of a current net whose play is except tolerance, (traction diagram);*
- 5) behavior of the first net whose play is except tolerance of the type A (traction diagram);*
- 6) behavior of the second net whose play is except tolerance of the type B (traction diagram).*

***The user will have to check in the data base, that the behaviors which it counts to use are well defined, cf [§6].***

*: 17/28*

The *FORCE\_NODALE* will be multiplied by the following function during calculation (order *STAT\_NON\_LINE*, key word *EXCIT*):

```
fonc=DEFI_FONCTION (NOM_PARA=' INST',
NOM_RESU=' TOUTRESU',
VALE= (0.0, 0.0, 5.0, 5000000.0,));
```

Order *DEFI\_LIST\_REEL* is used to define the list of moments necessary to incremental calculation (order *STAT\_NON\_LINE*, key word *COMP\_INCR*).

```
list=DEFI_LIST_REEL (DEBUT=0.0,
INTERVALLE= (_F (JUSQU_A=1.0,
NOMBRE=1,),
_F (JUSQU_A=2.0,
NOMBRE=1,),
_F (JUSQU_A=3.0,
NOMBRE=1,),
_F (JUSQU_A=4.0,
NOMBRE=1,),
_F (JUSQU_A=5.0,
NOMBRE=1,)),);
```

Two types of calculation can be selected:

.  
**ELASTOPLASTIC**, one uses the **behavior of the nets** given in the form of curve of traction in the base, one uses the incremental behavior then:

```
_F (RELATION=' DIS_GOUJ2E_PLAS',
DEFORMATION=' PETIT',
GROUP_MA=' FILETS',),),
```

.  
**RUBBER BAND**, that amounts plotting a straight line with the origin and the first point of the curve of traction **of the nets**, which makes it possible to make a linear elastic design, one uses it incremental behavior:

```
_F (RELATION=' DIS_GOUJ2E_ELAS',
DEFORMATION=' PETIT',
GROUP_MA=' FILETS',),),
```

In the example below we carry out an **ELASTOPLASTIC** calculation.

```
CALC=STAT_NON_LINE (MODELE=model,
```

*CHAM\_MATER=chmat,*  
*CARA\_ELEM=carael,*  
*EXCIT=\_F (CHARGE=charme,*  
*FONC\_MULT=fonc,*  
*TYPE\_CHARGE='FIXE\_CSTE'),*  
*COMP\_INCR= (\_F (RELATION='ELAS',*

### **The file of results**

*In this part one presents only the format COUNTS dedicated to the total calculation of an assembly pin-attach. In this last case the results are presented in two parts. The first gives correspondence number of net-number of node. The second part is organized in the form of a table having four columns. First relates to the increment or sequence number, second indicates the number of the nets, the third the reaction in **Newton** of the nets and the fourth cumulated reaction of the nets expressed in %. The format TABLE simply makes it possible to trace them*

*curves: reaction of the nets according to their number and cumulated reaction of the nets according to their number, using the software of layout of curves xmgrace.*

*One gives an outline of the format below COUNTS.*

## **6** **Presentation and use of the data base**

### **6.1 General**

*A threaded assembly leads to a modeling beam for the pin (element of beam) and 2D for the nets (discrete elements with two nodes) and attaches it (axisymmetric elements 2D). Three elements of an assembly are schematized on [Figure 6.1-a].*

*Ray interns support*

*High of Support*

*net 1*

*y*

*X*

*PIN*

*Body of Support*

*BR I D E*

*U (y)*

*v (y)*

*net N*

*Low of Support*

*NETS*

*External ray of the support*

*Appear 6.1-a: Schematized representation of an assembly*

*The pin and the support have a linear elastic behavior. The nonlinear behavior is located in the nets. It applies to the discrete elements and is given in an independent way by a local calculation axisymmetric 2D whose one exploited the results. This behavior appears under the form of a relation, indexed by the position of the net in the structure, between a difference of displacement  $U - v$  and force it shearing  $= Q = F (U - v)$  which is associated for him. Knowing it behavior of the elements constituting an assembly, one solves the total problem of which them displacements of the pin ( $U (y)$ ) and of support  $v (y)$  are solutions.*

*These are the various relations which are described, in the form of functions given point by point, in the base presented in this note. These curves were obtained for exerted tractions at the head pin and not of compressions.*

*Within the framework of the summary above, certain parameters characteristic of a given assembly intervene only during the integration of the total problem.*

*Instruction manual*

*U2.09 booklet: Tools and Solutions Trades*

*HT-66/05/004/A*

---

*Code\_Aster* ®

*Version*

*7.4*

*Titrate:*

*Realization of the calculation of an assembly pin-attaches*

*Date:*

*26/09/05*

*Author (S):*

*J. Key ANGLES*

*:*

*U2.09.02-C Page*

*: 21/28*

*It is the case, for example, of the number of nets, the total effort exerted at the head pin, conditions of blocking of the support (side surface and/or bases blocked (S)). These parameters do not appear*

*thus not in the specifications of a curve characteristic of a net.*

*The parameters which, on the other hand, determine the behavior of the nets are listed below:*

*.*

*Designation of the standardized form of the geometry of the pin, example: M33, M155;*

*.*

*Type of the assembly pin-attaches, example: NOMINAL or HELICOIL;*

*.*

*Stiffener top of support, example: WITH or WITHOUT;*

*.*

*Geometrical characteristics of play, example: MINIS or MAXIMUM;*

*.*

*Behavior of the nets and condition of contact pin/tapping, example: RUBBER BAND (linear rubber band) or ELASTOPLASTIC nonlinear traction diagram).*

*Each combination of these various parameters thus leads a priori to a specific relation shearing-jump of displacement. One locates each one of these combinations by a letter, by example: for the standardized form of the geometry of the M33 pin, if the assembly pin-attaches is NOMINAL, the stiffener top of support present (WITH), maximum clearance and the behavior of the nets*

*ELASTOPLASTIC one will speak about the M33 pin of alternative A, noted: M33\_A, cf [Table 6.2-3] Association forms standardized geometry of the pin (M33) and alternative (A) identifies in manner single the card of an assembly gathering the whole of the data relating to it (geometry of the assembly, characteristic of the assembly, curves behavior of the nets =  $Q = F(U - v)$ , definition of materials of the support and the pin) in the base, cf [Table 6.3-1] and [Table 6.3-2].*

#### **Remarks 6.1-1:**

*All configurations other than those with thread inserts (HELICOIL), cf [bib3], [bib4], were calculated in plasticity. If it is wanted nevertheless that the nets have a behavior linear rubber band it will be necessary to use RELATION=' DIS\_GOUJ2E\_ELAS' of key word COMP\_INCR order STAT\_NON\_LINE, cf [§ 5.2.3].*

*The curves representative of anomalies are they also specific place of the nets carriers of these anomalies, A and B respectively locating in the card of an assembly that of the first and second net.*

*The user will have to make sure that the types of behavior of the nets which it chose correspond or not to a configuration calculated in the base.*

## **6.2**

### **Presentation of the curves introduced into the data base**

*One presents, here version 1.0 of the data base at the date of the 16/09/1999.*

*The complete base can be obtained from EDF/BPI/UTO.*

*[Table 6.2-1] gathers the geometries available with their characteristics of assembly.*

#### ***Presentation of the data base***

***The data base is the subject of a specific data-processing treatment; certain rules are essential to observe in order to supplement it in a rigorous way.***

***The file of the base is divided into three parts: the references dates and version, the framework heading, them cards of the assemblies. These three parts are mentioned and detailed below:***

***1) The first line contains the date and the number of version of the base. This line is considered as being a comment.***

***2) The framework of the heading makes it possible to note the successive evolutions of the base: author (S), date version and object.***

***3) The third part contains the cards of the assemblies. Those are consisted of the manner following: the type of the pin as well as the alternative has.***

***B Geometry of the assembly, left in which one finds: the section of the pin, it ray external of the pin, the height or the step of the net and the interior ray of the support.***

***C The characteristics of the assembly, one finds there: the configuration net, the characteristic high of support, the type of play, the mechanical behavior, the material attaches and the material pin.***

***D Curves describing the behavior of the nets (FIRST NET, SECOND NET, NET RUNNING,...).***

***E Materials of the support and the pin: the Young modulus and the Poisson's ratio.***

***Note of use of calculation and postprocessing  
of a mechanical study according to the RCCM***

***Summary:***

***This document is a help with the use of postprocessing according to RCCM'S.***

***Chapter 1 described the postprocessing of tiredness according to the RCCM B3600, i.e. on an analysis of the type beam of pipings (TYPE\_RESU\_MECA=' TUYAUTERIE').***

***Chapters 2 and 3 refer to the postprocessing of tiredness according to the RCCM B3200, following a calculation 2D or massive 3D of a component or a particular zone. Chapter 2 relates to the analysis subjected to unspecified, mechanical transients or thermics in small number (TYPE\_RESU\_MECA=' EVOLUTION').***

***Chapter 3 relates to the analysis of a zone of piping subjected to many loadings, resulting from same situations as the lines of piping of chapter 1 (TYPE\_RESU\_MECA=' UNITAIRE').***

## ***Lawful analysis of a line of piping using POST\_RCCM option FATIGUE\_B3600***

***The goal of this chapter is to provide the indication to carry out of A to Z a calculation of a line of piping subjected to the whole of the loadings envisaged to its design, and its analysis lawful compared to the damage of tiredness according to the RCC-M B3600.***

***We will take for example line VVP studied in [bib1]. This one been the subject of test RCCM02 [V3.01.113] with regard to the analysis with tiredness according to RCC-M B3600. This order is described in the documentation of use [U4.83.11]. The detail of the equations and criteria is given in the reference material [R7.04.03].***

### ***1.1 Data available***

***For a line of piping given, one generally lays out:***

- telegraphic geometry of the line,***
- geometrical characteristics of the various sections of piping, and components  
(transitions from thicknesses, elbows, prickings, connections with large components),***
- loadings (mechanical and transients thermal) which must undergo the line during  
its operation,***
- materials composing the line (characteristics function of the temperature).***

***Example (drawn from test RCCM02 [V3.01.113]): data of modeling of line VVP:***

***The line comprises 10 elbows. It is directed since node NGV until node NBR***

***NGV  
NBR***

***Elementary characteristics:***

***Right parts:***

***•  
R= 406.4 mm, EP=32.mm***

**Pipe Steam Generator,  $R = 410.mm$ ,  $EP = 38.mm$ ;**

.

**Exit Br,  $R = 444.4mm$ ,  $EP = 70.mm$ ;**

**Elbows:**

.

**Group meshes corresponding to the elbows:  $R = 406.4mm$ ;  $EP = 34.mm$ ;**

.

**Coefficient of flexibility for all the elbows,  $c_{flex} = 6.032$ ;**

.

**Rays of bending of the elbows:  $1220mm$**

### ***Grids to be envisaged***

*Two types of grids must be made up:*

·  
*grid of the line, in telegraphic elements (meshs SEG2),*

·  
*a grid corresponding to each particular type of geometry for the transients thermics.*

*For example for the telegraphic grid, the elbows are discretized each one in 4 elements.*

*The meshs composing the elbow will be associated modeling POU\_C\_T. Right parts will be affected modeling POU\_D\_T.*

*Notice on the discretization: with regard to the static loadings, the discretization in elements POU\_D\_T does not need to be fine to provide precise solutions [R3.08.01]. By against for the dynamic analysis, to be able to obtain high clean modes with a precision sufficient, it is necessary to discretize more finely. For example, 4 elements per right part are generally sufficient for the first 10 Eigen frequencies.*

*With regard to the grids used for thermal calculations, it will be necessary to take care to net finely in the direction of the conduction of heat. For example, partly current of piping, the grid is a section of tube, modelled into axisymmetric. Only one element is enough in the direction axial. The 2 grids above correspond to the two thicknesses characteristic of the line.*

*For modeling, it is preferable (to obtain a correct solution) to use modelings*

with diagonalized thermal mass (AXIS\_DIAG, 3D\_DIAG).

## **1.3 Calculations mechanics**

### **1.3.1 Characteristics of materials**

**The elastic characteristics are to be provided according to the temperature (to take care to define a beach of sufficiently broad temperature to cover the whole of the thermal conditions seen by line. This is preferable with the definition of the prolongations which can lead to aberrations). One can use the catalogue material which gathers in particular the characteristics of all them materials of the RCCM.**

**For seismic calculations, it is necessary to add the density (integrating the weight of the water and of heat insulator). It is also necessary to introduce the characteristics of tiredness: coefficients  $N$  and  $m$  for calculation of  $K_e$ , and curve of Wöhler. It is preferable for the latter (being given its definition) to define an interpolation logarithmic curve).**

**E. GALENNE, J.M. PROIX, Mr. Key ABBAS**

**:**

**U2.09.03-B1 Page:**

**8/30**

**For example, the data material for line VVP are:**

**YOUNG=DEFI\_FONCTION (NOM\_PARA=' TEMP',  
VALE=(20.0, 20400000000.0, 50.0, 20300000000.0, 100.0, 20000000000.0,...),);**

**C\_ALPHA=DEFI\_FONCTION (NOM\_PARA=' TEMP',**

**VALE= (20.0, 1.092e-05,50.0, 1.114e-05,100.0, 1.15e-05,...,);**  
**NU=DEFI\_CONSTANTE (VALE=0.3);**

**# CURVED OF A48 TIREDNESS (one defines Nadm according to Salt)**

**WOHLER=DEFI\_FONCTION (NOM\_PARA=' SIGM',**

**VALE= (86000000.0, 1000000.0,**

**93000000.0,500000.0,**

**114000000.0,200000.0,**

**138000000.0,100000.0,**

**160000000.0,50000.0,**

**.....**

**INTERPOL=' LOG',);**

**RHOV = 8706.3;**

**MAT\_A48V=DEFI\_MATERIAU (ELAS\_FO=\_F (E=YOUNG, NU=NU,**

**RHO=RHOV,**

**TEMP\_DEF\_ALPHA=20.0,**

**ALPHA=C\_ALPHA,)**

**FATIGUE=\_F (WOHLER=WOHLER, E\_REFE=2.07E11,)**

**RCCM=\_F (SM=1.336E8,**

**N\_KE=0.2,**

**M\_KE=3.0,);**

### **1.3.2 Characteristics**

#### **elementary**

*They are entirely defined by AFFE\_CARA\_ELEM. With regard to the elbows, it is more practical in AFFE\_CARA\_ELEM to provide the orientations of the arcs using CENTER or POIN\_TANG. One can check (INFO=2) that radii of curvature recomputed by Aster correspond well to the rays of the elbows. It is necessary to define the coefficients of flexibility (definite for example in RCC-M B3600 [bib2]) correspondent with each elbow. For example:*

**CARA\_POU=AFFE\_CARA\_ELEM (MODELE=MODELE, INFO=2,**

**POUTRE= (\_F (GROUP\_MA=' TUYAU', SECTION=' CERCLE',**

**CARA= ("R", "EP"), VALE= (RTUB, EPTUB,)),**

**\_F (GROUP\_MA=' L1', SECTION=' CERCLE',**

**CARA= ("R", "EP"), VALE= (RGV, EPGV,)),**

**....**

**DEFI\_ARC= (\_F (GROUP\_MA=' C3', CENTRE= (10.62, - 4.9, 30.78,)), COEF\_FLEX=C\_FLEX,)**

**\_F (GROUP\_MA=' C7', CENTRE= (...**

**DISCRET= (\_F (GROUP\_MA=' RIG1', CARA=' K\_T\_D\_L', VALE= (0.0, 0.0, 0.0,)),**

**\_F (GROUP\_MA=' RIG2',....**

### ***1.3.3 Loadings and boundary conditions***

#### ***1.3.3.1 Boundary conditions common***

***In general there are boundary conditions common to all the loadings (for example one embedding corresponding to the passage of the line by a fixed point). For example:***

***BLOCBR=AFFE\_CHAR\_MECA (MODELE=MODELE,  
DDL\_IMPO= (\_F (GROUP\_NO=' NBR',  
DX=0.0,  
DY=0.0,  
DZ=0.0,  
DRX=0.0,  
DRY=0.0,  
DRZ=0.0),***

***E. GALENNE, J.M. PROIX, Mr. Key ABBAS***

***:***

***U2.09.03-B1 Page:***

***9/30***

#### ***1.3.3.2 Definitions of the loadings***

***The stabilized states defining the situations are in general the combination of loadings purely mechanical (actual weight, displacement imposed by a component in one or more points of the circuit) and thermal dilations (one does not consider the thermal transient here but only efforts due to the opposed dilation of the line for each state stabilized of each situation). This requires to define constant fields of temperature by zones or for all line, using CREA\_CHAMP. For example, the state stabilized number 5 is entirely defined by following loadings:***

```
CHAR1=AFFE_CHAR_MECA (MODELE=MODELE,
DDL_IMPO=_F (GROUP_NO=' NGV',
DX=0.046466,
DY=-0.0304945,
DZ=0.076,
DRX=0.0,
DRY=0.0,
DRZ=0.0),,);
```

```
TEMP286=CREA_CHAMP (TYPE_CHAM=' NOEU_TEMP_R',
OPERATION=' AFFE', MAILLAGE=MAILL,
AFFE=_F (TOUT=' OUI', NOM_CMP=' TEMP', VALE=286.0),,);
```

```
CHT286=AFFE_CHAR_MECA (MODELE=MODELE,
TEMP_CALCULEE=TEMP286,);
```

### *1.3.4 Calculations statics*

*A calculation (using MECA\_STATIQUE) is to be carried out for each stabilized state, by adding calculation efforts in option of calculation. Here for the loading number 5:*

```
RMECA5=MECA_STATIQUE (MODELE=MODELE, CHAM_MATER=CHAMPMAV,
CARA_ELEM=CARA_POU,
EXCIT= (_F (CHARGE=BLOCBR),
_F (CHARGE=CHT286,),
_F (CHARGE=CHAR1,)),,
OPTION=' EFGE_ELNO_DEPL',);
```

### *1.3.5 Calculations seismic*

*Seismic calculations are composed of inertial calculations, and static calculations of displacements anchorings. The latter are similar to static calculations previously described. One must carry out a calculation by component of displacement for each anchoring. For example, in the case of the line VVP, one needs a calculation for each component of displacement imposed on node NBR, and of even on node NGV:*

```
ANC_BRDX=AFFE_CHAR_MECA (MODELE=MODELE,
DDL_IMPO=_F (GROUP_NO=' NBR',
DX=4.0E-3, DY=0.0, DZ=0.0,
DRX=0.0, DRY=0.0, DRZ=0.0),,);
```

**RANCBRD**X=MECA\_STATIQUE (MODELE=MODELE, CHAM\_MATER=CHAMPMAV,  
CARA\_ELEM=CARA\_POU,  
EXCIT= (\_F (CHARGE=BLOCGV),,  
\_F (CHARGE=CHT20),,  
\_F (CHARGE=ANC\_BRDX),),  
OPTION=' EFGE\_ELNO\_DEPL');

*The calculation of the inertial answer requires several stages:*

### *1.3.5.1 Calculation*

#### *modal*

*That can be easily carried out using MACRO\_MATR\_ASSE and MODE\_ITER\_SIMULT. It is necessary to take care to take into account sufficient clean modes (here 11). Here modal calculation is carried out with the line full of water (modified densities) and the blocked DAB.*

**MACRO\_MATR\_ASSE** (MODELE=MODELE,  
CHAM\_MATER=CHAMPMAV,  
CARA\_ELEM=CARA\_DAB,  
CHARGE= (CHT287, BLOCGVBR),  
NUME\_DDL=CO ("NUME"),  
MATR\_ASSE= (\_F (MATRICE=CO ("RIGIDITY"), OPTION=' RIGI\_MECA'),,  
\_F (MATRICE=CO ("MASS"), OPTION=' MASS\_MECA'),,));

**TABL\_MAS=POST\_ELEM (MASS\_INER=\_F (TOUT=' OUI'), MODELE=MODELE, CHAM\_MATER=CHAMPMAV, CARA\_ELEM=CARA\_DAB,);**

**MODE\_MEC=MODE\_ITER\_SIMULT (MATR\_A=RIGIDITE, MATR\_B=MASSE, CALC\_FREQ=\_F (OPTION=' PLUS\_PETITE', NMAX\_FREQ=11),);**

**MODE\_MEC=CALC\_ELEM (reuse =MODE\_MEC, MODELE=MODELE, CHAM\_MATER=CHAMPMAV, CARA\_ELEM=CARA\_DAB, OPTION=' EFGE\_ELNO\_DEPL', RESULTAT=MODE\_MEC, EXCIT= (\_F (CHARGE=BLOCGVBR,)\_F (CHARGE= CHT287,)),);**

### **1.3.5.2 Answer inertial**

***It is necessary to define the spectra of accélérogrammes imposed on the supports. The horizontal spectrum is different vertical spectrum in the selected example: (attention with the units chosen for acceleration: here COMB\_SISM\_MODAL awaits accelerations in “G” cf key word SCALE of COMB\_SISM\_MODAL):***

**ACCE\_XY=DEFI\_FONCTION (NOM\_PARA=' FREQ', VALE= (1.0, 0.18, 2.2, 1.56, 3.0, 1.56,...), INTERPOL=' LOG', PROL\_DROITE=' CONSTANT', PROL\_GAUCHE=' CONSTANT',);**

**ACCE\_Z=DEFI\_FONCTION (NOM\_PARA=' FREQ', VALE= (1.0, 0.11, 2.0, 0.21, 3.0, 0.265,...), INTERPOL=' LOG', PROL\_DROITE=' CONSTANT', PROL\_GAUCHE=' CONSTANT',);**

## **1.4 Calculations**

### **thermics**

**The purpose of transitory thermal calculations are, in the case of the RCCM B3600, to evaluate the gradients**

**of maximum temperature during transients, in each part of the line. For the parts current to pipings, in theory, a thermal calculation of conduction 1D would be enough. In practice, one**

**will be able to carry out an axisymmetric calculation of a section of tube (the axial length with a grid not having**

**no importance). For the more complex zones, it can be necessary to carry out a grid 2D or precise 3D of the zone.**

**To reduce the command files, it can be useful to build each thermal modeling in a clean file, which will be included (order INCLUDE) in the principal command file**

*at the object time.*

### **1.4.1 Characteristics thermics**

*They can be extracted from the catalogue MATERIAL of Code\_Aster. They can be a function of temperature (in which case will have to be carried out a nonlinear thermal calculation), or interpolated with*

*average temperature of each transient to be calculated (practical current, but to validate in all rigour). For example, for each of the 2 transients of line VVP:*

**# COEFS AVERAGE OF COEF A 273.5**

**MATHER=DEFI\_MATERIAU (THER=\_F (LAMBDA=46.595, RHO\_CP=4.25E6,,));**

**CHMAT=AFFE\_MATERIAU (MAILLAGE=MA,  
AFFE=\_F (TOUT=' OUI', MATER=MATHER,,));**

**# COEFS AVERAGE OF COEF A 281**

**MATHER2=DEFI\_MATERIAU (THER=\_F (LAMBDA=46.37, RHO\_CP=4.27E6,,));**

**CHMAT2=AFFE\_MATERIAU (MAILLAGE=MA,  
AFFE=\_F (TOUT=' OUI', MATER=MATHER2,,));**

### **1.4.2 Calculations of the transients**

*They are often characterized by a history of temperature in internal skin of piping (fluid temperature) and a coefficient of exchange. It will have to be taken care that the temporal discretization*

*that is to say sufficiently fine for good “to collect” the variations in temperature (to carry out several tests).*

**COEFH=DEFI\_CONSTANTE (VALE=3.E4,);**

**TR2=DEFI\_FONCTION (NOM\_PARA=' INST', VALE= (0.0, 274. , 10.0, 274. , 310.0, 272....),);**

**CHTH2=AFFE\_CHAR\_THER\_F (MODELE=MOTHER,  
ECHANGE=\_F (GROUP\_MA= (“ECHAND”, “ECHANC”),,  
COEF\_H=COEFH, TEMP\_EXT=TR2,,));**

**LISTH2=DEFI\_LIST\_REEL (DEBUT=0.0,  
INTERVALLE= (\_F (JUSQU\_A=10.0, PAS=10.0),  
\_F (JUSQU\_A=310.0, PAS=10.0), \_...),);**

**TEMP2=THER\_LINEAIRE (SOLVEUR=\_F (RENUM=' MDA'), MODELE=MOTHER,  
CHAM\_MATER=CHMAT, EXCIT=\_F (CHARGE=CHTH2,));**

**INCREMENT=\_F (LIST\_INST=LISTH2,)  
TEMP\_INIT=\_F (VALE=274.5,));**

**:**

**U2.09.03-B1 Page:**

**12/30**

### **1.4.3 Extraction of the results**

**For the analysis with POST\_RCCM, it is necessary to extract the values and the average temperatures, for every moment calculated, on a segment defined by INTE\_MAIL\_2D (or a group of nodes, reorientated using DEFI\_GROUP, OPTION = 'SEGM\_DROI\_ORDO') energy of the skin interns towards external skin. For example:**

**TABTH2D=POST\_RELEVE\_T (ACTION=\_F (INTITULE='temp2', GROUP\_NO='BASD', RESULTAT=TEMP2, NOM\_CHAM='TEMP', NOM\_CMP='TEMP', OPERATION='EXTRACTION',));**

**TABMO2D=POST\_RELEVE\_T (ACTION=\_F (INTITULE='temp2', GROUP\_NO='BASD', RESULTAT=TEMP2, NOM\_CHAM='TEMP', NOM\_CMP='TEMP', OPERATION='MOYENNE',));**

### **1.5**

**Post treatment following the RCCM**

**It any more but does not remain to call POST\_RCCM with the B3600 option, while providing [U4.83.11]:**

- 
- geometry of the line of piping,*
- 
- the material field: it is the chart of materials assigned to the groups of meshes of grid by AFFE\_MATERIAU for which it is necessary to add the curve of tiredness, E\_REFE, m and N (key words RCCM),*
- 
- AFFE\_CARA\_ELEM makes it possible to affect the elementary characteristics,*
- 
- indices of constraints (in each node of the grid),*
- 
- the scenario of operation containing the list of the situations:*
  - *for each situation:*
  - *numbers of occurrences of each situation (thus of each stabilized state),*
  - *pressure and average temperature of each stabilized state,*
  - *list of the mechanical loadings (characterized by a number) of each state stabilized,*
  - *the group of membership of the situation,*
  - *the associated thermal transient,*
- 
- results of calculations for each mechanical loading (including the seism), (located by its number, with for information the name of the loading case): field by elements with the nodes generalized efforts, for each loading (EFGE\_ELNO\_DEPL, or SIEF\_ELNO\_ELGA),*
- 
- for each node, a reference to a definite thermal result below,*
- 
- results of thermal calculations: calculations EF 2D or 3D which give these infos depend at the same time on the geometry and transient. There is thus a thermal calculation by type of junction, and by type of transient.*

*To complete the example of line VVP, the call to POST\_RCCM is as follows (INFO=2 allows to obtain details of calculations):*

```
TBRCCM1=POST_RCCM (OPTION=' FATIGUE_B3600', INFO=2,  
CHAM_MATER=CHAMPMAV, MODELE=MODELE, CARA_ELEM=CARA_POU,  
# zone of analysis  
ZONE_ANALYSE=_F (MESH = ("M1", "m2")),  
# results mechanical (calculated with MECA_STATIQUE)  
RESU_MECA= (  
_F (NUME_CHAR=1,  
NOM_CHAR=' STATE 1 SITUATION 1 ',  
TOUT_ORDRE=' OUI', RESULTAT=RMECA1,
```

*NOM\_CHAM=' EFGE\_ELNO\_DEPL',),*

*\_F (NUME\_CHAR=2,  
NOM\_CHAR=' STATE 2 SITUATION 1 ',  
TOUT\_ORDRE=' OUI', RESULTAT=RMECA2\_9,  
NOM\_CHAM=' EFGE\_ELNO\_DEPL',),*

**Complete detailed calculation of an unspecified component and analyze lawful B3200 using POST\_RCCM**

**This type of analysis is justified when one wants to analyze a component subjected to one or with little of transients (and not of seism), in order to check the various criteria of the RCC-M B3200 (deformation excessive, progressive deformation, tiredness according to appendix ZH210).**

**If one wishes to analyze a component with tiredness, for the whole of the situations to which it will be subjected, and in particular with the seism, it is preferable to use the method described in the following chapter.**

**This type of analysis functions only for modelings of continuous mediums 2D (D\_PLAN, C\_PLAN, AXIS) or 3D.**

**One will take for example tests RCCM01, and SSLV100.**

**2.1**

**Calculation of the component**

**It is a question here of carrying out the direct calculation of the component, for the loadings which one wants to evaluate criteria.**

**To model the elbows or prickings, it is convenient to use tools ASCOUF (macros orders MACR\_ASCOUF\_MAIL and MACR\_ASCOUF\_CALC) and ASPIC (MACR\_ASPIC\_MAIL and MACR\_ASPIC\_CALC).**

**With the exit of these calculations, one lays out of a certain number of concepts results, thermoelastic 2D or 3D, produced by MECA\_STATIQUE or STAT\_NON\_LINE, and for which one calculated the option SIGM\_ELNO\_DEPL (by taking care in CALC\_ELEM to provide the load containing them temperatures) or better: SIEF\_ELNO\_ELGA (CALC\_ELEM).**

***For example (RCCM01):***

```
RESU2=MECA_STATIQUE (MODELE=MO, CHAM_MATER=CHMAT,  
LIST_INST=LINST,  
EXCIT= (_F (LOAD = CHTHER),  
_F (LOAD = CHMEC, FONC_MULT = FCTMUL)),  
OPTION= ("SIGM_ELNO_DEPL",  
)
```

**2.2**

***Definition of the segments and extraction of the constraints***

***It is a question of extracting, on each segment studied, the constraints, for each transient. Let us recall***

***that the criteria of the RCC-M B3200 are to be checked for the whole of the possible segments, crossing the component of the skin interns to the external skin. The choice of the maximizing segment the criteria is the responsibility of the user. For a complex geometry, this one will have to thus calculate a certain number of segments.***

***In practice, in Code\_Aster, several methods are possible to define the segments of analysis then to extract the constraints there:***

***the first consists in using orders INTE\_MAIL\_2D or INTE\_MAIL\_3D, according to geometrical dimension of the problem, to define an unspecified segment passing in through grid then to extract the constraints by POST\_RELEVE\_T:***

```
LIGNE1=INTE_MAIL_2D (MAILLAGE=MA,  
DEFI_SEGMENT=_F (ORIGIN = (-1.0, 0.5),  
END = (1.0, 0.5)),  
INFO=2)
```

:

**U2.09.03-B1 Page:**

**16/30**

**TAB2=POST\_RELEVE\_T (ACTION=\_F (ENTITLES = "LINE",  
WAY = LIGNE1,  
RESULT = RESU2,  
NOM\_CHAM = "SIGM\_ELNO\_DEPL",  
OPERATION = "EXTRACTION",  
TOUT\_CMP = "YES"),),)**

*the second method consists in using a preexistent group of nodes in the grid, defining a segment. This method obligatorily requires to reorder as a preliminary the group of nodes, so that the nodes the component are arranged skin interns towards external skin:*

**MA=DEFI\_GROUP (reuse=MA, MAILLAGE=MA,  
CREA\_GROUP\_NO= (\_F (OPTION = "SEGM\_DROI\_ORDO",  
NAME = "LINE",  
GROUP\_NO=' GNI',  
NOEUD\_ORIG = "N22",  
NOEUD\_EXTR = "N12",  
PRECISION = 1.E-03,  
CRITERION = "RELATIVE"))**

**TAB2=POST\_RELEVE\_T (ACTION=\_F (ENTITLES = "LINE",  
GROUP\_NO = LINE,  
RESULT = RESU2,  
NOM\_CHAM = "SIGM\_ELNO\_DEPL",  
OPERATION = "EXTRACTION",  
TOUT\_CMP = "YES"),),)**

*the last method consists in using macro-order MACR\_LIGN\_COUPE to define the segment of analysis starting from its ends and to extract the constraints:*

**MACR\_LIGN\_COUPE (RESULTAT=RESU2,  
NOM\_CHAM=' SIGM\_ELNO\_DEPL',  
MODELE=MO,  
LIGN\_COUPE=\_F (NB\_POINTS=5,**

***COOR\_ORIG= (-1.0, 0.5),  
COOR\_EXTR= (1.0, 0.5),  
TABLE=CO ("TAB2"),),)***

## **2.3**

### ***Calculation of the various criteria using POST\_RCCM***

***The criteria available are:***

- .  
criteria of level 0 by option PM\_PB,***
- .  
criteria of level A (except tiredness) by the option SN,***
- .  
criteria of tiredness (also of level A) by option FATIGUE\_ZH210.***

#### **2.3.1 Option PM\_PB**

***Option allowing to calculate the criteria of level 0 which aim at securing the material against damage of excessive deformation, plastic instability and elastic and elastoplastic instability.***

***These criteria require the calculation of the equivalent constraints of membrane  $m$   
 $P$ , of membrane***

***local  $L$***

***$P$ , of inflection  $B$***

***$P$  and of membrane plus inflection  $m$***

***$P + B$***

***$P$ . The points of calculation are both ends of the segment of analysis. If several segments of extraction were used to define one even table of constraints, calculation is done successively for each one of them.***

*The values limit are  $S_m$  and  $1.5 S_m$ ,  $S_m$  being working stress function of material and of the temperature, given by the key word  $SM$  of key word  $RCCM$  in  $DEFI\_MATERIAU$  [U4.43.01].*

**Note:**

*The calculation of  $PM$  and  $PMPB$  is only done starting from the primary constraints, therefore out constraints of thermal origin. If  $TABL\_SIGM\_THER$  is indicated, it is supposed that it result indicated in  $TABL\_RESU\_MECA$  corresponds to a thermomechanical calculation and one him thus withdrawn the thermal stresses. If only  $TABL\_RESU\_MECA$  is indicated, calculation is done directly starting from the constraints indicated in the table.*

### 2.3.2 Option

#### SN

Option allowing to calculate the criteria of level A (except tiredness) which aim at securing the material against the damage of progressive deformation. They require the calculation of the amplitude of variation

of constraint linearized in a point, noted  $S_n$ .

If the user asks it (presence of operand `TABL_SIGM_THER`) one also the calculation carries out of  $S^*$

$N$ . The points of calculation are the two ends of the segment of analysis. If several segments of extraction were used to define the same table of constraints, calculation is done successively for each one of them.

In each point end of this segment length  $L$ , one calculates:

$$S_n = \max_{ij} \left( \frac{\sigma_{ij}(T1) - \sigma_{ij}(T2)}{L} \right)$$

### **2.4.3 Option**

#### **TIRE**

*Calculation with the option TIRES is done in the following way:*

```
FAT1=POST_RCCM (MATER=MAT,  
TYPE_RESU=' VALE_MAX',  
OPTION=' FATIGUE',  
TITRE=' FATIGUE_ZH210, RESULT: RESU2+RESUTH',  
TRANSITOIRE= (_F (TABL_RESU_MECA = TAB1,  
INST = (0. , 1. , 2. ), NB_OCCUR = 200),  
_F (TABL_RESU_MECA = TABTH,  
INST = (0. , 1. , 2. ), NB_OCCUR = 200),  
)
```

*The table produced in the case TYPE\_RESU = “DETAILS” gives, for each combination of moments (of occurrences NB\_OCCUR\_1 and NB\_OCCUR\_2) and for each end: SN, SN\*, SP, KE, SALT, NADM and DAMAGE (= min (NB\_OCCUR\_1, NB\_OCCUR\_2) /NADM). Value DOMMAGE\_CUMU, indicated at the end of the table for each end of the segment, corresponds to the combination of the damage of all under-cycles.*

*The table produced in the case TYPE\_RESU = “VALE\_MAX” gives only the maximum value of each the parameters listed above and corresponding moment. It should be noted that the number of acceptable cycles posted is the maximum of this parameter on the whole of the combinations, and it thus does not correspond to the SALT and the maximum DAMAGE indicated on the same line. SN values and SN\* indicated are the same ones as those which would come from a calculation with the option “SN”.*

### **3 lawful Study of a particular zone of one component subjected to many loadings**

*This chapter relates to the analysis with the tiredness of a component, or a particular zone of one component pertaining to a line of piping, modelled in a detailed way in 2D or 3D, and subjected to the same situations as the lines of pipings of the first chapter. That means that it will be necessary to know the constraints on one or more segments, for each loading, with in private individual the seism, and each thermal transient.*

*The management of many results being expensive, it is of use in this case to carry out calculations mechanics for unit loadings (a loading by direction, of standard 1) then to carry out linear combinations to obtain the response in each state stability of each situation. This process in the case of reduces the mechanical number of calculations with 7 a component to two ends (elbow, transition from thickness...) : 6 unit loadings and 1 unit pressure.*

#### **3.1**

#### **Definition of the zone of analysis**

*The zone to be analyzed must be selected such as the limits of the models correspond to points where torques of efforts applied are known. Right parts of the zone with a grid, assimilable to grids 3D of pipes, must be sufficiently long, so that the mechanical solution with ends is close to a solution of the beam type: displacements and constraints varying linearly in the thickness. In this case, one will be able to apply at the ends the 6 components of a torque unit, via a connection 3D-beam (key word LIAISON\_ELEM of AFFE\_CHAR\_MECA), with an element of beam, or even with a discrete element having of the degrees of freedom of translation and of rotation.*

*Guard should well be taken to define the geometry 3D in a reference mark coinciding with the local reference mark of the zone analyzed during the calculation of the efforts of beam, so that the torques are defined in the same one locate. In the contrary case, the user will have to carry out a change of reference mark of the torques.*

*In the case of an elbow, whose inflection generates an ovalization, one will be able to benefit from the connection 3D PIPE, which makes it possible to connect the end 3D of the grid to pipe sections, which have degrees of freedom of ovalization. This makes it possible to decrease the length of the right parts with a grid in 3D.*

*Let us take the example of test RCCM04 [V3.04.136] resulting from the study [bib1]: it is about the detailed study of a longitudinal under-thickness in an elbow line VVP studied in chapter 1. This elbow is*

with a grid using ASCOUF.

## 3.2

### ***Preliminary calculation of the efforts in extreme cases of the zone of analysis***

*Efforts applied to the limits of the model, corresponding to each loading of the list of situations, will have to be calculated as a preliminary by an analysis of the beam type, as in chapter 1. One then obtains the values of the components of the torques applied to the limits of the model 3D, for each stabilized state of each situation. (The list of the situations is that given to chapter 1). For the elbow studied in [bib1], that gives for example:*

### **3.3**

#### ***Characteristics of materials***

*The definition of materials is identical to that of chapter 1, excluded the density, useless here. The thermal characteristics are similar. One will be able to use the catalogue material for to profit from the characteristics of the RCC-M according to the temperature.*

#### ***Notice concerning the values to use:***

*The RCC-M B3200 specifies that in the case of combination of mechanical loadings and thermics, which is the case general, it is necessary to take  $S_m$  at the maximum temperature of each transient. On the other hand the use in B3600 is to choose  $S_m$  at the average temperature of studied transients.*

*It is essential to check the relevance of the system of units. Let us note for example that the use of MACR\_ASCOUF\_MAIL implies to use the mm as unit of length. Therefore, all constraints will be in MPa ( $N/mm^2$ ). In the same way, it is necessary to take guard with the units used in the characteristics thermics.*

### 3.4

#### ***Elementary characteristics of the discrete or linear elements***

*Characteristics of the possible elements of beam, used to apply the torques of efforts, must correspond to that of piping in the studied zone, and with the grid 3D. In definition of the section, R indicates the external ray of the section. The example of two here is given connections: embedded side, one applies a connection with a discrete element. Other side, one apply torques, the connection is of the 3D-beam type:*

```
MOD=AFFE_MODELE (MAILLAGE=MA,
AFFE= (
_F (GROUP_MA=' 3D', MODELING = "3D", PHENOMENON = "MECHANICAL"),
_F (GROUP_MA= ("AB",), MODELING = "POU_D_T", PHENOMENON = "MECHANICAL"),
_F (GROUP_NO = "It, MODELING = "DIS_TR", PHENOMENON = "MECHANICAL"))
)
CELEM=AFFE_CARA_ELEM (MODELE=MOD,
POUTRE=_F (GROUP_MA = ("AB",), SECTION = "CIRCLE",
CARA = ("R", "EP",), VALE = (0.8128, 0.032)),
DISCRET=_F (GROUP_NO = "It,
CARA = "K_TR_D_N", VALE = (0. , 0. , 0. , 0. , 0. , 0. ,)))
```

*It is necessary to give the characteristics of stiffness to the discrete element, for reasons data processing.*

### 3.5

#### ***Boundary conditions for the calculation of the unit loadings***

*It is thus necessary to apply to the limits of the model each component of the torque applied by the line of piping in this point. In practice, one embeds an end (via a connection 3D-beam or 3D-pipe, which avoids the stress concentrations), and one apply the torques to each other end (either 6 components in the case of an elbow or of a right part, and 12 components in the case of a pricking).*

```
CL=AFFE_CHAR_MECA (MODELE=MOD, LIAISON_ELEM= (
# Connection 3D-DISCRET
_F (OPTION = "3D_POU",
GROUP_MA_1 = "KNOWN",
GROUP_NO_2 = "It),
# Connection 3d-BEAM
```

```
_F (OPTION = "3D_POU",  
GROUP_MA_1 = "SF",  
GROUP_NO_2 = "A"),  
# Embedding of the specific discrete element  
DDL_IMPO=_F (GROUP_NO = "It, DX = 0. , DY = 0. , DZ = 0. , DRX = 0. ,  
DRY = 0. , DRZ = 0.),  
)  
# a component of the torque:  
FX=AFFE_CHAR_MECA (MODELE=MOD,  
FORCE_NODALE=_F (GROUP_NO = "B", FX = 1000.))  
  
MX=AFFE_CHAR_MECA (MODELE=MOD,  
FORCE_NODALE=_F (GROUP_NO = "B", MX = 1.))
```

**Note:**

*The "unit" value of the loadings depends on the unit of the torques which will be provided to POST\_RCCM. Here, the efforts are in kN and the moments in N.m. the pressures are in bars. In the example presented here, one applies a unit effort of 1kN, one unit moment of 1N.m and a unit pressure of 1bar (either 1E5 Pa).*

*Instruction manual*

*Author (S):*

*E. GALENNE, J.M. PROIX, Mr. Key ABBAS*

*:*

*U2.09.03-B1 Page:*

*24/30*

*For the loading of pressure, it is necessary to apply to the surface meshes intern a pressure unit, without forgetting the basic effect (which can be defined as follows, or directly using key word EFFE\_FOND):*

```

REXT= 0.8128
EPTUB= 0.032
PINT= 1.E5
RINT= REXT-EPTUB
SINT= PI* (RINT*RINT)
FTOT= PI* (RINT*RINT)
SEXT= PI* (REXT*REXT)
SFON= SEXT-SINT
FREP= FTOT/SFON
PRES1=AFFE_CHAR_MECA (MODELE=MODMECA,
PRES_REP=_F (GROUP_MA=' SURFINT',
PRES=PINT),
FORCE_FACE=_F (GROUP_MA=' EFOND',
FX=FREP,));

```

**Note:**

*It is always preferable to direct the meshes of face where the pressures are applied, because they are not always directed suitably by the mailleurs. This is done simply using operator MODI\_MAILLAGE:*

```

MAIL=MODI_MAILLAGE (reuse =MAIL, MAILLAGE=MAIL,
ORIE_PEAU_3D= (_F (GROUP_MA=' SURFINT',),
_F (GROUP_MA=' EFOND',)),
MODELE=MODMECA,);

```

**3.6 Calculations****statics**

*7 static calculations will be carried out: one by unit component of torque, and for the pressure. seism does not intervene on this level, because it is translated in fact by torques, whose components have unknown signs. It is POST\_RCCM which will carry out all the combinations of sign.*

**3.7****Statements of the constraints**

*After having determined a certain number of segments on which the criteria will be evaluated, it remains to extract the values from constraints (SIEF\_ELNO\_ELGA or SIGM\_ELNO\_DEPL) for each loading, on each segment. Let us recall that the criteria of the RCC-M B3200 are to be checked for the whole of the possible segments, crossing the component of the skin interns to the skin external. The choice of the segment maximizing the criteria is the responsibility of the user. For one complex geometry, this one will have to thus calculate a certain number of segments.*

*In practice, in Code\_Aster, three methods of definition of the segments are possible:*

.  
*the first consists in using orders INTE\_MAIL\_2D or INTE\_MAIL\_3D, according to geometrical dimension of the problem, to define an unspecified segment passing in through grid:*

```
LIGNE1=INTE_MAIL_2D (MAILLAGE=MA,  
DEFI_SEGMENT=_F (ORIGIN = (-1.0, 0.5,)),  
END = (1.0, 0.5,)),  
INFO=2)
```

*Instruction manual*

*U2.09 booklet: Tools and Solutions Trades*

*HT-62/06/004/A*

---

**Code\_Aster** ®

*Version*

8.2

*Titrate:*

*Note of use of calculation and postprocessing RCCM*

*Date:*

22/02/06

*Author (S):*

**E. GALENNE, J.M. PROIX, Mr. Key ABBAS**

:

*U2.09.03-B1 Page:*

25/30

.  
*the second consists in using a preexistent group of nodes in the grid, defining a segment. This method obligatorily requires to reorder the group as a preliminary nodes, so that the nodes the component are arranged internal skin towards the skin external:*

```
MA=DEFI_GROUP (reuse=MA, MAILLAGE=MA,  
CREA_GROUP_NO= (_F (OPTION = "SEGM_DROI_ORDO",  
NAME = "LINE",  
GROUP_NO=' GNI',  
NOEUD_ORIG = "N22",  
NOEUD_EXTR = "N12",  
PRECISION = 1.E-03,  
CRITERION = "RELATIVE"))
```

the third consists in using *MACR\_LIGN\_COUPE*, which carries out a projection of the fields constraints realised with the nodes on a grid 1D whose one provides the ends and it a number of elements:

```
MACR_LIGN_COUPE (RESULT = RESUT, NOM_CHAM=' SIGM_NOEU_DEPL',
MODEL = MODMECA,
LIGN_COUPE = (_F (NB_POINTS = 10,
COOR_ORIG = (0,3,0.18),
COOR_EXTR = (0,3,0.2),
COUNT = CO ("TAB2")),))
```

To reduce calculations, the tables results of these extractions could be written on a file with assistance of *IMPR\_TABLE*, with the format *ASTER*. Thus postprocessing will not have any more but to read again these tables (with assistance of *LIRE\_TABLE* [U7.02.03]) without having to manage results of big sizes.

The tables have the following form:

```

### **3.8 Calculations** ***thermomechanical***

***Thermal calculations must be carried out for each thermal transient to take in count. Guard should be taken to be netted finely, for example with the assistance the linear elements with mass diagonalized (modeling 3D\_DIAG), which makes it possible to avoid the goings beyond of maximum. Steps times must be optimized, to collect the variations in temperature in the thickness due to thermal transients violent one.***

***If one wants to model transients of great amplitude, it is more precise to carry out calculations nonlinear thermics (THER\_NON\_LINE) by considering the variable thermal characteristics with the temperature.***

***26/30***

***Generally, the thermal loadings consist of stories of temperatures fluid in skin intern, with coefficients of exchange constant, or function of time. They are often used expression following to estimate the coefficients of exchange according to the flow of the fluid (formula of Colburn):***

*F*  
*0.8*  
*.*  
*4*  
*.*  
*0*  
*4Q*  
*H = 0.023*

*.*  
*0*  
*Re Pr with Re =*  
*where Q is the flow of the fluid, D the diameter interns*

*D*  
*D<sup>2</sup> v*  
*F*  
*F*

*pipng, the thermal conductivity of water, v kinematic viscosity and Pr the number of*

*F*  
*Prandtl. All these characteristics vary in fact according to the temperature. One can choose*  
*average temperature of each transient to evaluate these quantities.*  
*That can be introduced directly into the command file in the form:*

*PRANDTL= 1.35*  
*LF= 0.45*  
*NF= 0.123E-6*  
*DF= 0.1319*  
*DEBIT=20/3600*  
*RE1= 4\*DEBIT/NF/PI/DF/DF*  
*COEFH= 0.0023\* (PRANDTL \*\* (0.4))\* (RE1 \*\* (0.8))\*LF/DF*

*The others faces (external face and ends) are often isolated, which results in a condition*  
*null flow (not of condition particular to introduce for thermal calculation). The coefficient of*  
*Prandtl is adimensional, thermal conductivity is in W/m.°C, the flow in m<sup>3</sup>/s and viscosity*  
*kinematics in m<sup>2</sup>/s.*

*The thermal results resulting from preceding calculations are introduced like loadings for*  
*thermomechanical calculations. One will use preferably meshes of order 2. Fields of*  
*P1 temperature will thus be projected on this P2 grid, using PROJ\_CHAMP.*

*TEMP2 = PROJ\_CHAMP (*  
*METHODE=' ELEM',*  
*RESULTAT=TEMP,*  
*MODELE\_1=MODTHER,*

*MODELE\_2=MODMECA,  
TOUT\_ORDRE=' OUI')*

*With MODTHER the thermal model (3D\_DIAG, elements of order 1) and MODMECA the mechanical model (3D, elements of order 2). One can arrive at the same quality of results (without using 3D\_DIAG) with a single grid, of order 2, sufficiently end to be able to use steps of fine times.*

*The boundary conditions associated must make it possible to avoid the movements of solid body (embedding of the one of the ends via the discrete element for example).*

*Once thermomechanical calculation carried out, one **extracts the constraints** by one from the three methods already quoted. One will then obtain, for each segment, and each transient, a table containing the 6 components of constraints, for each moment (the list of moments can be reduced to the moment of the extraction).*

### **3.9**

#### ***POST\_RCCM on each segment***

*On each segment, it is necessary to call POST\_RCCM, option PM\_PB, SN or TIREDNESS. Analysis more complete corresponds to the option TIRES.*

*The material east supposes single along the segment. One must thus provide to POST\_RCCM material (defined by DEFI\_MATERIAU or INCLUDE\_MATERIAU) containing the mechanical characteristics with maximum temperature of the transients.*

*Instruction manual*

### ***3.10 Description of the produced tables***

*The table produced for option PM\_PB contains the values of PM, PB and PM-PB at the ends of segment for each situation of loading. The value indicated corresponds to the maximum of parameter considered, calculated with the mechanical states A and B defined by the user. If the group of situations includes/understands a loading of the type SEISM, the value indicated for a situation (out seism) of this group corresponds to the maximum obtained by taking of account the loadings not signed seism. The value without seism of this situation can be found in the file message if INFO=2.*

*The table produced for the option SN contains values SN and SN\* at the ends of the segment for each situation of loading. If the group of situations includes/understands a loading of the SEISM type, the value indicated for a situation (except seism) of this group corresponds to the maximum obtained in taking into account the not signed loadings of the seism. The value without seism of this situation can be found in the file message if INFO=2.*

*The table produced for the option TIREDNESS shows same information as for the options the preceding ones (PM, PB, PM-PB, SN and SN\*) for each situation, and the value of the factor of use*

*FACT\_USAGE and its contribution %\_FACT\_USAGE for each combination of possible situation. Lastly, for the two ends of the segment, one finds SN\_MAX, SP\_MAX, SALT\_MAX and FACT\_USAGE\_CUMU:*

*ASTER 6.03.18 CONCEPT TBRCCM1 CALCULATES THE 01/10/2002 A 10:51: 56 OF TYPE TABL\_POST\_RCCM*

*PLACE SM SN/3SM SN\_MAX SP\_MAX SALT\_MAX FACT\_USAGE\_CUMU  
ORIG 1.33600E+08 3.48221E-02 1.39567E+07 1.43295E+07 7.27012E+06 1.39288E-05  
EXTR 1.33600E+08 5.23888E-02 2.09974E+07 2.19719E+07 1.11475E+07 3.76647E-05*

*It is possible to obtain the detail of calculations with INFO=2: the values of SN and SP are then indicated in the file message for each combination of loading of each group. matrices SALT are also indicated to each iteration of the calculation of the cumulated damage.*

## **1 Methods**

**of use**

### **1.1**

#### **Description of the Zmat library**

**Within the framework of partnership EDF (MMC-AMA-LAMSID) - School of the Mines (Center of Materials), it**

**coupling between Zmat, which is the module of definition of the behaviors of the Zebulon code, and Code\_Aster was carried out. Zmat contains a module of integration of laws of behavior and one library of behaviors including/understanding élasto-visco-plasticity, the damage, the models multi-scale...**

**Moreover, the user can define his own behavior, by describing the equations governing it behavior using a high-level language (Zebfront), integration being then realized by Zmat.**

### **1.2**

#### **Licence and right of access**

**The use of Zmat for Code\_Aster is envisaged, within the framework of the partnership School of the Mines - EDF,**

**for calculations of R & D only, which excludes in particular studies IPS. Extension of these conditions of use starting from the introduction of version 8 (at the end of 2006) is being studied.**

*Out of this framework, the licence of Zmat can be acquired near the Center of Materials of the ENSMP.*

*For as much Zmat is not pre-necessary of Code\_Aster, one can build and use Code\_Aster with or without the Zmat library.*

*Corrective and evolutionary maintenance (in particular compared to the evolution of the systems of exploitation, and compilers) of the Zmat library concerns the ENSMP. Routines of interface are maintained by the team of development of Code\_Aster.*

### **1.3**

#### ***Machines usable at EDF R & D***

*Zmat is physically installed on the waiter of centralized development of Code\_Aster (Alphaserveur), like on departmental Linux waiters (clp50a8 with AMA, ret20fi with MMC). However the access to the centralized machine is necessary for the access to the licence of use.*

### **1.4 Documentation**

*The documentation of Zmat is available in the form of files to format pdf, in the repertory of installation of Zmat, in general [ASTER\_ROOT] /public/Z8.3/HANDBOOK where [ASTER\_ROOT] is the principal repertory of the installation of Code\_Aster, and is worth /opt/aster in general or .*

*On the waiter Aster, the documentation of Zmat is in the repertory /aster/local/Z8.3/HANDBOOK.*

*The documents relating to Zmat are z\_mat\_manual.pdf and devel\_manual.pdf.*

### **1.5**

#### ***Limitations and prospects***

*The interface (and Zmat modulates it) does not expect that one variable of order (scalar): the temperature.*

*To define a material dependent on another variable of order (fluence, corrosion, drying...) the interface should be modified.*

*The behaviors, in version 8.1, are accessible only in small deformations (key word DEFORMATION=' PETIT' or "PETIT\_REAC").*

*Instruction manual*

*U2.10 booklet: External couplings*

*HT-62/06/004/A*

**Code\_Aster** ®

**Titrate:**

**Note of use of the Code\_Aster-Zmat coupling**

**Date:**

**15/02/06**

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U2.10.01-B Page**

**: 4/8**

**Notice on the performances**

**The integration of the behavior by using the Zmat library takes 2 to 3 times more time that the integration of the model equivalent included to Code\_Aster.**

**Precaution for use**

**The user defines certainly his behavior and the values of the coefficients material in Zmat file, but it must also define an elastic material (E and) if it wants to use the matrix rubber band or the elastic prediction. Guard should then be taken required values coherent with those of the Zmat files. In the same way, for the orders of postprocessing (CALC\_ELEM, CALC\_NO, POST\_ELEM), certain options use the elastic coefficients: in this case, even notices that previously.**

**As currently realized, the Code\_Aster-Zmat interface does not make it possible to establish a bond between materials managed by Zmat and those managed by Code\_Aster (in particular the catalogue material).**

**If the need is felt some, a stronger bond with DEFI\_MATERIAU would be to envisage, so that the users can give the characteristics material in the formalism Aster, them to store in the catalogue material, by generating the corresponding Zmat data.**

**2**

**To use a behavior of the library of Zmat**

**2.1**

**Contents of card-indexing Zmat**

*To card-index Zmat at the same time allows to define the behavior to provide the values of the parameters (constant or variable with the temperature) for this behavior. The syntax of this file is described in the document z\_mat\_manual.pdf.*

*The following file is that used in the case-test zmat001a:*

```
% file zmat001a.33
*** material
*integration theta_method_a 1. 1.e-9 50
*** behavior gen_evp

**:**

**U2.10.01-B Page**

**: 5/8**

### *2.2 Characteristics of driving orders and profile of study of Code\_Aster*

*The use of Zmat is translated for the user of Code\_Aster in the following way:*

- Under key word COMP\_INCR of STAT\_NON\_LINE, it is necessary to specify RELATION='ZMAT', for to go to read the file containing the Zmat data. This file makes it possible to describe the parameters material.*
- Toujours under COMP\_INCR, a key word UNIT makes it possible to define the logical unit on which have comes to read to card-index it Zmat and of course the usual key words: GROUP\_MA, DEFORMATION (SMALL or PETIT\_REAC for the moment),*
- Key word NB\_VARI (under COMP\_INCR) makes it possible to specify the number of internal variables behavior. The number of internal variables can be larger than necessary (it storage of the internal variables will occupy more place than necessary in memory), but of course not lower than the number really used (Zmat then provided an error message). It a number can be calculated thanks to the Zpreload utility, whose example of call via python is given in the test zmat001a.*
- In astk, compared to a traditional study, it is enough to add the Zmat file and to associate it it logical number of unit defined in the key word UNIT.*
- Dans le cas d'une calcul de STAT/DYNA\_NON\_LINE en continuation, il est nécessaire de penser à fournir à nouveau à card-index it Zmat in the profile of study. The test zmat003a makes it possible to illustrate this point.*

### *2.3 Examples*

*The case-tests zmat001 with zmat004 validate the coupling between Code\_Aster and Zmat, but constitute*

*also a base of examples of implementation.*

· *zmat001: test of traction-shearing with a law of Chaboche (similar to the test ssnv101 with VISC\_CINI\_CHAB) in plane deformations (modeling A) and 3D (modelings B and C).*

*One also finds a possibility there of using Zpreload to recover the number of variables intern Zmat behavior.*

· *zmat002: thermoplasticity in simple traction (VMIS\_ISOT\_TRAC), modeling A in axisymmetric, modeling B in plane constraints. The interest of this test is to describe variation of the coefficients with the temperature.*

· *zmat003: test of traction-shearing using a law defined in the file zmat003a.32 (see following paragraph). This test also validates the use in CONTINUATION.*

· *zmat004: test of comparison enters the model MONOCRYSTAL and its analogue Zmat.*

*3*

*To define a new behavior in Zmat*

*The new behavior is defined in a file which will be compiled, independently of Code\_Aster, in order to produce a dynamic library, used by the Zmat library principal at the object time.*

*Neither the file “source”, nor the built library need to appear in the profile astk.*

### 3.1

#### *To write a new behavior in Zmat*

*The writing of a new behavior is done using a high-level language (Zebfront, allowing tensorial operations...) on the basis of C++. One will refer to the documentation of Zmat for the description of syntax: [devel\\_manual.pdf](#).*

#### **Warning**

*Zmat imposes that the name of this file starts with a capital letter and has the extension “.z” during the compilation run.*

*Here the file (named `Chab1.z` for the following examples) defining the behavior `chab1` used in the test `zmat003` (file `zmat003a.32`), equivalent of behavior `VISC_CIN1_CHAB` of `Code_Aster`:*

```
#include <Elasticity.h>
#include <External_parameter.h>
#include <Basic_nl_behavior.h>
#include <Basic_nl_simulation.h>
#include <Flow.h>
#include <Criterion.h>
#include <Isotropic.h>
#include <Print.h>

### **3.3**

#### ***Use of the behavior user***

*In the profile of study astk, one provides like previously a file containing the value of parameters for the behavior user. The name chab1 is important and must correspond to name provided to the attribute @Name of the file .z (here the file zmat003a.33):*

**\*\*\* behavior chab1**

**\*\* YE isotropic**

*Young 195000.*

*fish 0.3*

**\*\* model\_coef**

*K 600.0*

*N 3.5*

*C 0.0*

*D 0.0*

*R0 30.0*

*Q 270.*

*B 100.*

**\*\*\* return**

*One provides the command file in which it is necessary to define the variable of environment ZEBU\_PATH to indicate to Zmat where is the dynamic library which one has just compiled. One finds then in the file (extracted from zmat003a.com m):*

```
# definition of variable ZEBU_PATH  
importation bone  
os.environ ["ZEBU_PATH"] = "/home/user/repertoire"
```

*[...]*

```
# definition of the elastic properties of material  
# which must be coherent with that of the Zmat file  
ACIER=DEFI_MATERIAU (ELAS=_F (E = 195000. ,  
NAKED = 0.3),)
```

*[...]*

```
# use of the behavior in nonlinear calculation  
# UNIT must correspond to the value defined in astk  
CALCNL=STAT_NON_LINE (...,  
COMP_INCR=_F (RELATION = "ZMAT",  
UNIT = 33,  
NB_VARI = 26,  
DEFORMATION = "SMALL"),  
..., )
```

## **1 General information**

### **1.1 Presentation**

#### **Grace**

**Grace is a tool of graphic layout of curve (WYSIWYG) under licence LPG available on system standard Unix/Linux and related to other platforms (of which Windows). Strong points of Grace are as follows:**

- modification of the layouts in a graphic environment by contextual menu;**
- very precise control of the elements on the curves (traced, legends, axes, etc...);**
- re-examined quality “publication”;**
- export (E) PS, pdf, JPG, png (according to platform and installation);**

**Internet site of Grace is <http://plasma-gate.weizmann.ac.il/Grace>**

### **1.2**

#### **Object of this tutorial**

**The goal of this tutorial is to make it possible the user of Aster to rather quickly take in hand one powerful tool allowing him to plot curves.**

**This tutorial presents the two great stages to plot the curves:**

- to import and modify the data;**
- to specify the graphic aspects of the curves.**

### **1.3**

#### **Other sources of information**

**Only basic handling will be presented here; for a more precise description of functionalities of Grace, the reader will refer to the user guide (in English): <http://plasma-gate.weizmann.ac.il/Grace/doc/UsersGuide.html>**

*A FAQ is diponible on the site of Grace: <http://plasma-gate.weizmann.ac.il/Grace/doc/FAQ.html>*

**2**

## ***Creation/importation of data***

*This paragraph describes the part “given” of Grace. There are three ways of obtaining data to be traced in Grace:*

- by importation of data in files;*
- by creation of data (via sampled mathematical functions);*
- by duplication and modification of existing data.*

### ***2.1 Importation***

*Grace is able to import curves starting from textual files. These files should not contain that data (except for lines starting with # which are regarded as lines comments).*

*The data must be in column (separated by spaces or tabulation characters). Attention, a file can contain one “storage block”, i.e of the data on several columns and several lines (contrary to the files .dogr previously used by the Agraf tool).*

*Instruction manual*

***:***

***U2.51.01-A Page***

***: 3/22***

*Grace can read the various columns in the form:*

- only one curve (“individual set”): XY, Grace takes column 1 for X and column 2 for y; or well a curve XYDX, Grace takes X then in column 1, y in column 2 and dx (uncertainty on X) in column 3; multiples types of curves are envisaged;*
- several curves which shares the same X-coordinates (“NXY”): column 1 contains the X-coordinates common to all the curves; the columns (i+1) the ordinates of the curve (I) contain.*
- several curves with X-coordinates potentially different (“block dated”): one interface opens to define the number of column where are arranged X-coordinates or ordered of each curve - an entry “index” allows to define a curve more ((1, y1), (2, y2),..., (N, yn)) -.*

*In practice, the importation is done starting from the menu “Dated/Import/Ascii...”, who opens the window of dialogue above. One notes:*

- the part “selector of file” in top;*
- the possibility of sending the data imported on the graph of its choice (cf further the organization from Grace in graphs and curves): “Read to graph”*
- selection of the type of importation (“Load have” and “standard Set”). In the case of an importation in the form of “block dated”, afterwards validation by “ok”, Grace analyzes the file and a news fenestrate opens which makes it possible to affect the various columns. One will notice that in top of this window, Grace indicates the number*

*columns and lines which it found in the file. One will note also that one can define the type of the curve by “standard Set”. Lastly, the difference between the button “apply” and “accept” is interesting to know: “apply” load the curve while leaving limp of dialogue open (to be used if the user has several curves to be imported of the same file), while " accept " load the curve and firm limps it of dialogue (to be used for the importation of only one curve starting from the same file).*

Creation of data per mathematical function*

*To define a curve, enchainner is needed the following orders:*

- *Edit/Dated sets...*
- *Right Clic in the zone in lower part of “Dated sets”;*
- *Chosir “Create New/By Formula”, which opens limps it following, that should be filled. By example, to trace  $\sin(X) + 2.5$  from -10 to 10 in 100 steps;*
- *After “Accept” then “Closed”, possibly button “Autoscale” (tool (see paragraph [§5] detailing the bar of tool of Grace) “ACE” on the right of the magnifying glass of the zoom) to post the curve with the good scale.*

*One can also use tests (use of the characters “?” equivalent of a “then” and”: “equivalent of a “else”) in the formulas, as on the following examples:*

***To duplicate/modify a curve, there are two solutions. Some it is the adopted solution is necessary to open the operator console. With the first solution, one starts by duplicating the curve to modify it in the operator console; with the second, all is done in the console of order.***

### ***2.3.1 Duplication then modification in the console***

***It is supposed that there is at least a curve available in Grace.***

***The sequence of orders is as follows:***

- Edit/Set Operations,***
- to select G0 like graph to be copied, S0 like curve to be copied and G0 like graph of destination and “Copy” like operation to be carried out, finally “accept”,***
- it is now necessary to modify the column Y of the set S1; that is done by opening the console of order: Window/Commands, and to type “s1.y = s0.y^2” to obtain the preceding curve squared (cf [§5.4] of User' S Guides for a complete list of the authorized operations).***

***Instruction manual

***:***

***U2.51.01-A Page***

***: 8/22***

### ***2.3.2 creation in the console***

***One opens the operator console immediately: Window/Commands.***

- One creates initially the curve by specifying the number of points (identical to the number of points set S0) “s1 length s0.length”,***
- then one duplicates the X-coordinates “s1.x = s0.x”,***
- finally one defines the ordinates “s1.y = s0.y^2”***

***Organization of Grace in graphs and curves***

**3.1 General**

***For Grace, a graph is a graph which can contain several curves, a “project” Grace (being able to be safeguarded in a file carrying the extension “agr) can contain several graphs.***

***The graphs are named G0, G1,...***

***The curves are named S0, S1,...***

3.2

***Management of the graphs***

***The user can manage the graphs in each list of selection of graphs (for example in menus Edict/Arranges Graphs, Edit/Set Operations, Edit/Overlay Graphs, Plot/Graph Appearance as on the illustration below or Dated/Import/Ascii).***

***In the zone in lower part of “Graph”, one finds a list of graphs here (, the project comprises two graphs, the first including/understanding three curve, the second including/understanding only one curve). It will be noted***

***“(–)” in front of the first graph, which means that the first graph “is hidden” (hidden, i.e not posted), while it (+) in front of the second means that it is posted (showed). Graphs put in intensified brightness are the graphs concerned with the action in progress: here, modification of the***

## **graph**

*relate to G0 (even if it is hidden!). In the same way, with the importation of a curve:*

### **Instruction manual**

**U2.51 booklet: Tools for postprocessing**

**Author (S):**

**P. Key BADEL**

**:**

**U2.51.01-A Page**

**: 10/22**

*the curve which the user prepares to import will go in the G0 graph (like previously, if graph being hidden, the imported curve will not be posted).*

*In certain menus (Stud/Graph Appearance for example), it is possible to select several graphs (in a usual way: Left Ctrl + click for a selection of graph “one by one” or Shift + left click on the first and last element of a contiguous list or left click + displacement of mouse on a list....), while other menus (Dated/Import/Ascii for example) authorizes only one only selected graph.*

*An order important (and not very intuitive) is the right click on the list of the graphs, which opens a menu comprising the following orders:*

- x-ray to: to define the active graph (useful if several graphs are posted: the active graph is that which receives the actions when the user uses the icons, in the same way to manage them curves of a graph, it is necessary that the graph is the active graph);*
- hide: hide the graph;*
- show: post the graph;*
- duplicate: duplicate the graph and all its curves;*
- kill: destroyed the graph;*

- *swap: exchange two graphs (one needs two graphs placed in intensified brightness);*
- *create new: create a new graph (vacuum).*

*In short, to create a new graph, it is necessary to open the list of the graphs (while using for example Stud/Graph Appearance), to click on the right on the list of the graphs and to choose “Create New”). One will note that there is not menu making it possible to make this action directly.*

*: 11/22*

*3.3*

*Management of the curves*

*The principle of management of the curves is about the same one as that concerning the graphs. Grace*

*post the list of the curves (active graph: attention, once again, the active graph is not inevitably visible!) in the menus which handles the curves: Edict/Dated Sets, Edit/Set Operations, Dated/Data set operations, Plot/Set Appearance as on the following illustration:*

*The active graph is G0 here (he is recalled in prefix of the curves in the list), he has three curves (one will note the mention, between hook, behind the name of the curves of dimension here 2 for X and Y and the length here, the curves have all 150 points -).*

*In the list of the curves, right click opens a menu:*

- *hide: hiding place the curve;*
- *show: post the curve;*
- *bring to face: put the curve at the foreground;*
- *send to back: put the curve at the background;*
- *duplicate: duplicate the curve;*
- *kill: remove the curve;*
- *kill dated: remove the data but not the curve, i.e all working is preserved, what can be very practical if the user has two identical graphs to realize from different data: it is enough to create a graph, then to remove all the data with "kill dated ", to import the second set of data: the two graphs will have the same one exactly aspect;*
- *swap: exchange the position of the two curves*
- *edict: publish the data;*
- *create new: create a new curve;*
- *pack all sets: ?*
- *selector operations: left preferably menu for the posting of this list of curves.*

*Instruction manual*

## 4.3

### **Working of the curves**

*Working of the curve is controlled starting from small Plot/Set Appearance. In limps of dialogue opened by this menu, there is first of all a list of the curves contained in the graph running, which makes it possible to select the curve which one publishes the properties.*

*To attach a legend to a curve, it is necessary to define the text of the legend in the Main mitre (Legend, String). It will be noted that it is possible to carry out complex legends.*

*One can choose the style of line, his color and his thickness as well as the symbols used for to materialize each point in the mitre Hand (Line Properties and Symbol Properties). Definitions more precise can be added in the mitres Line and Symbols respectively.*

***Use of the bar of tool***

*The bar of tool vertically posts in top on the left Grace window:*

- *The magnifying glass allows zoomer by defining a zone in the mouse;*
- *The icon “HAVE” (for autoscale), allows to redefine framing (zoom) automatically.*

- Buttons “Z” and “Z” are used for die-zoomer and zoomer respectively.
- The arrows are used to move the traced zone.
- AutoT: automatic definition of the graduations starting from the curve more near to the clicked point.
- AutoO: automatic framing starting from the curve nearest to the point clicked
- ZX, ZY: like the magnifying glass but in only one direction (X or Y)
- AX, AY: automatic framing in only one direction (X or Y)

The other buttons relate to the management of the pile of graphs and will not be explained here.

***Tricks and easy ways***

**6.1**

***Extended characters, in particular Greek alphabet***

*It is possible to use other pig iron and cast iron of characters that the standard cast iron in any zone of text*

*(legend of curve, label of axes, etc...). In particular, it is possible to use the cast iron “Symbol” for to insert Greek characters.*

*For that, if in the field "String" of the legend one puts the chains following "test \ F {Symbol} test \ F {Arial} test ", like that:*

*one obtains a legend which resembles that (the order \ F {X} changing the cast iron)*

*One will find in User' S Guide in the paragraph the 7.1 various orders allowing of to control working of the zones of text (in particular pig iron and cast iron, size, the color, etc) and with paragraph [§6.1] the mechanism of definition of different the pig iron and cast iron usable by Grace.*

## **6.2**

### **Not or comma?**

*By defect, Grace is based on the environment user to know if it must represent the figures decimal with a point or a comma. On the majority of the recent systems, in France, it will use thus the comma. If it is necessary to print curves with points, under linux, it is necessary to make following handling: before launching Grace, making "export LC\_NUMERIC=POSIX" or "setenv LC\_NUMERIC POSIX " following Shell used.*

## **6.3 Batch**

*It is possible to do without the graphic interface, in particular for the repetitive tasks, one will find examples of the use of the batch in the turorial:*

*<http://plasma-gate.weizmann.ac.il/Grace/doc/Tutorial.html>*

**U2.51 booklet: Tools for postprocessing**  
**Document: U2.51.02**

**Layout of curves with Code\_Aster**

**Summary:**

**This document explains how, starting from a computation result, one can produce tables or functions, to extract the values from these tables or functions, to handle them, and finally lastly to use the orders of impression to plot curves.**

**If you have of a function or a table and that you wish simply to represent it in form from a curve, go directly in the paragraph [[§ 4](#)], and [consult documentations of IMPR\\_FONCTION \[U4.33.01\] and of IMPR\\_TABLE \[U4.91.03\]](#).**

***26/05/05***

### ***Author (S):***

***Key COURTEOUS Mr.***

***:***

***U2.51.02-A Page***

***: 2/10***

### ***Notice preliminary***

***Postprocessing must be carried out in CONTINUATION and not following calculation.***

***Several reasons with that:***

- in the event of error, one does not lose the hours of calculation which made it possible to reach it result,***
- one can carry out many postprocessings directly while launching Stanley on the base result of calculation (see astk [U1.04.00] or STANLEY [U4.81.31]),***
- to simplify postprocessing, one can use the possibilities offered by Python who require to be in PAR\_LOT='NON' in CONTINUATION what prevents the use of eficas for this type of postprocessing, whereas it is simpler to use eficas to build the principal data file.***

## ***1***

***To extract the data using the orders Aster***

***It is supposed that the user has a computation result obtained to leave, for example, order MODE\_ITER\_SIMULT for a calculation of clean modes, STAT\_NON\_LINE for a calculation nonlinear statics, or DYNA\_NON\_LINE for a nonlinear dynamic calculation...***

***One has in all the cases a concept result which will be for example of mode\_meca type, mode\_flamb, dyna\_trans, tran\_gene, evol\_elas, evol\_noli, evol\_ther, etc according to order used and which contains fields of values that one wishes to represent in the form of curves.***

## ***1.1***

***To produce a function or a table***

## **Recall**

*A function is made up of two lists of values, X-coordinates and ordered; X-coordinates are necessarily monotonous.*

*A table is not necessarily a standard agglomerate of values in the same way to which one reaches via a parameter, "name of column". In the use of the tables which us interest here, one will generally produce columns of real numbers; their variation is unspecified.*

*For more details on than is a table, one will be able to consult the documentation of IMPR\_TABLE [U4.91.03].*

*The values can be extracted by using the following orders:*

- RECU\_FONCTION [U4.32.03]: product a function starting from a result, of a field, one count... Example: temporal evolution of a component of a field in a particular point.*
- POST\_RELEVE\_T [U4.81.21]: product a table starting from a result or of a field. One can to extract a quantity associated with the components from a field (a component, one invariant...) in certain particular points or along a way not necessarily rectilinear.*
- MACR\_LIGN\_COUPE [U4.81.13]: product a table starting from a result or of a field length of a line of cut (straight line made up of regular segments).*
- RECU\_TABLE [U4.71.02]: product a table starting from the values of one or more parameters of a result. For example: evolution of the parameter of piloting during a calculation. One can also to extract a table from some structures of particular data.*
- CREA\_CHAMP [U4.72.04]: allows to extract a field from a structure of data result. This can be useful when an order cannot treat certain results. One can by example then to recover a function via RECU\_FONCTION/CHAM\_GD.*

**1.2**

**To treat storage blocks**

**A storage block is simply a table of values to NR lines, P columns.**

**In certain cases, one lays out of one or more files made up each one of one or more blocks of data, separated by lines from text. To build functions starting from such files, one can use LIRE\_FONCTION [U4.32.02].**

**For example, one carries out a parametric study, each calculation produces a table which comes to enrich**

**a file of result; the file can also be built by a single calculation or manually, it does not matter. Such a file could resemble that:**

**WITH PARA=1.23**

**INST COOR\_X DY**

**1.00000E+00 1.00000E+01 -3.02717E-2**

**1.20000E+00 1.00000E+01 -8.14498E-2**

**1.40000E+00 1.00000E+01 -7.97278E-2**

**1.60000E+00 1.00000E+01 -3.86827E-2**

**1.80000E+00 1.00000E+01 -8.48309E-2**

**2.00000E+00 1.00000E+01 -9.37561E-2**

**2.20000E+00 1.00000E+01 7.18293E-2**

**2.40000E+00 1.00000E+01 6.05322E-2**

**WITH PARA=1.98**

**INST COOR\_X COOR\_Y DX DY**

**1.00000E+00 1.00000E+01 0.00000E+00 -3.02717E-2 2.07127E-01**

**1.10000E+00 1.00000E+01 0.00000E+00 -8.14498E-2 4.14928E-01**

**1.20000E+00 1.00000E+01 0.00000E+00 -7.97278E-2 7.92728E-01**

**1.80000E+00 1.00000E+01 0.00000E+00 -7.86827E-2 6.88227E-01**

**2.45000E+00 1.00000E+01 0.00000E+00 8.48309E-2 3.43029E-01**

**There are several blocks which inevitably do not have the same number of columns.**

**Let us suppose that one wants to compare displacement DY obtained with the two values of PARA, one**

**will use for example:**

**fDY1=LIRE\_FONCTION (**  
**TYPE=' FONCTION',**  
**INDIC\_PARA= (1,1,), # the X-coordinates are taken in block 1, column 1**  
**INDIC\_RESU= (1,3,), # the ordinates are taken in block 1, column 3**  
**UNITE=38,**  
**NOM\_PARA=' INST',**  
**NOM\_RESU=' DY',)**

**fDY2=LIRE\_FONCTION (**  
**TYPE=' FONCTION',**  
**INDIC\_PARA= (2,1,), # the X-coordinates are taken in block 2, column 1**  
**INDIC\_RESU= (2,5,), # the X-coordinates are taken in block 2, column 5**  
**UNITE=38,**  
**NOM\_PARA=' INST',**  
**NOM\_RESU=' DY',)**

**# traced traditional of two functions with IMPR\_FONCTION:**

**IMPR\_FONCTION (FORMAT=' XMGRACE',**  
**UNITE=29,**  
**COURBE= (\_F (FONCTION=fDY1,**  
**LEGENDE=' PARA=1.23',),**  
**\_F (FONCTION=fDY2,**  
**LEGENDE=' PARA=1.98',),),**  
**TITRE=' DY=f (T) ',)**

*To transform the values of a table or a function into python objects*

*Notice*

*The treatments in Python which are used from now force to be in PAR\_LOT='NON' in CONTINUATION (or BEGINNING).*

*The object is here to recover the values of a table or a function in a Python object for to handle then. Let us note that it is sometimes practical to produce a function starting from the data of a table, by filtering possibly certain lines of the table; it is a use of RECU\_FONCTION [U4.32.03], which we will not approach here.*

*On the objects of the function type, one has the methods:*

- Valeurs to recover the X-coordinates and the ordinates in 2 lists Python of realities.*

*With the data of the preceding paragraph:*

```
>>> lx, ly = fDY2.Valeurs ()
```

*One obtains:*

```
>>> print lx
```

```
[1.0, 1.1, 1.2, 1.8, 2.45]
```

```
>>> print ly
```

```
[0.207127, 0.414928, 0.792728, 0.688227, 0.343029]
```

- Absc and Ordo makes it possible to recover the X-coordinates and the ordinates separately.*

```
>>> lx = fDY2.Absc ()
```

```
>>> ly = fDY2.Ordo ()
```

*One can reach the contents of a cell of a table with [nom\_parameter, numéro\_ligne]:*

```
>>> print ["DY", 2]
```

```
-8.14498E-2
```

*One can also transform object (JEVEUX) table into an authority of the Python class Counts.*

```
>>> tabpy = tab.EXTR_TABLE ()
```

*The document [U1.03.02] details the Python methods available on the objects of the Table type. For the extraction of the values, one has in particular a method been worth () which turns over a dictionary*

*whose keys are the names of parameters (ex "DY") and the values the lists of the values of the table.*

*Caution*

*The Python lists are indexed of 0 with n-1 (for N elements), the equivalent of ["DY", 2] is thus tabpy ["DY"] [1]!*

*For the layout of curves starting from lists of real Python, to see [[§ 4](#)].*

### *3*

#### *To handle the values in Python*

*One gives here some examples of handling of the values obtained previously in the form of lists or of Numeric tables.*

*Numeric is optional a Python module (i.e. not included with the distribution of Python provided on [www.python.org](http://www.python.org), will be it perhaps in Python 2.5) but essential to use Code\_Aster, one can thus to make Numeric importation on all installations of Code\_Aster.*

*Instruction manual*

*Author (S):*

*Key COURTEOUS Mr.*

*:*

*U2.51.02-A Page*

*: 5/10*

### *3.1*

*With lists Python*

*The Python lists are easily easy to handle by using the loops. Let us take the example of the note [U2.51.01] for  $10. < X < 10.$  in 100 steps:*

*y = -1.5*

*if sin (X) <0*

*y = -5.*

*if not*

*One thus seeks to build two lists of realities, lx and ly.*

*As always in Python, it is possible several to make, more or less simply, more or less elegantly!*

```
x0=-10.
pas=20. /100
lx= []
or
lx= [x0+i*pas for I in arranges (101)]
for I in arranges (101):
lx.append (x0+i*pas)
```

```
def F (X):
yew sin (X) <0.:
return -1.5
else:
return -5.
```

```
ly=map (F, lx)
who applies the function F to all the elements of lx
```

*One can plot this curve by using the key words X-COORDINATE and ORDINATE of IMPR\_FONCTION ([cf \[§ 4\]](#)).*

### 3.2

*With Numeric tables*

*The handling of the data in the form of Numeric tables is simplified by the use very powerful operations (called ufunc) on the whole table (in the following example one uses sin ()). Numeric also manages the tables with several dimensions.*

*By taking again the preceding example:*

```
from Numeric import *
lx = arrayrange (- 10. , 10.+0.2, 0.2, Float)
ly = array (map (F, lx))
```

*or without using F:*

```
ly = -1.5*less (sin (lx), 0.) + (- 5.)* (1. - less (sin (lx), 0.))
```

*Let us note that map () turns over a list and not a Numeric table. The second expression is between*

*10 and 20 times faster on very large tables (105 106 terms), which is however rather little often the case of the functions or tables resulting from Aster.*

*One can plot this curve by using the key words X-COORDINATE and ORDINATE of IMPR\_FONCTION in*

*taking care to convert Numeric tables into list, for example (cf [[§ 4](#)]):*

*X-COORDINATE = lx.tolist ()*

## ***4.3***

### ***Layout of a great number of curves***

*In certain applications, one is brought to plot many curves. Let us suppose that one wish to compare our results with 50 points of measurement obtained in addition. It would be then tiresome of to define 50 files in astk and to use 50 different logical units in the command file! It is then enough to use the type "repe" in result in astk (cf [U1.04.00]):*

*One proceeds then thus in the command file in PAR\_LOT='NON' in CONTINUATION:*

*# definition of the 50 groups of nodes of examination*

*lgrno = ["point01", "point02", ..., "point50"]*

*# for each node of examination...*

*for not in lgrno:*

*links = 29*

*# the DEPL\_point0i.dat files will be recopied in curved Resultats/*

*DEFI\_FICHER (UNITE=unit, FICHER= `./REPE\_OUT/DEPL\_ "+point+" .dat')*

*tab=POST\_RELEVE\_T (*

*ACTION=\_F (ENTITLES = "VonMises",*

*RESULT = resM,*

*NOM\_CHAM = "EQUI\_ELNO\_SIGM",*

*NOM\_CMP = "VMIS",*

*TOUT\_ORDRE = "YES",*

*GROUP\_NO = not,*

*OPERATION = "EXTRACTION",),)*

*IMPR\_TABLE (*

*UNIT = links,*

5

*Some useful easy ways*

*One proposes here some handling of the data of the recurring tables in Python when of one wants to go further in the generation of curves since Code\_Aster.*

***To extract from the table resulting from POST\_RELEVE\_T the list from the nodes from postprocessing:***

*When one post-draft a size on a group of nodes (with more than one node) for several moments, the nodes appear for each moment, it is thus necessary to extract the list from these nodes without repetition.*

```
tabpy = tab.EXTR_TABLE ()
```

*Creation of the object Counts Python*

```
tno = tabpy.NOEUD.values ()
```

*One extracts the values from the column NODE*

```
lno = dict ([(i.strip (), 0) for I in tno]) .keys ()
```

*Powerful method to eliminate them*

*let us double with a dictionary*

```
lno.sort ()
```

*Sorting by ascending order*

***To build one or more key words dynamically:***

*This can in particular be useful to inform the key word factor FILTERS IMPR\_TABLE in function context; one builds in this case a dictionary which is then provided in argument of order.*

*This:*

```
IMPR_TABLE (
```

```
UNIT = links,
```

```
COUNT =,
```

```
FORMAT = "XMGRACE",
```

```
FILTER = (_F (NOM_PARA=' NOEUD',
```

```
VALE_K = "N4"),
```

```
_F (NOM_PARA='NOEUD',  
VALE_K = "N4",),),  
NOM_PARA = ("INST", "VMIS"),  
)
```

*is equivalent to that:*

```
mfac = {"FILTER": [{"NOM_PARA": "NODE", "VALE_K": "N4"},  
{"NOM_PARA": "ENTITLES", "VALE_K": "example"},],  
"NOM_PARA": ["INST", "VMIS"],  
"UNIT": links,  
"FORMAT": "XMGRACE",}
```

```
IMPR_TABLE (  
COUNT =,  
** mfac  
)
```

*The interest being of course to be able to build the dictionary as one wishes it.*

### **Notice**

*The key words factors (here FILTER) can be built by using *\_F* (mot-clé = value), but it is more flexible to see them like a list of dictionaries.*

***Summary:***

***This file makes it possible to describe a grid of Code\_Aster. It can be built by an automatic interface between a maillor and the code, but can also be written with the hand. It contains:***

***.  
a possible title,***

***.  
a list of nodes with their co-ordinates,***

***.  
lists of meshes, each mesh is described by the list of the nodes which defines its topology, and sound orientation,***

***.  
groups of nodes and groups of meshes.***

***Note:***

***A concept of the grid type, once read on the file of grid, can be enriched using operators of Code\_Aster by information which cannot be currently described in the file of grid. This relates to in particular the static under-structuring. It is of more possible, now, of***

*to create groups of nodes or meshes under study.*

*1*

*Structure of the file of grid*

*The file of Aster grid is read first line until the first occurrence of a line begin with the FINE word. This key word is obligatory.*

*The file of Aster grid consists of a succession of under files of grid, independent.*

*UNDER FILE 1*

*UNDER FILE 2*

*UNDER FILE NR*

*END*

*The file of Aster grid is a file with format, within the meaning of FORTRAN:*

.  
*the length of line is limited to 80 characters (any information starting from column 81 is simply been unaware of);*

.  
*the 26 tiny a-z are converted automatically in capital letters,*

.  
*the white character ““and the comma”,” are only the recognized separators,*

.  
*the character % is a character reserved to indicate the beginning, until the end of the line, of one comment,*

.  
*the numerical data are interpreted in free format:*

*1 = 1. = 1.0 = 1.E+0 = .1E1 = 10.D-1*

*The file grid must contain at least:*

.  
*a subfile of co-ordinates of nodes COOR\_2D or COOR\_3D, defined by 2 or 3 numbers realities in a single orthonormé Cartesian reference mark.*

.  
*a subfile by type of mesh used.*

*It can contain, moreover, and that is recommended, a subfile TITRATES. It is practically essential to define, at the time of the grid, the subfiles of groups of meshes GROUP\_MA and of the subfiles of groups of nodes GROUP\_NO.*

*It will be retained that the assignment of a type of finite element, can be done only on one mesh (or exceptionally on a node for the discrete elements) described in the file grid.*

*loadings or the boundary conditions are affected on meshes or nodes according to case.*

*Description of the file of grid of Code\_Aster*

**Date:**  
**06/06/05**  
**Author (S):**  
**J. Key PELLET**  
**:**  
**U3.01.00-D Page**  
**: 4/16**

**2**  
**Structure of under file**

**Under file starts with a key word and is finished by the key word imposed FINSF:**

**KEY WORD**  
.....  
.....  
**FINSF**

**This description is sufficient for Aster. The most complete description is as follows:**

**.**  
**each under file comprises 3 parts:**

- 1) the heading of under file,**
- 2) contents of information,**
- 3) the end mark of under file (FINSF).**

**KEY WORD NOM= NBOBJ= NBLIGE= NBLIGT=**

**NUMIN= NUMAX=**

**1**

**AUTEUR= DATE=**  
**XX/XX/XX**  
**%**  
**COMMENTS**

**2**  
**---- INFORMATION ----**

### 3

#### **FINSF**

%

.

*The **KEY WORD** and **FINSF** (fine of under file) are obligatory because they delimit under file with interior of the file of grid.*

.

*The **NAME** is optional. When the key word is **GROUP\_MA** or **GROUP\_NO**, if **NAME** misses then the first character string met after these **KEY WORDS** will form the **NAME** of **GROUP\_MA** or of the **GROUP\_NO**.*

*By convention any character string which follows the characters % is interpreted like one comment.*

*Instruction manual*

*U3.0- booklet: Grid HT-66/05/004/A*

*Date:*

*06/06/05*

*Author (S):*

***J. Key PELLET***

*:*

*U3.01.00-D Page*

*: 5/16*

#### **2.1 The heading**

*The role of the heading is to provide total information on the contents of under file:*

***KEY WORD:** in addition to its role of delimiter of under file it informs about the nature of information which will follow. It must be in 1st line of under file **and tallied on the left.***

## **NAME:**

*it is used to indicate a whole of information. It must be in 1st line of the heading of under file. It is optional.*

*all the other key words are currently ignored by the operator  
LIRE\_MAILLAGE [U4.21.01].*

## **2.2**

### **List information**

*They are the information resulting from a maillor and written in free format.  
Information which this file must contain defines of the traditional entities of the method of finite elements:*

.

#### **nodes:**

*points defined by a **name** and their **Cartesian co-ordinates** in space **2D** or **3D**,*

.

#### **meshs:**

*plane or voluminal **named** topological figures (not, segment, triangle, quadrangle, tetrahedron,...), defined by the ordered list of the nodes who constitute them and to whom will be able to apply various types finite elements, boundary conditions or loadings. The order of nodes directs the mesh. This orientation must be scrupulously established because it is in particular used to lay down the orientation of the loadings (pressure,...).*

*One can also define groups of these topological entities.*

.

***groups of nodes:** named lists of names of nodes,*

.

***groups of meshs:** named lists of names of meshs.*

*Systematically, when one has to refer to nodes (or meshs), one will be able to make reference to groups of nodes (or groups of meshs).*

*The interfaces with the mailleurs automatically generate such groups (according to criteria clean with the maillor).*

*These groups facilitate the assignment of the material characteristics on the grid, of the conditions with the limits or the impression of the results. Indeed, at the time of such operations one refers to the nodes*

or with the meshes, which it is interesting to describe by group.

The operator of Code\_Aster *DEFI\_GROUP* [U4.22.01] allows to create groups a posteriori on all concept of the grid type already read.

It will be noted, that all entities handled in the code (nodes, meshes, groups of nodes, groups of meshes) **are named** and usable constantly by their name (**8 characters with maximum**). The classification of the entities is never clarified: it is useful only in-house for to point on the values of the various associated variables.

## 2.3

### **END of subfile**

It is word the “reserved” and obligatory *FINSF* which indicates the end of under file, which begin with a *WORD*

*KEY*.

***Document: U3.02.01***

***Interface file of grid GMSH with Aster***

***Summary:***

***GMSH is a tool for modelling, grid and postprocessing diffused under licence GNU LPG (achievable <http://www.geuz.org/gmsh>,, sources and documentation available on this site).***

***One describes here the principle of the interface which makes it possible to use in Aster a file resulting from GMSH.***

***This interface is implemented in Aster by order PRE\_GMSH [U7.01.31].***

***1***

***Use of GMSH***

***GMSH is a free or regulated tool for grid which integrates a modeller and functionalities of post-treatment. The modeller, easy to use, allows to prepare the grid of structures by geometrical constructions (creation of lines, surfaces, translations/rotations, extrusions...). The model of the structure can be built interactivement (with the mouse) or by a file of orders.***

***The documentation of GMSH is available at this address (it is possible that this direct bond is modified, pass by the banner page in this case): <http://www.geuz.org/gmsh/doc/texinfo/gmsh.html>.***

***The description of the geometry of the structure is contained in a file .geo, the produced grid is recorded with the extension .msh; this file which will be converted by order PRE\_GMSH with format Aster.***

***2***

## ***Entities GMSH and Aster groups***

***The modeller of GMSH handles points, lines, surfaces or volumes as entities geometrical (nonwith a grid). Grid GMSH is built by netting in this order the lines, them surfaces then the volumes supported on those.***

***In general, one handles parts of the grid to apply the properties materials, them boundary conditions or the loadings. To reach these under-parts of the grid, it is necessary to define “physical” in GMSH. A physical is made up of one or more geometrical entities. The interface GMSH-Aster produces a group of meshes for each physical: if the physical 21 consists of two volumes, the group of mesh GM21 contains the meshes of these two volumes.***

### ***Note:***

***In GMSH, one visualizes the entities constituting a physical by small Tools/Visibility and by selecting the number. One can then use order DEFI\_GROUP in Aster to handle a more explicit name of group of meshes.***

### ***Caution:***

***Physicals should not be created gathering others physicals, because that would lead to to produce double meshes.  
The number of the physicals must be lower than 1.000.000.***

**Interface file of grid IDEAS with Aster**

**Summary:**

**The purpose of this document is to describe the principle of interface IDEAS (SDRC) with Aster.**

**This interface is activated in Aster by procedure PRE\_IDEAS [U7.01.01].**

**The datasets of universal file I-DEASTM read again by the interface IDEAS-Aster are the dataset 151 (title), them**

**datasets 15, 781 or 2411 (co-ordinates of the nodes), the datasets 71, 780 or 2412 (description of the meshes),**

**the datasets 752, 2417, 2429, 2430, 2431, 2432, 2435 or 2467 (groups of nodes or meshes) and the dataset**

**735 (nodes or meshes attached to the curves, meshes area and meshes volume).**

*So versions I-DEASTM currently supported are versions 4, 5 and 6 as well as versions 1. , 2. , 3. , 4. , 5. , 6. , 7. , 8. , 9. and 10. of Master Series.*

*: 2/10*

*1 Vocabulary*

*IDEAS*

*“geometry”*

*together of geometrical entities on which the grid is based. They can be curves (“curve”) of surfaces (“mesh area”), of volumes (“mesh volume”).*

*“curve”*

*linéique geometrical entity being able to be made up of under-entities, segments, arcs of circles, options. The meshes which are based on these under-entities are segments with 2 or 3 nodes.*

*“mesh area”*

*geometrical entity surface broadside by “curves” on which the meshes rest of surface: triangles with 3 or 6 nodes or quadrangles with 4 or 8 nodes.*

*“mesh volume”*

*geometrical entity voluminal broadside by “mesh areas”. Meshes of volume which are based on these under-entities are hexahedrons with 8 or 20 nodes, pentahedrons with 6 or*

*15 nodes or of the tetrahedrons with 4 or 10 nodes.*

**“group”**

*an unspecified grouping (chosen by the user) of geometrical entities, nodes or of meshes; the user gives him a name.*

**“universal file”**

*the formatted file produces by IDEAS constitutes the data file of the interface. It contains all the geometrical grid (nodes and meshes), entities, groups and associations geometrical entities - grid.*

**“geometrical association entity - grid”**

*list nodes or meshes being based on a given geometrical entity.*

.  
*for each “curve”, the nodes which make it up,*

.  
*for each “mesh area”:*

-  
*the nodes which make it up,*

-  
*in 2D the meshes which make it up.*

.  
*for each “mesh volume”:*

-  
*nodes and the meshes which make it up.*

-  
*the nodes which make it up,*

-  
*in 3D the meshes which make it up.*

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U3.03.01-F Page**

**: 3/10**

**2**

**Interface of grid drank**

**The information contained in universal file IDEAS (for versions 4, 5 and 6 and poured them 1. , 2. , 3. , 4. , 5. , 6. , 7. , 8. , 9. and 10. of Master Series) are retranscribed in the file of grid. That relate to in particular the co-ordinates of the nodes, the meshes, the groups of nodes and meshes. It generally acts of simple transfers of subfiles, except for the meshes where a permutation nodes is necessary.**

**The names created by the interface are:**

**.**

**for the nodes: NO followed by the number of node IDEAS,**

**.**

**for the meshes: MA followed by the number of element IDEAS.**

**The meshes are gathered in subfiles of the homogeneous type: SORTED., QUAD., TETRA., PENTA., HEXA.**

**.**

**for the groups of nodes or meshes created by the user and named in IDEAS, it name is simply retranscribed in capital letters:**

**-**

**8 alphanumeric to the maximum (if not truncation of the name),**

**-**

**the underlined white is allowed.**

**Note:**

**The name of the group cannot start with "COUL\_" if not it is ignored by the interface (a message of alarm informs the user of it).**

**.**

**in IDEAS, one can assign a color to each mesh generated (by defect, the meshes are of green color). The colors are located by a number (for example 7 for green).**

**To keep this information in Aster, interface PRE\_IDEAS can generate groups**

***meshs of name COUL\_ n• color IDEAS containing all the meshs of color “n• color IDEAS ”. To generate these groups of meshs, the user must ask it explicitly by CREA\_GROUP\_COUL = “yes” in order PRE\_IDEAS.***

***Without explicit request of the user, these groups of meshs are not create in order to limit the number of groups of meshs and not to increase the size of the file unnecessarily of grid.***

***From geometrical associations entities - grid, the interface built:***

***GROUP\_MA associated with the “mesh volume” in 3D or with the “mesh area” in 2D. They bear the name M\_VOLUi or M\_AREAi for the geometrical entity of origin, number I.***

***GROUP\_NO associated with the “mesh volume”, “mesh area” or “curve”, which bears the names M\_VOLUi, M\_AREAi, CURVEi following the cases.***

***Note:***

***The mesh area and the mesh volume do not exist any more in versions 1. , 2. , 3. , 4. , 5. , 6. , 7. , 8. , 9. and 10. of Master Series. The user must thus take care to define the groups of nodes and groups of meshs which it needs for its study.***

***The interface of grid (PRE\_IDEAS) does not retranscribe the boundary conditions and loadings possibly present in the universal file.***

**Interface file of grid GIBI with Aster**

**Summary:**

**The use of GIBI (maillor of CASTEM 2000) can be done on workstation Unix/Linux according to**

*versions available.*

*One describes here the principle of the interface which makes it possible to use in Aster a file resulting from CASTEM 2000.*

*This interface is implemented in Aster by order PRE\_GIBI [U7.01.11].*

*1*

*Use of GIBI*

*CASTEM 2000 is a code of analysis of the structures by finite elements, which has a unit of functionalities dedicated to the grid in 2D and 3D. The whole of these functions of grid is known under name GIBI.*

*In the continuation of this document, one will name GIBI, the whole of the functions of grid like the whole of the orders for the visualization and the analysis of the results.*

*GIBI is available on a certain number of platforms Unix/Linux. It is a version diffused by the group “Codes of Mechanics” of EDF R & D /AMA within the framework of a contract with the ECA, it is available in remote loading on the <http://www.code-aster.org> site.*

*The memory allocated by GIBI is of 20 megawords per defect. For certain applications it is necessary to increase this size memory. With this intention, it is necessary to define variable ESOPE\_PARAM of following manner:*

*setenv ESOPE\_PARAM "ESOPE=x000000, NTRK=1024, LTRK=1048576"*

*or according to Shell used:*

*export ESOPE\_PARAM=' ESOPE=x000000, NTRK=1024, LTRK=1048576'*

*where X is the number of million words which one wishes.*

*The ECA produces a new version of GIBI each year. Before being brought into service on centralized waiter and to be diffused, this version is tested by the team codes on the whole of the tests Aster. Thus the "standard" version is currently GIBI version 2000, launched in interactive by order gibi2000.x.*

2

*Documentation on the use of GIBI*

*The documentation of GIBI can be obtained by carrying out GIBI with the data file according to:*

*NOTE;*

*END;*

*One recovers then in the listing of work, the list of the chapters corresponding to all the operators GIBI.*

*GIBI has a documentation in line which makes it possible to have the syntax of each operator by order:*

*INFORMATION name of the order;*

*but also the possibility of knowing the whole of the operators dedicated to the grid, gathered by functionalities (operators of creation of points, linear entities, surface entities and voluminal entities...) by the order:*

*INFORMATION DEBU;*

*This information is also available since a navigator Internet (the site depends on the local installation).*

***The Council of use of GIBI for Aster***

**.**

***Not to forget that each order ends in one “; ”,***

**.**

***Code\_Aster can read again the files created by GIBI having level 3, 4, 5, 6, 8, 9, 10, 11 or 13. This level is related to the change of format,***

**.**

***to think that it is not possible to impose the passage of the grid by a point or a line not being reproduced on external contour. To envisage the geometry division consequently,***

**.**

***to think that GIBI directs with its own conventions the various meshes. Elements can “be thus turned over” (from where negative jacobians and pressures to back!). In GIBI, the user has the operators OPPOSITE and TO DIRECT for modification orientation of elements. One will refer advantageously to order MODI\_MAILLAGE ([U4.23.04], key words ORIE\_PEAU\_2D/3D) to intervene on the orientation of the meshes in Aster,***

**.**

***operator PRE\_GIBI supposes that GIBI was carried out without error, i.e. second line of the file .mgib is “LEVEL LEVEL ERROR 0 DIMENSION...” In the contrary case, one carries out, nevertheless the interface, by emitting an alarm,***

**.**

***the file containing grid GIBI must be produced by the order “TO SAVE FORMAT grid ”; it is the only format read again by interface PRE\_GIBI.***

**4**

***Interface with Aster***

***The interface with Aster is activated by order PRE\_GIBI [U7.01.11].***

**5**

***Entities of grid GIBI and Aster***

***Maillor GIBI handles typified and named objects (cf Doc. of use of GIBI).***

***The types used are:***

- .  
***constants whole, real, text,...,***
- .  
***POINTS,***
- .  
***GRIDS (together of meshes).***

***Order PRE\_GIBI causes:***

- .  
***to write points (GIBI) in the form of nodes (Aster): the names of the Aster nodes are form: Nor where I is number GIBI of the corresponding point,***
- .  
***to write the meshes (Aster) contained in grids (GIBI): names of the meshes Aster are form: Mj where J is the sequence number of mesh GIBI in the file of result GIBI,***
- .  
***to write GROUP\_MA (Aster) corresponding to grids (GIBI) and of same names,***

***Note:***

***The groups of meshes contain only the meshes defining it indeed grid GIBI. They do not contain the meshes of the objects referred in this grid (edges for example).***

- .  
***to write GROUP\_NO (Aster) reduced to only one nodes and whose names are the names of points of GIBI.***

***Instruction manual***

## ***1 Discretization***

### ***1.1***

#### ***Degrees of freedom***

*For three modelings of beam into three-dimensional the degrees of freedom of discretization are, in each node of the mesh support, six components of displacement (three translations and three rotations). These nodes are supposed to describe a segment of average fibre of the beam.*

#### ***Finite element***

##### ***Degrees of freedom (with each node top)***

*POU\_D\_T*

*MECA\_POU\_D\_E*

*POU\_C\_T SEG2*

*MECA\_POU\_C\_T*

*BAR*

*SEG2 MECA\_BARRE*

## **1.3**

### ***Net support of the loadings***

*All the loadings applicable to the elements of beam and bar are treated by discretization direct on the mesh support of the element in displacement formulation.*

*No mesh support of loading is thus necessary for the edge of the elements of beam or of bar.*

## **1.4**

### ***Principal characteristics of modelings***

*Modeling POU\_D\_E (Right Beam of Euler) corresponds to the assumption of Euler-Bernouilli, i.e. the sections remain right and perpendicular to average fibre (assumption of great twinge).*

*Modeling POU\_D\_T (Right Beam of Timoshenko) takes into account the effects of shearing transverse.*

*Modeling POU\_C\_T is similar to POU\_D\_T with a curve (Beam Curves*

*Timoshenko).*

*Modeling BARS treats only the efforts and axial deformations.*

*The beam with warping is treated in [U3.11.04].*

*Instruction manual*

**2**

## ***Assignment of the characteristics***

*For these elements of structures 1D, it is necessary to affect geometrical characteristics which are complementary to the data of grid. The definition of these data is carried out with order **AFFE\_CARA\_ELEM** associated with the key words following factors:*

### **· BEAM**

*Allows to define and affect the characteristics of the cross section and the orientation of principal axes of inertia around neutral fibre.*

*Supported modelings: **POUT\_D\_T, POU\_D\_E, POU\_C\_T***

### **· BAR**

*Allows to define and affect the characteristics of the cross section.*

*Supported modeling: **BAR***

### **· DEFI\_ARC**

*Allows to define and assign to curved beams characteristics related to the curve of the element (radius of curvature and orientation of the plan of the arc).*

*Supported modelings: POU\_C\_T*

· **ORIENTATION**

*Allows to define and affect the principal axes of the cross sections of the elements of the type beam.*

*Supported modelings: POUT\_D\_T, POU\_D\_E, POU\_C\_T*

**Notice on the discretization:**

*With regard to the grid of the beams in meshes SEG2, it is useless to refine excessively these elements whose integrated formulation makes it possible to obtain solutions exact with the nodes in linear statics [R3.08.01]. In modal analysis and dynamics, one will take care to net sufficiently to represent the awaited modes, but without excess: it is necessary that the elements remain a sufficient length, according to dimensions of the section, so that the assumption of beam is valid.*

*For example, for a beam length 1, and a circular section of external ray 0.05 and thickness 0.01, 10 elements are enough to apprehend the 10 first correctly modes. But if one refines enormously, for example with 1000 elements, then each element of beam is very short: length 0.001 for an external ray of 0.05. Matrices elementary are very badly conditioned, in particular for element POU\_D\_E (for POU\_D\_T the terms of transverse shearing improve a little conditioning). With resolution, one then loses 8 decimals for the POU\_D\_E.*

U3.11.02-E Page

: 3/4

## **4 Possibilities**

### **non-linear**

#### **4.1**

##### **Law of behaviors**

Laws of behaviors specific to these modelings, usable under **COMP\_INCR** in **STAT\_NON\_LINE**, **DYNA\_NON\_LINE** and **DYNA\_TRAN\_EXPLI** are as follows (cf [U4.51.11]):

**/“ASSE\_CORN”**

Supported modeling: **DIS\_TR**

**/“WEAPON”**

Supported modeling: **DIS\_TR**

**/“DIS\_CHOC”**

Supported modelings: **DIS\_T**, **DIS\_TR**

**/“DIS\_CONTACT”**

Supported modelings: **DIS\_T**, **DIS\_TR**

**/“ELAS”**

Supported modelings: **2D\_DIS\_T**, **2D\_DIS\_TR**

In addition to the assignment of characteristics (**AFFE\_CARA\_ELEM**), the use of modelings **DIS\_T** and **DIS\_TR** with **STAT\_NON\_LINE/DYNA\_NON\_LINE/DYNA\_TRAN\_EXPLI** implies to define characteristics material (via **DEFI\_MATERIAU** and **AFFE\_MATERIAU**).

With *DIS\_CONTACT* and *DIS\_CHOC*, the elastic matrix is calculated with the characteristic of stiffness defined in *AFFE\_CARA\_ELEM*, while the tangent matrix is calculated via the behavior *DIS\_CONTACT* or *DIS\_CHOC*.

## 4.2 Deformations

Deformations available, used in the relations of behavior under the key word *DEFORMATION* for operators *STAT\_NON\_LINE*, *DYNA\_NON\_LINE* and *DYNA\_TRAN\_EXPLI* are  
(Cf [U4.51.11]):

*/"SMALL"*

The deformations used for the relation of behavior are the linearized deformations calculated on the initial geometry.

*/"PETIT\_REAC"*

The deformations used in the incremental relation of behavior are the deformations linearized calculated on the reactualized geometry.

## **Assignment of the characteristics**

*For this element of structures 1D, it is necessary to affect geometrical characteristics which are complementary to the data of grid. The definition of these data is carried out with order **AFFE\_CARA\_ELEM** associated with the key words following factors:*

### **· AFFE\_SECT**

*Allows to associate a plane grid of section an element beam.*

### **· AFFE\_FIBRE**

*Allows to associate a section made up of one or more specific fibres an element beam.*

### **· BEAM**

*Allows to associate a geometrical characteristic of torsion an element beam.*

### **· ORIENTATION**

*Allows “to turn” the plane grid of the section around the axis of the beam.*

## **Remarks on the characteristics of modeling:**

*1) Within the framework of modeling of a multifibre type, there are two “levels” of modeling. It y with the modeling known as “longitudinal” which will be represented by a beam (support geometrical SEG2) and a modeling planes section (perpendicular to the SEG2).*

*Operand **AFFE\_SECT** makes it possible to associate a plane grid of section an element beam.*

*Operand **AFFE\_FIBRE** makes it possible to associate a section made up of one or more specific fibres (defined by their position and surfaces) with an element beam.*

2) In general in the plane modeling of the section, several materials cohabit. By example, in a section concrete reinforced, there are at the same time concrete and reinforcements. In it case there, operator **CREA\_MAILLAGE** makes it possible to duplicate support E.F so that there is not that only one material by support.

3) The operand

**BEAM** is used to affect a geometrical characteristic of torsion (**JX**)

who cannot be calculated starting from the plane grid of the section. If the value is used **GENERAL** for the key word **SECTION** of the operand **BEAM**, it is necessary to give the characteristics (**CARA**) With, **IY** and **IZ** in addition to **JX** because operator **AFPE\_CARA\_ELEM** waits at least these four characteristics for a traditional beam.

Values (**VALE**) data with **A**, **IY** and **IZ** are not used by element **POU\_D\_EM**, because they are calculated starting from the plane grid of the section. On the other hand a checking of coherence of the information (**SURFACE** and **INERTIA**) provided on the one hand by **A**, **IY**, **IZ** and of other

leaves by key words **AFPE\_SECT** and **AFPE\_FIBRE** is carried out. The criterion of error is based on the error relating and is compared either with the default value or to that given by the user via key words **PREC\_AIRE** and **PREC\_INERTIE**. (Cf orders **AFPE\_CARA\_ELEM** key words **PREC\_AIRE** and **PREC\_INERTIE** of the operand **BEAM**).

4) The operand

**ORIENTATION** is used in general “to turn” the plane grid of the section around the axis of beam (**CARA** “**ANGL\_VRIL**”). Indeed, by defect, axis **X** (horizontal) plane grid of the section is confused with the axis there beam (see [Figure 3-a]).

## **4 Possibilities**

### **non-linear**

#### **4.1**

##### **Law of behaviors**

Laws of behaviors specific to this modeling, usable under *COMP\_INCR* in *STAT\_NON\_LINE* and *DYNA\_NON\_LINE* are as follows (cf [U4.51.11]):

**/"CORR\_ACIER"**

**/"LABORD\_1D"**

**/"PINTO\_MENEGOTTO"**

**/"VMIS\_CINE\_LINE"**

**/"VMIS\_ISOT\_LINE"**

**/"VMIS\_ISOT\_TRAC"**

**/"GRAN\_IRRA\_LOG"**

Moreover, it is possible for this modeling, which uses a monodimensional state of stresses to use the behaviors 3D by using key word *ALGO\_1D* (*METHOD = DEBORST*).

#### **4.2 Deformations**

Only the linearized deformations "*SMALL*" key word under *DEFORMATION* are available in relations of behavior (cf [U4.51.11]).

**Assignment of the characteristics**

**For these elements of plate or hulls, it is necessary to affect characteristics geometrical which is complementary to the data of grid. The definition of these data is carried out with order AFFE\_CARA\_ELEM associated with the key word following factor:**

**· HULL**  
**Allows to define and affect on the meshes, the thickness, the coefficient of shearing, offsetting,...**

**For the study of structures comprising of multi-layer materials it is necessary to affect them characteristics of each layer (thickness, type of material) and their stacking (orientation of fibres). The definition of these data is carried out with the order DEFI\_COQU\_MULT.**

**3 Loadings**  
**supported**

*The loadings available are as follows:*

· **FORCE\_ARETE**

*Allows to apply linear forces.*

*Supported modelings: DKT, DST, Q4G*

· **FORCE\_COQUE**

*Allows to apply surface efforts.*

*Supported modelings: DKT, DST, Q4G*

· **GRAVITY**

*Allows to define the acceleration and the direction of gravity.*

*Supported modelings: DKT, DST, Q4G*

· **PRES\_REP**

*Allows to apply surface efforts.*

*Supported modelings: DKT, DST, Q4G*

· **TEMP\_CALCULEE**

*Allows to apply a thermal loading of origin.*

*Supported modelings: DKT, DST, Q4G*

· **EPSI\_INIT**

*Allows to apply a loading of initial deformation.*

## **4 Possibilities non-linear**

**For modeling DKT only.**

### **4.1 Law of behaviors**

**Only modeling "DKT" has non-linear possibilities. Laws of behaviors specific to this modeling, usable under COMP\_INCR in STAT\_NON\_LINE and DYNA\_NON\_LINE are the relations of behavior in plane constraints available with modelings "AXIS" and "C\_PLAN". These relations are to be used with the key word ALGO\_C\_PLAN = 'DEBORST' (cf [U4.51.11]).**

### **4.2 Deformations**

**Deformations available, used in the relations of behavior under the key word DEFORMATION for operators STAT\_NON\_LINE and DYNA\_NON\_LINE are (cf [U4.51.11]):**

**/"SMALL"**

**The deformations used for the relation of behavior are the deformations linearized.**

**/"PETIT\_REAC"**

**The increments of deformations used in the incremental relation of behavior are linearized deformations of the increment of displacement in the reactualized geometry.**

**Note:**

**Attention, the calculation of the deformations using PETIT\_REAC is only one approximation of assumptions of great displacements. It requires to carry out very small increments of loading. To correctly take into account great displacements, and especially them great rotations, it is recommended to use modeling COQUE\_3D, with DEFORMATION='GREEN\_GR'.**

***Document: U3.12.03***

***Modeling COQUE\_3D***

***Summary:***

*Modeling COQUE\_3D presented here corresponds to a formulation of general kinematics of hulls and plates, of Naghdi-Reissner type, where the generalized constraints are obtained starting from the laws of three-dimensional behavior of constitutive materials [R3.07.04]. Contrary to modelings DKT-DST, Q4G corresponding to the formulations of elements of plate developed by J.L. BATOZ [bib1] which use plane finite elements, modeling COQUE\_3D makes it possible to carry out structural analyses hulls of forms*

*unspecified, with a good approximation of the geometry. Moreover this modeling is able of to represent great rotations of the structures [R3.07.05] under the assumption of small deformations.*

*The degrees of freedom are displacements and the rotations, taken with the nodes of the elements.*

*The nonlinear behavior is discretized by P2 polynomials, which allows a precise calculation of constraints.*

*It is usable for problems of structures three-dimensional hulls in linear mechanical analysis and nonlinear.*

*This formulation also exists for problems of sections, or revolution. It rests on elements 1D: (see [U3.12.02]).*

*Thermomechanical calculations are chained starting from the finite elements of thermal hulls (see [U3.22.01]).*

*Allows to apply a thermal loading.*

· **“PRES\_REP”**

*Allows to apply a pressure to a field of continuous medium.*

· **“ROTATION”**

*Allows to define the number of revolutions and the vector of rotation.*

### **4 Possibilities non-linear**

#### **4.1**

##### **Law of behaviors**

*All relations in constraints plane, usable under COMP\_INCR in STAT\_NON\_LINE, and DYNA\_NON\_LINE are available, like all the other relations 3D while using ALGO\_C\_PLAN = “DEBORST” (cf [U4.51.11]).*

#### **4.2 Deformations**

*Deformations available, used in the relations of behavior under the key word DEFORMATION for operators STAT\_NON\_LINE and DYNA\_NON\_LINE are (cf [U4.51.11]):*

**/“SMALL”**

*The deformations used for the relation of behavior are the deformations*

*linearized.*

*/“PETIT\_REAC”*

*The increments of deformations used in the incremental relation of behavior are linearized deformations of the increment of displacement in the reactualized geometry.*

*/“GREEN\_GR”*

*Allows to carry out calculations in great displacements and great rotations. deformations used in the relation of behavior are the deformations of GREEN-LAGRANGE.*

*Note:*

- Attention, the calculation of the deformations using PETIT\_REAC is only one approximation of assumptions of great displacements. It requires to carry out very small increments of loading. To correctly take into account great displacements, and especially them great rotations, it is recommended to use DEFORMATION=' GREEN\_GR'.*
- It is possible while using under the key word factor EXCIT (TYPE\_CHARGE=' SUIV') of to take into account a following pressure.*

U3.12 booklet: Mechanical elements of structure 2D  
Document: U3.12.05***

***Modeling SHB8***

***Summary:***

***This document describes for modeling SHB8:***

- degrees of freedom carried by the finite elements which support modeling,***
- the related meshes supports,***
- supported loadings,***
- non-linear possibilities,***
- case-tests implementing modeling.***

***This modeling corresponds to element SHB8-PS (developed by Alain Combescure, S. Baguet, INSA LYON) which is pressed on a mesh HEXA8. The element has 5 points of integration, distributed in the thickness.***

***It under-is integrated to have good performances. To avoid blockings the modes of hourglass are stabilized by the “Assumed strain method”. It functions into linear, nonlinear geometrical and material***

***(behavior VMIS\_ISOT\_TRAC only).***

### **3 Possibilities** **non-linear**

#### **3.1** **Law of behavior**

**The law of behavior available under COMP\_INCR in STAT\_NON\_LINE is defined by the relation VMIS\_ISOT\_TRAC (cf [U4.51.11]).**

#### **3.2 Deformations**

**Deformations available, used in the relations of behavior under the key word DEFORMATION in STAT\_NON\_LINE are (cf [U4.51.11]):**

**/“SMALL”**

**The deformations used for the relation of behavior are the deformations linearized.**

**/“GREEN”**

**The deformations used in the relation of behavior are the deformations of GREEN\_LAGRANGE.**

### **4** **Examples of implementation: case-tests**

- Linear Statique**  
**SSLS124A [V3.03.124]: Quasi-static analysis of a beam in inflection, embedded with one end and subjected to a vertical force at the other end.**
- Non-linear Statique**  
**SSNS101A [V6.05.101]: Analyze static non-linear geometrical (breakdown) of a panel cylindrical under a specific force.**
- Linear Dynamique**  
**SDLS109H [V2.03.109]: Seek Eigen frequencies and modes associated with a ring cylindrical thick.**

### **· VITE\_FACE**

Allows to specify the field normal speed real, vibratory imposed in loading on elements of border.

Supported modelings: **2D\_FLUIDE**, **AXIS\_FLUIDE**

### **· IMPE\_FACE**

Allows to specify the chart of normal impedance imposed in boundary condition on elements of border.

Supported modelings: **2D\_FLUIDE**, **AXIS\_FLUIDE**

### **· ONDE\_FLUI**

Allows to specify an amplitude of pressure of sinusoidal real incidental wave arriving normally with a face.

Supported modelings: **2D\_FLUIDE**, **AXIS\_FLUIDE**

## **3 Possibilities non-linear**

### **3.1**

#### **Laws of behaviors**

The only relation of behavior available in **DYNA\_NON\_LINE**, for modelings **2D\_FLUI\_STRU** and **AXIS\_FLUI\_STRU** under **COMP\_INCR** are **RELATION "ELAS"** (cf [U4.51.11]).

## 3.2 Deformations

*Only the linearized deformations “SMALL” key word under DEFORMATION are available in relations of behavior (cf [U4.51.11]).*

4

*Examples of implementation: case-tests*

· *2D\_FLUIDE*

*FDLV111B [V8.01.111]: Calculation of the absorption of a wave of pressure created by a piston, in a fluid column.*

· *AXIS\_FLUIDE*

*AHLV101C [V8.22.101]: Calculation of the acoustic field of pressure of the harmonic response of one guide rectilinear wave at anechoic exit, with rigid walls, whose propagation medium is of “normal” air, excited by a harmonically vibrating piston.*

· *2D\_FLUI\_STRU*

*FDLV111B [V8.01.111]: Calculation of the absorption of a wave of pressure created by a piston, in a fluid column.*

· *AXIS\_FLUI\_STRU*

*ADLV100C [V8.21.100]: Piston coupled to a fluid column: calculation in fluid coupling acoustics-structure of the first mode of a system fluide1 - piston fluid 2.*

***Modelings AXIS\_SI, D\_PLAN\_SI, C\_PLAN\_SI***

***Summary:***

***Modelings AXIS\_SI, D\_PLAN\_SI, C\_PLAN\_SI (Phenomenon: MECHANICS) correspond to finite elements whose meshes supports are surface.***

**The suffix *\_SI* means: Under - Integrated: the integration of the terms relating to the laws of behavior is done**

**reduced way (diagram of points of Gauss of a nature less low than modeling with complete integration).**

**The assumptions of modeling are as follows:**

- **AXIS\_SI for the axisymetry (mode 0 of Fourier) according to the y axis,**
- **D\_PLAN\_SI for the plane deformations,**
- **C\_PLAN\_SI for the plane constraints.**

**This document describes for modelings:**

- **degrees of freedom carried by the finite elements which support modeling,**
- **the related meshes supports,**
- **supported loadings,**
- **nonlinear possibilities,**
- **case-tests implementing modelings.**

**Modelings** *AXIS\_INCO, D\_PLAN\_INCO*

***Summary:***

***This document describes for modelings AXIS\_INCO, D\_PLAN\_INCO:***

- degrees of freedom carried by the finite elements which support modeling,***
- the related meshes supports,***
- supported loadings,***
- non-linear possibilities,***
- case-tests implementing modelings.***

***This modeling is based on finite elements adapted to the treatment of the problems quasi-incompressible. It is essential to carry out calculations of limiting analysis with the law of Norton-***

***Hoff and is also useful for the studies presenting of strong plastic deformations for which traditional formulation in displacement appears insufficient (oscillation of the constraints). The formulation used***

***is a formulation with 3 fields: displacement-pressure-swelling [R6.03.05], usable with all them behaviors written in incremental form. Modelings are supported by plane meshes of degree 2 (TRIA6 and QUAD8).***

### **3 Possibilities**

#### ***non-linear***

***Attention, this modeling is accessible only starting from STAT\_NON\_LINE. It cannot be used with MECA\_STATIQUE or by a manual assembly.***

#### **3.1**

##### ***Laws of behaviors***

***All the laws of behavior usable on meshes of continuous mediums have a physical direction for these modelings and are easily affected as from the moment when they are accessible from COMP\_INCR in STAT\_NON\_LINE (cf [U4.51.11]).***

***A law of behavior is specific to this modeling (dedicated to the calculation of limiting load, cf [R7.07.01]):***

***/“NORTON\_HOFF”***

***Supported modelings: D\_PLAN\_INCO, AXIS\_INCO***

#### **3.2 Deformations**

***Deformations available, used in the relations of behavior under the key word DEFORMATION for operators STAT\_NON\_LINE and DYNA\_NON\_LINE are (cf [U4.51.11]):***

***/“SMALL”***

***The deformations used for the relation of behavior are the deformations linearized.***

***/“SIMO\_MIEHE”***

***Allows to carry out calculations in great plastic deformations.***

#### **3.3**

##### ***Method of Newton***

***For the resolution of the problem by the method of Newton-Raphson, the elastic matrix is not available. It is thus necessary to use under the key word NEWTON for operators STAT\_NON\_LINE and DYNA\_NON\_LINE (cf [U4.51.11]):***

***/PREDICTION = “TANGENT”***

*The phase of prediction is carried out with the tangent matrix.*

*/MATRIX = "TANGENT"*

*The matrix used for the iterations total is the tangent matrix.*

*Note:*

*The formulation used leads to nonpositive matrices and the current solveurs do not know to solve always well the linear systems which are associated for them. In the event of difficulty of convergence, it can thus be useful to test the other solveurs available in the code or them other methods of renumérotations (cf [U4.50.01]).*

***J.M. PROIX, F. LEBOUVIER Key***

***:***

***U3.13.09-C Page***

***: 3/4***

***3 Loadings***

***supported***

***The supported loading is as follows:***

### ***· “GRAVITY”***

***Allows to apply a loading of the gravity type.  
Supported modelings: 2D\_DIS\_T, 2D\_DIS\_TR***

## ***Possibilities not - linear***

***Only modeling 2D\_DIS\_T being pressed on a mesh with 2 nodes is usable with STAT\_NON\_LINE and DYNA\_NON\_LINE. It is only in this case that one uses DEFI\_MATERIAU.***

### ***4.1***

#### ***Law of behavior***

***Laws of behaviors specific to these modelings, usable under COMP\_INCR in STAT\_NON\_LINE and DYNA\_NON\_LINE the following ones (cf [U4.51.11]):***

***/“DIS\_GOUJ2E\_ELAS”***

***Supported modeling: 2D\_DIS\_T (Mesh SEG2)***

***/“DIS\_GOUJ2E\_PLAS”***

***Supported modeling: 2D\_DIS\_T (Mesh SEG2)***

***/“ELAS”***

***Supported modelings: 2D\_DIS\_T, 2D\_DIS\_TR***

***In addition to the assignment of characteristics (AFFE\_CARA\_ELEM) the use of modelings DIS\_T and DIS\_TR with STAT\_NON\_LINE/DYNA\_NON\_LINE/DYNA\_TRAN\_EXPLI implies to define characteristics material (AFFE\_MATERIAU).***

### ***4.2 Deformations***

***Deformations available, used in the relations of behavior under the key word DEFORMATION for operators STAT\_NON\_LINE and DYNA\_NON\_LINE are (cf [U4.51.11]):***

***/“SMALL”***

***The deformations used for the relation of behavior are the linearized deformations calculated on the initial geometry.***

***Supported modeling: 2D\_DIS\_TR (Mesh SEG2)***

***/“PETIT\_REAC”***

***The deformations used in the incremental relation of behavior are the deformations linearized calculated on the reactualized geometry.***

## ***Modeling 2D\_FLUI\_ABSO***

### ***Summary:***

***This document describes for modeling 2D\_FLUI\_ABSO:***

- degrees of freedom carried by the finite elements which support modeling,***
- the related meshes supports,***
- supported loadings,***
- nonlinear possibilities,***
- case-tests implementing modeling.***

***Modeling 2D\_FLUI\_ABSO (Phenomenon: MECHANICS) corresponds to finite elements of which meshes supports are linear. They make it possible to take into account the condition of absorbing border of sections fluid volumes, moving plane.***

## **2 Loadings supported**

*The loadings available are as follows:*

### **· “CONTACT”**

*Allows to define the zones subjected to conditions of contact.*

*Supported modelings: 3D, 3D\_SI*

### **· “FORCE\_ARETE”**

*Allows to apply linear forces, with an edge of voluminal element.*

*Supported modelings: 3D, 3D\_SI*

### **· “FORCE\_FACE”**

*Allows to apply surface forces to a voluminal face of element.*

*Supported modelings: 3D, 3D\_SI*

### **· “FORCE\_INTERNE”**

*Allows to apply voluminal forces.*

*Supported modelings: 3D, 3D\_SI*

### **· “GRAVITY”**

*Allows to apply a loading of the gravity type.*

*Supported modelings: 3D, 3D\_SI*

### **· “PRES\_REP”**

*Allows to apply a pressure to a field of continuous medium.*

*Supported modelings: 3D, 3D\_SI*

### **· “TEMP\_CALCULEE”**

*Allows to apply a thermal loading.*

*Supported modelings: 3D, 3D\_SI*

### **· “SECH\_CALCULEE”**

*Allows to apply a field of drying.*

*Supported modelings: 3D, 3D\_SI*

### **· “HYDR\_CALCULEE”**

*Allows to apply a field of hydration and a field of temperature.*

*Supported modelings: 3D, 3D\_SI*

· **“EPSA\_CALCULEE”**

*Allows to apply a field of anelastic deformations resulting from external software.*

*Supported modelings: 3D, 3D\_SI*

· **“PRES\_CALCULEE”**

*Allows to apply a field of pressure resulting from external software.*

*Supported modelings: 3D, 3D\_SI*

*: 4/4*

· **“EPSI\_INIT”**

*Allows to apply a field of initial deformation.*

*Supported modelings: 3D, 3D\_SI*

· **“ROTATION”**

*Allows to apply a number of revolutions and a vector of rotation.*

*Supported modelings: 3D, 3D\_SI*

· **“EFFE\_FOND”**

*Allows to calculate and apply the basic effect on a branch of piping subjected to one internal pressure.*

*Supported modelings: 3D, 3D\_SI*

**3 Possibilities**

***non-linear***

### **3.1**

#### ***Laws of behaviors***

*Laws of behaviors (model traditional, model buildings with damage, models for the concrete and the grounds,...), usable under COMP\_INCR or COMP\_ELAS in STAT\_NON\_LINE and DYNA\_NON\_LINE, under the key word RELATION, are described in details in the document “Behavior nonlinear” [U4.51.11].*

### **3.2 Deformations**

*Deformations usable under COMP\_INCR or COMP\_ELAS in STAT\_NON\_LINE and DYNA\_NON\_LINE, under the key word DEFORMATION, are described in details in the document “Behavior nonlinear” [U4.51.11].*

## **4**

### ***Examples of implementation: case-tests***

#### **· 3D**

*Statics*

*linear*

*FORMA01C [V7.15.100]: Quasi-static analysis of a piping comprising an elbow subjected to a specific force, an internal pressure and a thermal transient.*

*Statics*

*non-linear*

*HSNV121A: [V7.15.121]: Quasi-static analysis in great deformations of a bar under thermal loading subjected to a force of traction.*

*Dynamics*

*linear*

*SDLV100A [V2.04.100]: Seek frequencies and modes of inflection associated with one slim beam of variable rectangular section (embed-free).*

*Dynamics*

*non-linear*

*SDNV100A [V5.03.100]: Analyze transitory direct of a slim beam animated of one initial speed coming to run up against a rigid wall.*

#### **· 3D\_SI**

*Statics*

*non-linear*

*HSNV125D: Quasi-static analysis of a volume in traction subjected to a temperature variable and with a loading in shearing with a law of viscoplastic behavior (case-test n°2 PHI2AS “non-linear Behavior of materials”, 2000 Volume XXIV N°1).*

*Dynamics*

*non-linear*

*SDNV103A [V5.03.103]: Analyze impact of an elastoplastic bar of Taylor on one rigid solid mass. Modeling takes into account the contact with friction and one behavior elastoplasticity with great deformations.*

***Instruction manual***

***U3.14 booklet: Mechanical finite elements 3D***

***Document: U3.14.06***

***Modeling 3D\_INCO***

***Summary:***

*This document describes for modeling 3D\_INCO:*

- *degrees of freedom carried by the finite elements which support modeling,*
- *the related meshes supports,*
- *laws of behavior and loadings supported,*
- *non-linear possibilities,*
- *case-tests implementing modeling.*

*This modeling is based on finite elements adapted to the treatment of the problems quasi-incompressible. It is essential to carry out calculations of limiting analysis with the law of Norton-Hoff and is also useful for the studies presenting of strong plastic deformations for which traditional formulation in displacement appears insufficient (oscillation of the constraints). The formulation used*

*is a formulation with 3 fields: displacement-pressure-swelling [R6.03.05], usable with all them behaviors written in incremental form. Modeling 3D\_INCO has voluminal meshes supports and accept the TETRA10, the HEXA20, and the PENTA15.*

**3D TRIA6**  
**Quadratic**  
**Quadratic QUAD8**

**2 Loadings**  
**supported**

*The loadings available under AFFE\_CHAR\_MECA\_ are as follows:*

· **“FORCE\_ARETE”**

*Allows to apply linear forces, with an edge of voluminal element.*

· **“FORCE\_FACE”**

*Allows to apply surface forces to a voluminal face of element.*

· **“FORCE\_INTERNE”**

*Allows to apply voluminal forces.*

· **“GRAVITY”**

*Allows to apply a loading of the gravity type.*

· **“PRES\_REP”**

*Allows to apply a pressure to a field of continuous medium.*

**:**

**U3.14.06-D Page**

**: 3/4**

**3 Possibilities**

**non-linear**

**Attention, this modeling is accessible only starting from STAT\_NON\_LINE. It cannot be used with MECA\_STATIQUE or by a manual assembly.**

**3.1**

**Laws of behavior**

*All the laws of behavior usable on meshes of continuous mediums have a physical direction for these modelings and are easily affected as from the moment when they are accessible from COMP\_INCR in STAT\_NON\_LINE (cf [U4.51.11]).*

*Let us announce that a law of behavior is specific to this modeling (dedicated to the calculation of load limit, cf [R7.07.01]):*

*/“NORTON\_HOFF”*

### *3.2 Deformations*

*Deformations available, used in the relations of behavior under the key word DEFORMATION for operators STAT\_NON\_LINE, DYNA\_NON\_LINE and DYNA\_TRANS\_EXPLI are (Cf [U4.51.11]):*

*/“SMALL”*

*The deformations used for the relation of behavior are the deformations linearized.*

*/“SIMO\_MIEHE”*

*Allows to carry out calculations in great plastic deformations.*

### *3.3*

#### *Method of Newton*

*For the resolution of the problem by the method of Newton-Raphson, the elastic matrix is not available. It is thus necessary to use under the key word NEWTON for operators STAT\_NON\_LINE and DYNA\_NON\_LINE (cf [U4.51.11]):*

*/PREDICTION = “TANGENT”*

*The phase of prediction is carried out with the tangent matrix.*

*/MATRIX = “TANGENT”*

*The matrix used for the iterations total is the tangent matrix*

*Note:*

*The formulation used leads to nonpositive matrices and the current solveurs do not know*

*to solve always well the linear systems which are associated for them. In the event of difficulty of convergence, it can thus be useful to test the other solveurs available in the code or them other methods of renumérotations (cf [U4.50.01]).*

***Instruction manual***

***U3.22 booklet: Thermal elements of structure 2D***

***U3.22.01 document***

***Modelings HULL, COQUE\_PLAN, COQUE\_AXIS -  
THERMAL phenomenon***

***Summary:***

***This document describes for thermal modelings of the axisymmetric and plane elements:***

- degrees of freedom carried by the finite elements which support modeling,***
- the related meshes supports,***
- supported loadings,***
- nonlinear possibilities,***
- case-tests implementing modelings.***

***Modeling HULL of the THERMAL Phenomenon [R3.11.01] is usable to treat the equations of heat in mediums with average layer in linear thermal analysis. One can use it like the first calculation of a thermomechanical chaining with the corresponding machine elements.***

## **1 Discretization**

### **1.1**

#### **Degrees of freedom**

**The degrees of freedom are the temperatures *TEMP* (temperature on the average surface of the hull), *TEMP\_INF* (temperature on the lower surface of the hull), and *TEMP\_SUP* (temperature on upper surface of the hull).**

### **1.2**

#### **Meshes support of the matrices of rigidity**

#### **Modeling Nets Element**

**finished**

**Remarks**

**HULL TRIA3**

**THCOTR3**

**nodes with 3 co-ordinates X, y, Z**

**TRIA6**

**THCOTR6**

**TRIA7**

**THCOTR7**

**QUAD4**

**THCOQU4**

**QUAD8**

**THCOQU8**

**QUAD9**

**THCOQU9**

**COQUE\_PLAN SEG3**

**THCPSE3 nodes with 2 co-ordinates X, y**

**COQUE\_AXIS**  
**SEG3**  
**THCASE3**

*For THCOTRI, only the 3 tops are exploited to define the local geometry (tangent plan, normal). For THCOQUI, one considers that the element is plane and its tangent plan is defined by defect by 3 of the 4 tops of the element.*

**1.3**

**Net support of the loadings**

*All the loadings applicable to the facets of the elements of hull are treated by discretization direct on the mesh support of the element in temperature formulation.*

*No mesh support of loading is thus necessary for the faces of the elements of hulls.*

*For the applicable loadings on the edges of the elements of hull or plate of modeling - hull, a mesh support of the type SEG2 or SEG3 must be used.*

**Modeling Nets Element**

**finished**

**Remarks**

*HULL SEG2*

*THCOSE2 with TRIA3 and QUAD4*

*HULL SEG3*

*THCOSE3 with TRIA6 or TRIA7 and*

*QUAD8 or QUAD9*

*For the imposed temperatures, the meshes support are meshes reduced to a point.*

**2**

**Assignment of the characteristics**

*For these elements of thermal structures, it is necessary to affect characteristics geometrical which is complementary to the data of grid. The definition of these data is carried out with order AFFE\_CARA\_ELEM associated with the key word following factor:*

**· HULL**

*Allows to define and affect the thickness on the meshes.*

### **3 Loadings supported**

*The loadings available are as follows:*

#### **· FLUX\_REP**

*Allows to apply normal flows to faces of elements of hulls to the faces  $\pm$ .*

*Supported modelings: HULL, COQUE\_PLAN, COQUE\_AXIS*

#### **· EXCHANGE**

*Allows to apply conditions of exchange with an outside temperature with faces of hulls on the faces  $\pm$ .*

*Supported modelings: HULL, COQUE\_PLAN, COQUE\_AXIS*

### **4 Possibilities**

#### **non-linear**

*Nothing.*

### **5 Possibilities**

#### **transients**

*Only modeling HULL makes it possible to deal with the evolutionary problems of thermics.*

## 6

### **Examples of implementation: case-test**

#### **· HULL**

*Stationary linear thermics*

*HPLA100C [V7.01.100]: Analyze of a heavy thermoelastic hollow roll in rotation uniform. In this modeling, one carries out a chained thermoelastic calculation and a calculation thermoelastoplastic without plastic evolution.*

*TPLS100A [V4.03.100]: Analyze thermal in stationary regime of an infinite plate subjected to a couple of antisymmetric heat flows on its two half-faces.*

*Transitory linear thermics*

*TTLL01M [V4.21.001]: Analyze thermal linear transient of an infinite wall subjected to a shock thermics.*

#### **· COQUE\_PLAN**

*Stationary linear thermics*

*HPLA100B [V7.01.100]: Analyze of a heavy thermoelastic hollow roll in rotation uniform. In this modeling, one carries out a chained thermoelastic calculation and a calculation thermoelastoplastic without plastic evolution.*

*TPLS100B [V4.03.100]: Analyze thermal in stationary regime of an infinite plate subjected to a couple of antisymmetric heat flows on its two half-faces.*

**· GRAD\_TEMP\_EPSI**

*Allows to apply a presumed uniform variation in temperature “initial” in the element.*

*Supported modelings: AXIS (\_DIAG), PLAN (\_DIAG)*

**· CONVECTION**

*Allows to take into account the terms of transport of heat by convection, for*

*THER\_NON\_LINE\_MO only.*

*Supported modelings: AXIS, PLAN*

**· RADIATION**

*Allows to take into account ad infinitum radiated flow.*

*Supported modelings: AXIS (\_DIAG), PLAN (\_DIAG)*

**3 Possibilities**

**non-linear**

**Two operators are available for the study of non-linear behaviors:**

**· THER\_NON\_LINE [U4.54.02]:** *this operator allows, in hover or in transient, of to solve the problems of:*

*Standard non-linear thermics: material depend on the temperature, conditions with limits (radiation and nonlinear imposed flow),*

*Non-linear thermics with calculation of the hydration of the concrete,*

*Drying of the concrete.*

**· THER\_NON\_LINE\_MO [U4.54.03]:** *this operator allows to solve the equation of heat*

*stationary in a mobile reference frame related to a loading and moving in a direction and at a given speed.*

## **4**

*Examples of implementation: case-tests*

### **4.1 Thermics**

#### **· AXIS**

*Stationary linear thermics*

*TPLA07A [V4.01.007]: Analyze thermal of an orthotropic hollow roll subjected to different boundary conditions (imposed flow, convection, linear variation of the temperatures external).*

*Stationary non-linear thermics*

*TPNA01A [V4.41.001]: Analyze thermal of a hollow roll subjected to a convectif exchange on the interior wall and with a radiation ad infinitum on the external wall.*

*Transitory linear thermics*

*TTLV01B [V4.25.001]: Analyze thermal linear transient of a full sphere subjected to a heat transfer by convection.*

*Transitory non-linear thermics*

*TTNA200A: case-test of not-regression*

#### **· PLANE**

*Stationary linear thermics*

*TPLL100B [V4.02.100]: Analyze thermal of an anisotropic plane wall subjected to one temperature imposed and on a flow.*

*Stationary non-linear thermics*

*TPNL300A [V4.42.300]: Analyze thermal unidimensional of a wall subjected to one temperature imposed on the internal wall and on an exchange by radiation on the wall external (Test NAFEMS).*

**2 Loadings**  
**supported**

**The loadings available are as follows:**

- **SOURCE**  
**Allows to apply voluminal sources to a field 3D.**  
**Supported modelings: 3D, 3D\_DIAG**
- **FLUX\_REP**  
**Allows to apply normal flows to faces of voluminal elements.**  
**Supported modelings: 3D, 3D\_DIAG**
- **EXCHANGE**  
**Allows to apply conditions of exchange with an outside temperature with faces voluminal elements.**  
**Supported modelings: 3D, 3D\_DIAG**
- **ECHANGE\_PAROI**

*Allows to apply conditions of exchange between two walls.*

*Supported modelings: 3D, 3D\_DIAG*

*· GRAD\_TEMP\_INIT*

*Allows to impose a presumed uniform variation in temperature in an element*

*Supported modelings: 3D, 3D\_DIAG*

*· CONVECTION*

*Allows to take into account the terms of transport of heat by convection, for THER\_NON\_LINE\_MO only.*

*Supported modeling: 3D*

*· RADIATION*

*Allows to take into account the flow radiated ad infinitum with faces of voluminal elements*

*Supported modelings: 3D, 3D\_DIAG*

### *3 Possibilities*

*non-linear*

*Two operators are available for the study of non-linear behaviors:*

*· THER\_NON\_LINE [U4.54.02]: this operator allows, in hover or in transient, of to solve the problems of:*

*Standard non-linear thermics: material depend on the temperature, conditions with limits (radiation and nonlinear imposed flow),*

*Nonlinear thermics with calculation of the hydration of the concrete,*

*Drying of the concrete.*

*· THER\_NON\_LINE\_MO [U4.54.03]: this operator allows to solve the equation of heat stationary in a mobile reference frame related to a loading and moving in a direction and at a given speed.*

**Recalls on the syntax of the orders Aster**

**The process control language and its supervisor are completely described in the document [U1.03.01]. One recalls here some notions on syntax of the Aster orders.**

**In Aster, one understands by the generic term of orders at the same time the operators, them procedures and macro-orders of the process control language. An operator provides a concept product typified (by the operator) and named by the user. A procedure does not generate a concept product, it achieves actions such as impressions or resource allocations.**

*In the example below, one recalls the vocabulary which is used in the description of orders.*

*Operand (S) or body of the order*  
*Character of end of assignment*

*obligatory*

*Name chosen by the user*

*Operand*  
*Operand*

*Operand*

*bet0 = DEFI\_MATERIAU (ELAS = \_F (E = 3.4E10, NAKED = 0.25, RHO = 2500.) );*

*Produced concept*  
*Name of Word-key-factor*  
*Key word*  
*Argument*  
*End of order*

*the operator*  
*(optional)*

*Terminology Aster*

*An operand is thus the unit consisted a key word and its argument. However, in documentation of the orders, one often indicates the operands of an operator or one procedure by the name of their key word. For example: RHO, single-ended spanner word, or ELAS, key word factor.*

*The term of produced concept is generic for all the operators, it is the result of the work of*

*the operator.*

*Here in example `DEFI_MATERIAU`, there was creation of the structure of data of the `MATER` type (material), named `concrete` by the user. It gathers the denominations (key word `E`, `NAKED`, `RHO`) and the values (arguments `3.4E10`, `0.25`, `2500.`) mechanical elastic characteristics (key word factor `ELAS`) of material.*

*The term of concept-product of the result type is reserved to the operators of end of calculation of one modeling Aster. In general, these operators provide the result of calculation, i.e. physical fields of sizes (displacements, temperatures, constraints, efforts, etc...) on nodes or on the meshes at various moments or for various frequencies.*

*The concept result comprises in general under types.*

**2**

*Standard plan of the documents of use of the orders*

*Each document of presentation of an order comprises the following chapters:*

- .  
*Drank,*
- .  
*Syntax,*
- .  
*Operands,*
- .  
*Phase of checking/Production run (possibly),*
- .  
*Examples.*

*This presentation makes it possible the user to find in only one document all knowledge necessary to the implementation of an order.*

*Instruction manual*

*U4.0 booklet: Use of the orders*

*HT-66/05/004/A*

**Author (S):**

**COURTEOUS Mr., F. WAECKEL, Key Mr. BOIN**

**:**

**U4.01.00-E Page**

**: 4/12**

### **3 Paragraph**

**Drank**

*One states the functionality filled by the order (actions carried out). They are also specified types of the concepts awaited in entry and the produced concept, as well as characteristics of order. The first sentence of this paragraph is also posted automatically in so much what bars information by Efficas.*

*This paragraph is also posted by the search engines; it thus contains only text without equations or formula.*

*Example: Operator STAT\_NON\_LINE [U4.51.03]*

**Drank:**

*To calculate the quasi-static mechanical evolution of a structure into nonlinear.*

*Nonthe linearity is related either to the behavior of material (for example plastic), or with geometry (for example in great displacements). To have details on the method of resolution employed, one will refer to the reference material [R5.03.01].*

*The evolution can be studied in several successive work (réentrant concept), that is to say in continuation (the last calculated moment is the initial moment of following calculation), is in recovery in on the basis of one former moment.*

*If time necessary to carry out calculation is not sufficient, the program stops, but the already calculated results are safeguarded if a data base were defined in profile of study of the user. Product a structure of data of the evol\_noli type.*

### **4 Paragraph**

**Syntax**

*One gives, in this paragraph, the whole of the operands of the order. One specifies, for each operand, using méta-characters and of indentations suitable for the typographical presentation of orders (cf example of operator AFFE\_MATERIAU):*

- 
- the name of the operator,*
- 
- the name of the key words,*
- 
- the reference symbols user of the produced concept and the arguments of the key words,*
- 
- obligatory or optional character of the operands (statute),*
- 
- alternatives in the choices of the operands,*
- 
- types of the arguments awaited by the key words,*
- 
- default values taken by the arguments in the case of optional operands,*
- 
- the type of the produced concept, when it is about an operator.*

*Reference symbol of*  
*Type of*

*Name of the operator*  
*Produced concept*  
*Produced concept*  
*Name*

*symbolic system of*

*chm [*  
*cham\_mater] = AFFE\_MATERIAU*  
*the argument*

*(*  
*GRID = my,*

*[grid]*  
*Argument*

*imposed of type*  
*AFFE = \_F (*

*/TOUT= "YES",*

## **U4.01.00-E Page**

**: 5/12**

### **4.1**

#### ***Méta-characters of statute of operands (/)***

***Four méta-characters are used to indicate the statute of the operands. It is necessary to understand here by statute of the operands their obligatory or optional declaration and the nature of the alternatives in choice of the operands.***

***These méta-characters do not form part of the process control language. They have only one function of documentary presentation and should not thus be used for the drafting of the file of orders.***

#### **4.1.1 Obligatory or optional operands**

***They are located by the presence at the head black or white rhombus.***

***black rhombus: it is obligatory to declare in the order the operands which follow it sign.***

***white rhombus: the declaration of the operands which follow this sign is optional. In case of absence of the operand, the order will affect possibly one or of the default values.***

***Example: operator `DEFI_LIST_ENTI`  
(definition of a list of strictly increasing entirities  
whose values are regularly spaced)***

***Li  
= `DEFI_LIST_ENTI`  
(***

***BEGINNING***

***=***

***deb.***

***,***

***INTERVAL = \_F (JUSQU\_A = yew,***

***NOT***

***=***

***ipas,***

***)***

***);***

***.***

***It is obligatory to declare the operand identified by the key word BEGINNING and to provide deb. which is the first entirety of the list to be built.***

***.***

***It is not obligatory to declare the operand identified by the key word factor INTERVAL. In this case the list of entireties will be summarized with only one entirety of value deb. (this is specified in the description of the operands).***

.  
*If the operand INTERVAL is declared, then it is obligatory to declare the operand JUSQU\_A which specifies the whole end yew of the interval to be cut out with a constant step and the operand NOT which indicates the step ipas interval division.*

#### *4.1.2 Alternatives in the choice of the operands*

*They are located by the presence at the head each choice of the alternative:*

.  
*of one/(slash): exclusive alternative, only one choice among those proposed,*

.  
*of one | (pipe, semi colonist): nonexclusive alternative, one or more choice among those proposed.*

**In this operator, it is necessary to specify obligatorily:**

**.**  
**the applicability on the grid: everywhere (ALL), on certain nodes (NODE) or on certain groups of nodes (GROUP\_NO),**

**.**  
**on which degrees of freedom with which specified values by the user.**

**The méta-character | indicates that the user can impose a value of displacement on one (it symbol indicates that one needs at least one of them) or several of the degrees of freedom (DX, DY, DZ, DRX, DRY, DRZ, GRX, NEAR, PHI, TEMP, PRE1, PRE2) of the beforehand indicated nodes.**

#### **4.1.3 Combinations of the méta-characters of choice of the operands**

**These méta-characters can be combined to illustrate the multiplicity of the choices in some orders.**

**Example: order DEFI\_MATERIAU (definition of a material by its properties of behavior)**

**For a study of thermomechanics, one needs to define a material at the same time having mechanical characteristics (ELAS) and thermics (THER) from where use of the pipe: |**

*But in each choice, one is obliged to choose if the properties of material are dependent ( $\_FO$ ) or not of the temperature from where use of the slash: /; cf below:*

*my = DEFINI\_MATERIAU*

*(  
//ELAS =  $\_F$  (  
E =*

*yg,*

*NAKED  
= naked,*

*RHO  
=  
rho,*

***ALPHA***  
***= dil,***

)  
.....

**:**  
**U4.01.00-E Page**  
**: 8/12**

**4.2**  
**Méta-characters of the type of concept or argument**

**Like the méta-characters of statutes of operands, the hooks [] and the star \* do not form part of process control language. They have only one function of documentary presentation.**

**4.2.1 Types of concepts or arguments []**

**They frame the type of the concepts produced as well as the type of the arguments.**

**Example: order AFFE\_MODELE (Assignment of the finite elements on the meshes of a grid)**

**Mo [model] = AFFE\_MODELE**  
**(**  
**GRID =**  
**my,**

**[grid]**

***AF FE = \_F (/ALL =  
“YES”,***

***/  
NET = email,  
[l\_maille]  
.....***

***);***

***In the example above, one thus specifies that the concept produced by AF FE \_MODELE is of type model and that the awaited concept as argument of the key word MESH must be of l\_maille type (i.e list of mesh).***

#### ***4.2.2 Type of the produced concept [\*]***

***This mé ta-character indicates that the type of the produced concept, or under type of the produced concept of type result, depends on the types of the arguments of certain operands. In this case the various ones possibilities are registered after the syntax of the order.***

***Example: order COMB \_CHAM \_NO***

***In this example, if CH is a cham \_no \_DEPL \_R given in argument of key word CHAM \_NO under key word factor COMB \_C then cchno will be a cham \_no \_DEPL \_C. If, on the other hand, CH is given under key word factor COMB \_R then cchno will be a cham \_no \_DEPL \_R.***

*cchno [cham\_no\_\*] = COMB\_CHAM\_NO*

*(/COMB\_R = \_F (  
CHAM\_NO = CH,  
[cham\_no\_DEPL\_R]  
[cham\_no\_TEMP\_R]  
[cham\_no\_PRES\_R]*

*COEF\_R  
=  
R,  
[R]*

*)  
/  
COMB\_C

)

#### 4.4 *Types of the arguments awaited by the key words*

*The key words of the operands await arguments which correspond, in general, to four classes:*

- .  
*values, one then specifies by a reference symbol the accepted data-processing type (real, entirety, character string, etc...),*
- .  
*imposed texts, then the texts (“YES”, “HY1”) are indicated between quotes,*
- .  
*names of topological entities simple (name of node, meshes, or lists of names), declared in the file of grid, or the names of groups of nodes or meshes, or lists of names of groups of nodes or meshes,*
- .  
*names and lists of names of concepts produced by the operators.*

*The table below gathers all the principal types of the arguments awaited by the key words:*

[R] real  
3.  
[l\_R]  
list realities  
(1., 3., 7.)  
[I]

**automatic checking of the type**

**[l\_type\_concept] list of the type of concept user**

**(resu1, resu2)**

**4.5**

**Types of the concepts produced in Aster**

**One uses the méta-character of choice of exclusive alternative/to mean the plurality of concept waited behind a key word.**

**Example: operator ASSE\_MATRICE**

**(assembly of the elementary matrices contained**

**in a list of concepts of the matr\_elem\_\* type.)**

**my [matr\_asse\_\*] = ASSE\_MATRICE**

```
(  
MATR_ELEM  
=  
lme1,  
/  
[l_matr_elem_DEPL_R]  
  
/  
[l_matr_elem_DEPL_C]  
  
/  
[l_matr_elem_TEMP_R]  
  
/  
[l_matr_elem_TEMP_C]  
/  
[l_matr_elem_PRES_R]  
/  
[l_matr_elem_PRES_C]  
...  
  
);
```

```
if MATR_ELEM  
[matr_elem_DEPL_R]  
then [*]
```

```
DEPL_R  
[matr_elem_DEPL_C]
```

```
DEPL_C  
[matr_elem_TEMP_R]
```

**TEMP\_R**  
**[matr\_elem\_TEMP\_C]**

**TEMP\_C**  
**[matr\_elem\_PRES\_R]**

**PRES\_R**  
**[matr\_elem\_PRES\_C]**

**PRES\_C**

***In the example above the concept awaited in argument of MATR\_ELEM can be various types and on the type of the last concept in argument by the user will depend (according to stated rules' above) the typing of the concept produced by operator ASSE\_MATRICE.***

: 11/12

## **5 Paragraph**

### **Operands**

*One describes, for each operand the direction of the operand for this order, the nature and the type of arguments awaited by the key words, and the restrictions and difficulties of employment.*

*For example, in the documentation of operator AFFE\_MATERIAU, for operand AFFE, operand intended to specify on which (S) entity (S) topological (S) of the grid of name my will be affected the material of name chechmate produced by operator DEFI\_MATERIAU, one will read:*

**AFFE**

*Key word factor which makes it possible to affect various materials on “pieces” of the grid.*

**/ALL: “YES”,**

*This key word makes it possible to affect on all the meshes of the grid.*

**/GROUP\_MA: l<sub>g</sub>ma,**

*This key word makes it possible to affect on a list of groups of meshes of the grid.*

**/**

**NET**

:

**l<sub>ma</sub>,**

*This key word makes it possible to affect on a list of meshes of the grid.*

*With each group of meshes, (key word `GROUP_MA`) or each list of meshes (key word `NETS`), or still with all the grid (key word `ALL`) is affected a material chechmate, which is a produced concept by one of operators `DEFI_MATERIAU [U4.43.01]` or `DEFI_COQU_MULT [U4.42.03]`.*

*If a mesh appears explicitly (or implicitly) in several occurrences of the key word factor `AFFE`, the rule of overload is applied: it is the last assignment which precedes [U2.01.08].*

## **6** **Phases of checking/execution**

*The Syntaxe paragraph of the documentation of use is the exact reflection of the catalogue of order. This catalogue is a file which includes/understands, written in the language of the supervisor, all rules on the key words: presence, exclusion, implication, contained...*

*Editor `EFICAS` exploits this catalogue of order and allows the user, if with final the file composed is valid, to obtain a correct command set.*

*With the execution of the study, the supervisor of `Code_Aster` reproduces the same task of checking syntactic: either overall for all the file, or while alternating with the execution, orders by order.*

*Moreover, during the execution itself of the orders (entered part `FORTTRAN` of source code), of the additional checks can be made. They are impossible constraints to manage on the level of the process control language (equality of cardinals of different lists...).*

*Instruction manual*

## **7** ***Print and indentations***

*For the legibility of the documents relating to the orders, all that refers to syntax is printed in police force Courier 10 points. One differentiates the various types of functional elements (produced concept, key word, key word factor, argument) by the use of capital letters and tiny.*

*In capital letters:*

- .  
*names of the operators, the procedures*
- .  
*names of the key words and the key words factors,*
- .  
*imposed arguments of type text (those are between “quotes” as in the syntax of orders).*

*In small letters:*

- .  
*names of the produced concepts,*
- .  
*reference symbols of the arguments,*
- .  
*types of the produced concepts and the arguments.*

*Into mixed tiny - capital letter when the produced concept admits under type. This one appears in capital letters as well as type FORTRAN of the size of under type.*

*One reinforces the legibility of syntax by the use of indentations. They are used for the location of the blocks*

*operands and with the release of a group of operands under a key word factor. They too are used to lay out the brackets of the same block under the same balance.*

*Example:*

*my [matr\_asse\_\*] = ASSE\_MATRICE*

*(  
MATR\_ELEM  
=*

*lme1,*

/

*[l\_matr\_elem\_DEPL\_R]*

## **1**

***Innovations between 7.3 and 7.4***

### **1.1**

***Modifications of the environment***

#### **1.1.1 Med**

***Code\_Aster is pressed now on library MED 2.2. For reading files with the format med 2.1.5, they should be converted with the tool med\_import (there are not tools in the opposite direction).***

#### **1.1.2 Lobster**

***Following the change of version of med, lobster also evolved/moved to support the same level of library. lobster 7.1 also brings other innovations (cf [U7.03.xx]).***

### **1.2 News**

***orders***

#### **1.2.1 CREA\_TABLE**

***This order makes it possible to create a table starting from a function or several lists of entirities, of realities or of character strings. One can create a full table or with holes by indicating the lines that one wishes to inform.***

#### **1.2.2 DEFI\_COMPOR**

***This order makes it possible to define a single-crystal or polycrystalline behavior.***

#### **1.2.3 DEFI\_PART\_FETI**

*This order makes it possible to create a partitioning in under-fields for a resolution by Feti method.*

#### **1.2.4 IMPR\_FONCTION**

*This new order replaces IMPR\_COURBE, and it treats only the functions (from where it renaming), tables being treated by IMPR\_TABLE (cf [7.3.13]).*

#### **1.2.5 MACR\_ECLA\_PG**

*This macro-order replace options ECLA\_PG of two orders CREA\_MAILLAGE and CREA\_RESU. Coherence between the two orders is thus ensured.*

#### **1.2.6 MODI\_MODELE\_XFEM**

*This order makes it possible to create finite elements with ddl nouveau riches necessary to the method XFEM.*

### **1.3 Orders reabsorbed**

#### **1.3.1 DEFI\_VALEUR**

*Contents of the Python objects being safeguarded (in the file pick.1) “at side” of the base Aster (file glob.1), it is not necessary any more to have a specific order to define a parameter.*

*For example (see also [U3.01.0x]):*

*deuxpi = 2.\*pi*

#### **1.3.2 IMPR\_COURBE**

*Replaced by IMPR\_FONCTION (cf [7.3.13]).*

#### **1.3.3 POST\_GOUJ2E**

*This order had not been reabsorbed at the same time as the associated macros MACR\_GOUJ2E\_MAIL/CALC. The method for calculation is preserved in the case-tests zzzz120a and zzzz120b (cf [7.2.14]).*

***:***

***U4.01.03-A Page***

***: 3/22***

***1.4***

***Modifications common to several orders***

***1.4.1 Key words***

***FILE and UNIT***

***According to the type of order, one was to use is UNIT (reading commands) where one was awaited logical number of unit, is FILE (orders of postprocessing) behind which one waited not not a file name but a “label” (ddname) which was associated a logical unit by defect or affected via order DEFI\_FICHER (ex-DEFUFI).***

***The concept of label disappears; the orders function all with UNIT and, those which know to use a true file name also the key word FILE accepts.***

***The risk of confusion is reduced: one provides to UNIT the logical unit well informed in astk and to FILE a file name complete Unix (see also the use of REPE\_IN/REPE\_OUT in documentation of astk [U1.04.00]).***

***1.4.2 Orders of postprocessing CALC\_ELEM, CALC\_NO, CALC\_G\_LOCAL\_T, CALC\_G\_THETA\_T, POST\_ELEM***

***MODEL, CHAM\_MATER, CARA\_ELEM, EXCIT become optional:***

***· The structure of data result (exit of STAT\_NON\_LINE, THER\_LINEAIRE...) keep in memory these 4 parameters, it thus becomes optional to provide them to these operators post-treatments. One can however inform these key words in certain particular cases; one check whereas they are the same ones which was used for calculation, if it is not the case, one emits an alarm or one stops in error (case of the MODEL) (cf [7.3.7], [7.3.24]).***

***1.5 Orders***

***modified***

***1.5.1 AFFE\_CARA\_ELEM***

**ANGL\_L, POUR\_CENT\_L, POUR\_CENT\_T removed, famous SECTION\_L in SECTION:**  
· *These key words do not have any more interest since the introduction of new elements of grid membrane which makes it possible to model the grids of reinforcement in a given direction, and who are usable jointly with a modeling 3D of the concrete. In the same way elements roast (usable with “hull” work from now on in only one direction. Orientation reinforcements is defined under ANGL\_REP (cf [7.3.10]).*

**Modified POUTRE/VARI\_SECT:**

· *To guide the user among the possible choices, one chooses a value now for SECTION, then for VARI\_SECT (new choice: CONSTANT by defect) what allows to limit the list of possible for CARA (cf [7.3.23]).*

**PREC\_AIRE, PREC\_INERTIE new:**

· *One checks the coherence of the information (surface and inertia of the multifibre beams) provided under key words BEAM and AFFE\_SECT with the precision indicated by these key words (cf [7.3.28]).*

**1.5.2 AFFE\_CHAR\_MECA/AFFE\_CHAR\_MECA\_F**

**FORMULATION new:**

· *At the time of the resolution of a problem of contact with the method continues, one has the choice enters a formulation in displacement (value DEPL) or of speed (value QUICKLY, well adapted numerically with the treatment of the shocks) (cf [7.3.18]).*

**TOLE\_PROJ replaced by TOLE\_PROJ\_EXT, new TOLE\_PROJ\_INT:**

· *In the case of symmetrical pairing MAIT\_ESCL\_SYME, it is necessary to lay out of a tolerance of projection for the detection of the null pivots (cf [7.3.23]).*

**New ITER\_MULT\_MAXI:**

· *ITER\_MULT\_MAXI multiplied by the number of nodes slaves gives the maximum number iterations of contact (cf [7.3.23]).*

:

U4.01.03-A Page

: 4/22

**COEF\_MULT\_2,**

**VECT\_NORM\_2,**

**DIST\_1,**

**DIST\_2 replaced by COEF\_MULT\_ESCL,**

**VECT\_NORM\_ESCL, DIST\_MAIT and DIST\_ESCL:**

· Homogénéisation of the vocabulary following the renaming of GROUP\_MA\_1/2 in GROUP\_MA\_MAIT/ESCL (cf [7.3.24]).

**GRAPPE\_FLUIDE new key words:**

· Several key words allowing to locate the forces according to their type and their zone application were added (APPL\_FORC\_xxxx, DIRE\_FORC\_FPLAQ, UNITE\_IMPR\_xxxx) (cf [7.3.23]).

**HARLEQUIN modifications:**

· Amélioration of the method Harlequin (cf reference document) and addition of the key words COND\_LIM, JOINING, POIDS\_GROSSIER, POIDS\_FIN (cf [7.3.28]).

### **1.5.3 AFFE\_MATERIAU**

**New SECH\_REF:**

· Permet to inform the value of the drying of reference; with this concentration, withdrawal of desiccation is null. The user must think of informing K\_DESSIC if his field of drying is variable (cf [7.3.2]).

### **1.5.4 CALC\_FATIGUE**

**Removed MODEL:**

· The key word was not useful (cf [7.3.2]).

### **1.5.5 CALC\_FONCTION**

**METHOD new:**

· Amélioration of the calculation of the FFT by adding the method PROL\_ZERO in which one the signal with zeros supplements (cf [7.3.14]).

### **1.5.6 CALC\_G\_LOCAL\_T and CALC\_G\_THETA\_T**

### ***EXCIT replaces LOAD:***

· *The multiplicative coefficient of the loads was not taken into account. It is now the case, CHARGE, FONC\_MULT and TYPE\_CHARGE are added under EXCIT. Even modification in CALC\_G\_THETA\_T (cf [7.3.6]). By defect, it is not necessary besides to provide EXCIT, who is stored in the SD result (cf [§1.4.2]).*

### ***QUICKLY, new ACCE:***

· *Permettent to take into account the terms of inertia in the calculation of G (cf [7.3.4]).*

### ***1.5.7 CREA\_MAILLAGE***

#### ***New NOM\_CHAM:***

· *To burst elements (ECLA\_PG), it is necessary to know the family of points of Gauss used. For that, one must provide the name of the field (cf [7.3.19]).*

### ***1.5.8 CREA\_RESU***

#### ***MODEL, CHAM\_MATER, CARA\_ELEM new:***

· *Permettent to create a result of the elas\_mult type (MACRO\_ELAS\_MULT) (cf [7.3.7]).*

#### ***Instruction manual***

***U4.0- booklet: Use of the orders***

***HT-66/05/004/A***

***:***

***U4.01.03-A Page***

***: 5/22***

### ***1.5.9 BEGINNING***

#### ***FORMAT\_HDF=' OUI'/'NOT" replaces the key word factor HDF:***

· *The bases with format HDF (binary format portable enters of the machines of architectures*

*different) are now supported by askt, it is thus enough to specify if one wants to read one base with this format or not (cf [7.3.8]).*

**New VISU\_EFICAS:**

*· Permet to indicate (in the case-tests) if a command file is readable in Eficas or not (cf [7.3.5]).*

### **1.5.10 DEFI\_FICHER**

**FILE replaces NOM\_SYSTEME:**

*· In the idea of the simplification of the key words UNIT and FILE (cf [7.3.14]).*

**Turn over a free logical unit (primarily for the macros):**

*· In order not to cause conflict by choosing a logical unit already used, DEFI\_FICHER returns a free number of unit (cf [7.3.23]).*

### **1.5.11 DEFI\_MATERIAU**

**New LEMA\_SEUIL/\_FO:**

*· Introduction of a law of behavior derived from the law of Lemaître: in lower part of the threshold law is elastic, starting from the threshold, it behaves like a particular case of the law of Lemaître (cf [7.3.27]).*

**New GRANGER\_FP\_INDT:**

*· It acts of a law of Granger at a constant temperature (cf [7.3.24]).*

**New ENDO\_ORTH\_BETON:**

*· Orthotropic Loi of behavior of the concrete with taking into account of the damage (cf [7.3.23]).*

**New DRUCK\_PRAGER/\_FO (old DRUCKER\_PRAGER):**

*· Ajout of the possibility of calculating the sensitivity in 2D and 3D of the model of Drucker-Prager, the addition of the \_FO obliged has famous the model to avoid the conflicts of name (cf [7.3.21]).*

**VISC\_SINH replaces ROUSS\_VISC:**

*· With the addition of the laws of viscoplastic behavior VISC\_ISOT\_TRAC and VISC\_ISOT\_LINE, the viscous model being that already used by ROUSS\_VISC, the key word have famous summer to be more general (cf [7.3.19]).*

**New JOINT\_BA:**

*· Nouvelle law of behavior of steel-concrete connection in 2D (cf [7.3.8]).*

**BARCELONA - new ALPHAB:**

*· If it is not provided, the parameter is calculated by the code (cf [7.3.6]).*

**ECOU\_VISCi, ECOU\_ISOTi, ECOU\_PLASi, ECOU\_CINEi new:**

· Permettent to define the parameters of the single-crystal behaviors (cf [7.3.1]).

### **1.5.12 DEFI\_MODELE\_GENE**

**New OPTION=' REDUIT':**

· This option makes it possible to use the dynamic under-structuring by a method of modes of interface in order to reduce the size of the generalized modes, key words associated

:

**GROUP\_MA\_MAIT\_1/2, MAILLE\_MAIT\_1/2 (cf [7.3.18]).**

**Instruction manual**

**U4.0- booklet: Use of the orders**

**HT-66/05/004/A**

---

**Code\_Aster ®**

**Version**

**7.4**

**Date**

:

**25/01/05**

**Author (S):**

**Key COURTEOUS Mr.**

:

**U4.01.03-A Page**

**: 6/22**

### **1.5.13 TO DESTROY**

**ALARM new:**

· To be used only in the macros-orders, this key word makes it possible not to emit of alarm when one tries to remove a concept which does not exist (cf [7.3.27]).

**CLASS new:**

· Permet to remove an Aster object on the volatile basis (cf [7.3.8]).

### **1.5.14 DYNA\_NON\_LINE**

**New TETA\_METHODE:**

· Introduction of a formulation of speed for integration of the contact in dynamics. value of (parameter of the diagram of integration in time) can be selected between 0.5 and 1. ,

*this allows at the time of the resolution of a problem of contact with the method continues to make to vary dissipation during the phase of separation (cf [7.3.18], [7.3.22]).*

**New REAC\_ITER\_ELAS:**

· *Paramètre to control the frequency of reactualization of the secant matrix (cf [7.3.21]).*

### **1.5.15 DYNA\_TRAN\_EXPLI**

*It should be noted that this order will amalgamate with DYNA\_NON\_LINE in version 8.1.*

**New REAC\_ITER\_ELAS:**

· *Paramètre to control the frequency of reactualization of the secant matrix (cf [7.3.21]).*

### **1.5.16 END/CONTINUATION**

**FORMAT\_HDF=' OUI'/'NOT'** replaces the key word factor HDF:

· *The bases with format HDF (binary format portable enters of the machines of architectures different) are now supported by ask, it is thus enough to specify if one wants to or not see/write a base with this format (cf [7.3.8]).*

### **1.5.17 FORMULATE**

**NOM\_PARA, VALE new:**

· *The formulas are now unspecified Python expressions (it is enough that one can to evaluate all the same!). The names of parameters and the expression are defined under these two distinct key words (cf [7.3.21] and [U4.31.05]).*

### **1.5.18 IMPR\_FICO\_HOMA**

**UNITE\_CONF, UNITE\_DONN** replace **FICHER\_CONF, FICHER\_DONN:**

· *In the same spirit as in the paragraph [[§ 1.4.1](#)] (cf [7.3.23]).*

**MAJ\_CHAM** becomes a key word factor...

· *... to offer more flexibility in the choice of the fields to be updated at the time of one adaptation of grid (cf [7.3.20]).*

### **1.5.19 IMPR\_FONCTION**

*The order was completely rewritten (cf [7.3.13]).*

**Modified FORMAT:**

· *In a preoccupation with a homogenisation with the other orders, the format EXCEL becomes TABLE.*

· *Formats XMGRACE and AGRAF are dedicated to the tracers of the same name.*

· *The formats RESULT, ORDER and SEISM are removed.*

*Instruction manual*

*U4.0- booklet: Use of the orders*  
*HT-66/05/004/A*

---

**Code\_Aster** ®

Version

7.4

*Titrate:*

*Innovations and modifications of version 7*

*Date*

:

25/01/05

*Author (S):*

*Key COURTEOUS Mr.*

:

*U4.01.03-A Page*

: 7/22

***New PILOT (if FORMAT=' XMGRACE'):***

· *By defect, one produces a file ready to be to visualize in xmgrace. One also can to invite the various pilots available for xmgrace in order to produce a file ready to be introduced into a note of calculation like a file POSTSCRIPT, png or JPEG.*

***STYLE, COLOR, MARKER modified:***

· *These key words make it possible to define the style of each curve, they are now entirities that it is necessary to provide.*

***FREQ\_GRILLE\_X/Y replace GRILLE\_X/Y:***

· *Car agraf awaits a frequency of squaring and xmgrace a step of grid.*

***FREQ\_MARQUEUR is moved under the CURVED key word factor.***

***UNIT, UNITE\_DIGR modified:***

· *UNIT contains the logical number of unit of the file in which one produces the curve (file .dogr with format AGRAF). UNITE\_DIGR makes it possible to choose the logical unit associated with the file*

*.digr with format AGRAF.*

***TITLE replaces TITRE\_GRAPHIQUE, SOUS\_TITRE replaces COMMENT.***

***COUNT removed:***

· *It is the role of order IMPR\_TABLE.*

### **Removed RECU\_GENE:**

· *The order treats only the functions (or tablecloths). It is necessary to proceed in two times: to recover the values with RECU\_FONCTION, then impression itself with IMPR\_FONCTION.*

### **1.5.20 IMPR\_RESU**

#### **FILE, FORMAT moved:**

· *These key words are moved out of the key word factor RESU so that one cannot any more to use only one IMPR\_RESU to write in two different files (because the files were often incomplete) (cf [7.3.14]).*

### **1.5.21 IMPR\_TABLE**

*The order was completely rewritten (cf [7.3.27], [7.3.29]).*

#### **Modified FORMAT:**

- *In a preoccupation with a homogenisation with the other orders, the format EXCEL becomes TABLE, TABLE becomes TABLEAU\_CROISE (a parameter function of 2 others).*
- *One adds the format XMGRACE which produces a directly displayable file in xmgrace.*
- *Formats ASTER and AGRAF are unchanged (note: with format AGRAF, the file .digr is not created).*
- *Format MOT\_CLE is removed.*

#### **Removed TOUT\_PARA:**

· *It is enough to omit key word NOM\_PARA to select all the parameters of the table.*

#### **Modified SORTING:**

- *One can sort according to NR parameters, in the event of equality on a parameter, one passes to the following;  
ORDER is worth GROWING or DECREASING.*
- *CRITERION and PRECISION are removed.*

#### **Instruction manual**

**U4.0- booklet: Use of the orders**

**HT-66/05/004/A**

**Date**

**:**

**25/01/05**

**Author (S):**

**Key COURTEOUS Mr.**

:

**U4.01.03-A Page**

**: 8/22**

**PAGINATION modified:**

· *The number of parameter is unlimited.*

**TITLE replaces TITRE\_TABLE.**

**1.5.22 INFO\_EXEC\_ASTER**

**LISTE\_INFO new possibility: ETAT\_UNITE**

· *One can know if a file attached to a logical unit currently is opened or closed (cf [7.3.20]).*

**1.5.23 LIRE\_FONCTION**

*The order was completely rewritten (cf [7.3.10], [7.3.21], [U4.32.02]).*

**New INDIC\_xxxx, FORMAT, TYPE, SEPAR:**

· *Permettent to build a real, complex function or a tablecloth starting from files of which the format can slightly vary.*

**1.5.24 LIRE\_RESU**

**Removed NOM\_CHAM:**

· *This key word is useless out of the specific blocks to each format (cf [7.3.28]).*

**1.5.25 MACR\_ADAP\_MAIL/MACR\_INFO\_MAIL**

**Modified NON\_SIMPLEXE:**

· *Traitement of the quadrangular elements (cf [7.3.20]).*

**1.5.26 MACR\_FIAB\_IMPR**

**New PARA\_SENSI:**

· *Nécessaire to treat the case of the sensitivity (cf [7.3.24]).*

**1.5.27 MACRO\_MISS\_3D**

**VERSION new:**

· *Permet to specify the version of the Miss3D software used (cf [7.3.27]).*

**1.5.28 MECA\_STATIQUE**

***New METHODE=' FETI':***

***· Introduction of a method of resolution by decomposition of fields of the Feti type.  
New key words simple associates: PARTITION, RENUM, RESI\_RELA, NMAX\_ITER,  
TYPE\_REORTHO\_DD, NB\_REORTHO\_DD, PRE\_COND, SCALING, VERIF\_SDFETI,  
TEST\_CONTINU (cf [7.3.3]).***

***New INFO\_FETI:***

***· To modulate the quantity information to print at the time of a resolution by the Feti method  
(cf [7.3.27]).***

***1.5.29 MODE\_ITER\_INV/MODE\_ITER\_SIMULT/NORM\_MODE***

***SENSITIVITY new:***

***· Possibilité of making calculations of sensitivities for the generalized and quadratic problems  
(cf [7.3.15]).***

***Instruction manual***

***U4.0- booklet: Use of the orders***

***HT-66/05/004/A***

### **1.5.30 MODI\_MAILLAGE**

**ORIE\_FISSURE** replaces **ORIE\_CONTACT**:

· *This functionality is used for the joined elements (cf [7.3.20]).*

### **1.5.31 POST\_RCCM**

New **TABL\_SIGM\_THER**:

· *Permet to calculate \**

*S starting from the statement of the constraints under thermal loading only*

*N*

*(cf [7.3.6]).*

### **1.5.32 STAT\_NON\_LINE**

New **REAC\_ITER\_ELAS**:

· *Paramètre to control the frequency of reactualization of the secant matrix (cf [7.3.21]).*

### **1.5.33 TEST\_FICHER**

New **EXPR\_IGNORE**:

· *Permet not to preserve certain lines of the file tested by using expressions regular (cf [7.3.22]).*

**2**

***Innovations between 7.2 and 7.3***

**2.1 News**

**orders**

**2.1.1 MACR\_FIABILITE**

***This macro-order calculates the probability that a physical variable (displacement, forced,...) exceed a threshold defined by the user according to a certain number of parameters which will have been***

***defined as sensitive by the user. These significant parameters can be the Young modulus, Poisson's ratio, a pressure, etc***

***The macro-order calls upon the software MEFISTO which is external in Code\_Aster, and which puts in***

***work method FORM. (cf [7.2.11]).***

**2.1.2 STANLEY**

***Stanley, tool for interactive postprocessing, was already present in version 7; this macro-order simplify its call since one now launches it like an ordinary order. (cf [7.2.25]).***

**2.1.3 TEST\_FICHER**

***This macro-order makes it possible to test nonthe regression of the orders which produce files, to the attention of the developers (cf [7.2.25]).***

## **2.2 Orders reabsorbed**

### **2.2.1 FACT\_INTE\_SPEC**

*This order was amalgamated with GENE\_FONC\_ALEA (cf [7.2.3]).*

### **2.2.2 MACR\_GOUJ2E\_MAIL and MACR\_GOUJ2E\_CALC**

*These two macro-orders are reabsorbed. The method for calculation is preserved in command files zzzz120a and zzzz120b which validated these functionalities. (cf [7.2.14]).*

## **2.3 Orders modified**

### **2.3.1 AFFE\_CARA\_ELEM**

*New RIGI\_MISS\_3D:*

*· Permet to affect the terms of a matrix of impedance of ground calculated by MISS3D for one frequency of extraction given (cf [7.2.2]).*

### **2.3.2 AFFE\_MODELE**

*\*\_HH2D new modelings:*

*· These modelings make it possible to take into account two phases in both components; the pressure of dissolved air is connected to the pressure of dry air by the law of Henry (cf [7.2.7]).*

*GRILLE\_MEMBRANE new modeling:*

*· It acts of a new element of tablecloths of reinforcement which works only out of membrane, not of ddl of rotation (cf [7.2.21]).*

*Instruction manual*

*U4.0- booklet: Use of the orders*

*HT-66/05/004/A*

---

*Date*

*:*

**25/01/05**

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U4.01.03-A Page**

**: 11/22**

### **2.3.3 AFFE\_CHAR\_MECA/AFFE\_CHAR\_MECA\_F**

**New GRAPPE\_FLUIDE:**

*· Permet to take into account the fluid forces due to the displacement of the bunch in fluid which bathes the internal elements of the heart. (cf [7.2.2]).*

**New TOLE\_PROJ:**

*· Permet to adjust the projection of the nodes slaves towards the meshes Masters (cf [7.2.1]).*

**CONTACT famous key words:**

*· GROUP\_MA\_MAIT,*

*MAILLE\_MAIT,*

*GROUP\_MA\_ESCL,*

*MAILLE\_ESCL replace*

*respectively GROUP\_MA\_1, MAILLE\_1, GROUP\_MA\_2, MAILLE\_2 (cf [7.2.4]).*

### **2.3.4 ASSE\_MAILLAGE**

**OPERATION, MAILLAGE\_1, GRID new:**

*· Three types of operation are now available SOUS\_STR, SUPERIMPOSES, JOINING (cf [7.2.4]).*

### **2.3.5 CALC\_CHAM\_ELEM/CALC\_ELEM**

**Doubled bloom:**

*· These two orders made doubled bloom on the majority of the calculated options, only some options persist in CALC\_CHAM\_ELEM (cf [7.2.17]).*

### **2.3.6 CALC\_FATIGUE**

**New TYPE\_CHARGE:**

*· Définit the type of loading (periodic or not), under the key word CRITERION, the choice is thus restricted according to the type of loading (cf [7.2.5]).*

**CRITERE=' DOMM\_MAXI', PROJECTION, DELTA\_OSCI new:**

*· These key words are associated the new criterion adapted to the nonperiodic loadings; it acts of a criterion with variable amplitude based on a critical level selected according to*

*induced maximum damage (cf [7.2.5]).*

**CRITERE=' DANG\_VAN\_\_MODI\_AC'/new "DANG\_VAN\_MODI\_AV":**

*· It acts of a criterion with variable amplitude based on a critical level selected from maximum damage. This criterion which is adapted if the loading is not periodical is an evolution of the criterion of original DANG VAN. "AC" for constant amplitude, "AV" for variable amplitude (cf [7.2.11]).*

### **2.3.7 CALC\_G\_THETA\_T**

*New type for the field:*

*· One can now provide a field of the cham\_no\_depl\_r type (and to build it made-to-order!) in the place of that provided by CALC\_THETA (cf [7.2.8]).*

### **2.3.8 CALC\_NO**

**GROUP\_MA\_RESU, GROUP\_NO\_RESU, MAILLE\_RESU, NOEU\_RESU new:**

*· Permettent to specify the zone on which the field by element will be tiny room before calculating the values with the nodes because one could obtain incorrect results when a node is with border of two modelings (cf [7.2.7]).*

*Instruction manual*

*U4.0- booklet: Use of the orders*

*HT-66/05/004/A*

---

**Date**

**:**

**25/01/05**

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U4.01.03-A Page**

**: 12/22**

### **2.3.9 CREA\_MAILLAGE /CREA\_RESU**

**ECLA\_PG new possibilities:**

*· One can now burst a grid (by creating an element by point of Gauss) on one*

*part only of one grid; and in 2D, to give a fictitious thickness to flattened elements.*

**Caution:**

*The parameters provided to CREA\_MAILLAGE and CREA\_RESU must be coherent: same groups of meshes given in the same order (cf [7.2.25]).*

**2.3.10 DEFI\_FONCTION**

**NOM\_PARA new values:**

- *Added Noms of parameter: NORM and DSP (cf [7.2.4]).*

**2.3.11 DEFI\_GROUP**

**CREA\_GROUP\_NO/TOUT=' OUI' limited to the option TUNNEL:**

- *The use of TOUT=' OUI' is not available for all the options, only for the option TUNNEL (cf [7.2.8]).*

**2.3.12 DEFI\_MATERIAU**

**BARCELONA new behavior for KIT\_HHM and KIT\_THHM:**

- *Loi of mechanical and hydrous behavior of the unsaturated grounds. This model utilizes two criteria, a mechanical criterion of plasticity which is that of CAM\_CLAY and another criterion hydrous controlled by suction (cf [7.2.21]).*

**GLRC/GLRC\_FO new behavior:**

- *Loi of behavior of the concrete plates arms written in generalized efforts; finite element associated DKTG (on meshes TRIA3 and QUAD4) (cf [7.2.4]).*

**New CORR\_ACIER:**

- *Elastoplastic Modèle endommageable of a steel in which plastic deformation with rupture depends on the rate of corrosion (cf [7.2.23]).*

**VISC\_IRRA\_LOG new behavior:**

- *Viscoelastic Loi of behaviour for the axial creep of the tubes guides under irradiation (cf [7.2.1]).*

**DRUCKER\_PRAGER new behavior:**

- *Loi of behavior for the soil mechanics (cf [7.2.7]).*

**New LIQU\_AD\_GAZ\_VAPE:**

- *Rate mixing of the air dissolved for the THM (law of Henry) which connects the pressure of air dissolved to pressure of dry air (cf [7.2.7]).*

### **DOMM\_A, DOMM\_B, COEF\_CISA\_TRAC new:**

· *Associés the criterion of tiredness DOMM\_MAXI of CALC\_FATIGUE (cf [7.2.5]).*

### **EPSP\_SEUIL, EXP\_S new:**

· *Associés the criterion of tiredness DOMMA\_LEMAITRE of CALC\_FATIGUE (cf [7.2.19]).*

### **LAMBDA and D\_LAMBDA\_TEMP removed under THM\_\*:**

· *Thermal conductivity is now defined like the product of three functions of temperature (LAMB\_T), of saturation (LAMB\_S) and porosity (LAMB\_PHI) more one constant (LAMB\_CT), as well as the three derived from functions (D\_LB\_T, D\_LB\_S, D\_LB\_PHI) (cf [7.2.10]).*

*In the thermal case, only LAMB\_T is obligatory, the other functions being then taken equal to one and their derivative null.*

*Instruction manual*

*U4.0- booklet: Use of the orders*

*HT-66/05/004/A*

*: 13/22*

### **2.3.13 GENE\_FONC\_ALEA/GENE\_MATR\_ALEA/GENE\_VARI\_ALEA**

· *These orders were completely altered; FACT\_GENE\_ALEA was reabsorbed with profit of GENE\_FONC\_ALEA. One will refer to documentations of the orders for new syntax of use (cf [7.2.3]).*

### **2.3.14 IMPR\_RESU**

**FORMAT=' GMSH'/VERSION new defect:**

· *The version of file GMSH by defect is now 1.2 (in which GMSH knows post-to treat the quadrangles): the quadrangles are not cut out in triangles (cf [7.2.9]).*

### ***2.3.15 INCLUDE\_MATERIAU***

***New materials available in the catalogue material:***

- ***Z3CN20-09M, Z6NCTDV25-15 (cf [7.2.10], to see on the Intranet Code\_Aster under Use/Materials).***

### ***2.3.16 MACR\_RECAL***

***New WEIGHT:***

- ***One can balance the various curves on which retiming (cf [7.2.4] is made).***

### ***2.3.17 MODI\_MAILLAGE***

***SYMMETRY new:***

- ***Permet to take the symmetrical one of a grid compared to a line or a plan according to dimension (cf [7.2.16]).***

### ***2.3.18 POST\_ELEM***

***New:***

- ***One can now use POST\_ELEM after a multiple resolution with MACRO\_ELAS\_MULT (cf [7.2.22]).***

### ***2.3.19 POST\_K1\_K2\_K3***

***VERY new:***

- ***Permet to calculate the stress intensity factors on all the nodes of the meshes composing the bottom of crack (cf [7.2.4]).***

### ***2.3.20 PROJ\_CHAMP***

***New DISTANCE\_MAX:***

- ***Permet to astutely project fields of a model A towards a model B. When nodes of the grid B are not in an element of the grid A and which they are beyond one certain distance, the field is not projected (cf [7.2.16]).***

***NUAG\_DEG\_\* removed methods:***

- ***These methods of projection of fields were removed, results vague (cf [7.2.22]).***

### ***2.3.21 POST\_RCCM***

***New TYPE\_RESU\_MECA, modification of the options:***

- ***This key word can take the values "UNIT" or "PIPING", OPTION=' FATIGUE' replace B3200 and B3600... (cf [7.2.17]).***

***Instruction manual***

### **2.3.22 MACRO\_CARA\_POUTRE**

**RT new result:**

· *One can obtain under this key word of ray of torsion of the section of a beam (cf [7.2.2]).*

### **2.3.23 STAT\_NON\_LINE/DYNA\_NON\_LINE**

**New ALGO\_ID:**

· *One can thus use all the behaviors (small deformations) 3D in the elements of bar, grids, multifibre beams, one extended the method suggested by R. De Borst for plane constraints with the behaviors 1D. That is translated, as for the constraints plane, by 4 internal variables (cf [7.2.18]).*

**Obligatory ETAT\_INIT in mode réentrant (when the result is enriched) (cf [7.2.1]).**

**BARCELONA new:**

· *Comportement of the grounds in medium unsaturated (cf [7.2.21]).*

**New GLRC:**

· *Comportement of the concrete plates arms written in generalized efforts (cf [7.2.4]).*

**CORR\_ACIER, CORROSION new:**

· *Permettent to provide the parameters necessary to the elastoplastic model endommageable of a steel in which the plastic deformation with rupture depends on the rate of corrosion (cf [7.2.23]).*

### ***New SOUS\_STRUC:***

· *Intégration of the static macronutrients. The application concerned is to optimize the resolution of problems of important size in which only a restricted part with a behavior nonlinear (cf [7.2.23]).*

### ***THER\_HOMO, THER\_POLY removed:***

· *Suppression of the thermal law of behavior under RELATION\_KIT in THM (cf [7.2.16]).*

### ***2.3.24 THER\_NON\_LINE\_MO***

*The order is not any more réentrante because only one moment is calculated (stationary calculation in reference mark mobile).*

***3.1 News***

## **orders**

### **3.1.1 CALC\_PRECONT**

*This order makes it possible to define and apply the prestressing of the cables of a concrete structure armed by taking into account various types of anchoring, and while allowing to tend individually each cable while respecting the standards of the BPEL (cf [7.0.14]).*

### **3.1.2 CREA\_TABLE**

*This order makes it possible to create a table starting from a function or of two lists (cf [7.1.17]).*

### **3.1.3 DYNA\_TRAN\_EXPLI**

*It is about the first grinding of the operator of dynamics clarifies in which all them possibilities were not introduced yet (master-slave contact for example) (cf [7.1.16]).*

### **3.1.4 EXTR\_TABLE**

*This order makes it possible to recover the contents of a cell of a table; only the type MATR\_ASSE\_GENE\_R is treated for the moment (cf [7.1.17]).*

### **3.1.5 MACR\_CABRI\_MAIL MACR\_CABRI\_CALC**

*These orders make it possible to net supports automatically, and of launching calculations on these grids (cf [7.1.5]).*

## **3.2 Orders reabsorbed**

*Orders MACRO\_CHAR\_F\_U and MACRO\_MADMACS were removed in version 7.1.*

## **3.3 Orders re-elected**

- *MACR\_CARA\_POUTRE replaces MACRO\_CARA\_POUTRE.*
- *DEFI\_FICHER replaces DEFUFI and TO CLOSE (these last will be reabsorbed in version 7.3). Moreover, DEFI\_FICHER gives access a file by indicating its name system (and not only with its number of logical unit FORTRAN) (cf [7.1.16]).*

## **3.4 Modifications common to several orders**

### **3.4.1 FOND\_FISS replaces FUND, FOND\_3D**

*In orders CALC\_G\_LOCAL\_T, CALC\_G\_THETA\_T, CALC\_THETA, POST\_K1\_K2\_K3  
· Homogénéisation of the vocabulary in breaking process (cf [7.0.9]).*

*: 16/22*

### **3.4.2 Options of prepacking of the solver key word PRE\_COND**

*In orders CALC\_FORC\_AJOU,*

*CALC\_MATR\_AJOU,*

*DYNA\_NON\_LINE,*

*MACR\_ASCOUF\_CALC, MACR\_ASPIC\_CALC, MACRO\_MATR\_AJOU, MECA\_STATIQUE,*

*STAT\_NON\_LINE, THER\_LINEAIRE, THER\_NON\_LINE, THER\_NON\_LINE\_MO*

*· Option PRE\_COND='DIAG' is removed, only remains option LDLT\_INC (incomplete)  
(cf [7.0.14]).*

## **3.5 Orders**

*modified*

### **3.5.1 AFFE\_CARA\_ELEM**

**New GROUP\_MA\_POII:**

*· Mot-clé introduced to affect characteristics of RIGI\_PARASOL on elements of  
type POII (cf [7.0.14]).*

### 3.5.2 AFFE\_CHAR\_MECA

#### *New DDL\_POUTRE:*

- *Permet to impose boundary conditions in the local reference mark of a beam (cf [7.0.10]).*

#### *CONNECTION new:*

- *Under DDL\_IMPO, to block all displacements of a blow (cf [7.1.5]).*

#### *SIGM\_BPEL default value:*

- *The default value is now “NOT”, the value “YES” is usually used only for the setting in prestressed cables (cf [7.0.13]).*

### 3.5.3 AFFE\_CHAR\_MECA\_C

#### *CONNECTION new:*

- *Under DDL\_IMPO, to block all displacements of a blow (cf [7.1.5]).*

### 3.5.4 AFFE\_CHAR\_MECA\_F

#### *CONNECTION new:*

- *Under DDL\_IMPO, to block all displacements of a blow (cf [7.1.5]).*

#### *New EFFET\_FOND:*

- *Permet the taking into account of the basic effect according to time (cf [7.0.1]).*

### 3.5.5 AFFE\_MATERIAU

#### *GROUP\_NO, NODE removed:*

- *The assignment is not possible that on meshes (cf [7.1.8]).*

### 3.5.6 AFFE\_MODELE

#### *SHB8 new modeling:*

- *Nouvel element of hull under-integrated without mode of blocking (cf [7.1.18]).*

#### *AFFE modification:*

- *possibility of providing a list under AFFE, with rule of overload (cf [7.1.18]).*

#### *Instruction manual*

### ***3.5.7 CALC\_ELEM***

***EQUI\_ELNO\_SIGM different method of calculation:***

***Equivalent constraints (Von Mises, Tresca,...) were calculated starting from the constraints extrapolated with the nodes. One calculates from now on the equivalent constraints by extrapolation of***

***constraints equivalent calculated to the points of Gauss (as for the internal variables). only stress fields provided are thus SIEF\_ELGA\_DEPL into linear and SIEF\_ELGA in nonlinear.***

***On the other hand for the elements of hulls, the mode of calculation of the equivalent constraints does not have***

***changed: the user must calculate the stress field in a point thickness***

***(SIGM\_ELNO\_DEPL into linear and SIGM\_ELNO\_COQU into nonlinear), and the option EQUI\_ELNO\_SIGM calculate the invariant of this field to the nodes.***

### ***3.5.8 CALC\_FATIGUE***

***CRITERION news possibility:***

***· Ajout of the criterion of DANG\_VAN (cf [7.0.7]).***

***MODEL, GRID, GROUP\_MA, MESH, GROUP\_NO, NODE new:***

***· Permettent post-to treat with the nodes on part of the grid by using the method of critical plan (cf [7.1.7]).***

### ***3.5.9 CALC\_FONC\_INTERP***

***VALE\_PARA replaces VALE\_R;***

***NOM\_PARA,***

***NOM\_PARA\_FONC,***

***VALE\_PARA\_FONC,***

**LIST\_PARA\_FONC,**  
**INTERPOL\_FONC,**  
**PROL\_GAUCHE\_FONC, PROL\_DROITE\_FONC new:**

- *Possibilité of creating a tablecloth starting from a formula with two parameters (cf [7.0.14]).*
- *The order is not any more réentrante: it treats a function and produces a function or one tablecloth.*

### **3.5.10 CALC\_FONCTION**

**New ABS:**

- *Calcul the absolute value of a function (cf [7.0.14]).*

**OPPOSITE new:**

- *Calcul the reverse of a function (cf [7.0.14]).*

**New ECART\_TYPE:**

- *Calcul of the standard deviation of a function (cf [7.0.15]).*

### **3.5.11 CALC\_G\_THETA\_T**

**CALC\_DG removed option:**

- *The calculation of derived from G follows the standard formalism now (key word SENSITIVITY) (cf [7.1.12]).*

### **3.5.12 COMB\_SISM\_MODAL**

**TYPE\_COMBI replaces STANDARD:**

- *Under the key words factors COMB\_MULT\_APPUI and COMB\_DEPL\_APPUI. Possible choices are “QUAD” and “LINE”, “ABS” was removed (cf [7.0.14]).*

### **3.5.13 CREA\_CHAMP**

**OPTION new:**

- *Permet to initialize a field as if it had been created by such option (cf [7.0.15]).*

### **3.5.14 CREA\_MAILLAGE**

**New COQU\_VOLU:**

- *Crée a voluminal grid starting from a surface grid and a thickness (cf [7.1.11]).*

**New LINE\_QUAD:**

- *Crée a quadratic grid starting from a grid made up of linear elements (cf [7.0.5]).*

**New QUAD\_TRIA3:**

- *Crée triangular meshes with three nodes starting from quadrangles (cf [7.1.9]).*

### **3.5.15 BEGINNING/CONTINUATION**

**New HDF:**

- *Définir parameters for the reading of a base in format HDF (portable between machines) (cf [7.1.16]).*

### **3.5.16 DEFI\_CABL\_BP**

**New CONE:**

- *Permet to define a cone which will support the tension loads of the cable (cf [7.0.16]).*

**Note:**

*It is now about an macro-order.*

### **3.5.17 DEFI\_GROUP**

**New APPUI\_LACHE:**

- *Définit the group of the meshes being based on a node or a group of nodes (releases: “containing at least a node of the group”) (cf [7.1.10]).*

**New TUNNEL:**

- *Définit the group of the nodes contained in a tunnel describes by its axis and its ray (cf [7.0.16]).*

**ALARM new:**

- *Permet to decontaminate the release of the alarms emitted normally by the order.*

**Caution:**

*Must be used only by macro-orders which are ensured in addition of the validity groups obtained.*

**3.5.18 DEFI\_MATERIAU**

**New BETON\_ECRO\_LINE:**

- *Prise in account of containment for model ENDO\_ISOT\_BETON, one adds like parameter maximum material SYC forced in simple compression (cf [7.0.17]).*

**New BETON\_UMLV\_FP:**

- *Ajout of a relation of behavior for the taking into account of the clean creep of the concrete (cf [7.0.4]).*

**BPEL\_ACIER/SY becomes F\_PRG:**

- *F\_PRG is the guaranteed constraint of the maximum loading with rupture (cf [7.1.17]).*

Version

7.4

**Titrate:**

*Innovations and modifications of version 7*

Date

:

25/01/05

Author (S):

Key **COURTEOUS Mr.**

:

U4.01.03-A Page

: 19/22

**New COMP\_THM:**

· Regroupement of the parameters required for a calculation THM according to the mixing rate used (cf [7.1.18]).

**DIS\_CONTACT/ANGLE\_i and MOMENT\_i:**

· For the connection grid-pencil, one introduces the angles and moments function of the temperature and fluence (cf [7.1.7]).

**In fatigue:**

· Ajout of the CRITERION of DANG\_VAN (cf [7.0.7]).  
· For criterion MATAKE, ENDU\_FT is replaced by COEF\_FLEX\_TORS.

### **3.5.19 TO DESTROY**

**New OBJECT:**

· Possibilité of destroying objects associated with concepts inaccessible to the user (cf [7.1.9]).

### **3.5.20 DYNA\_LINE\_TRAN and DYNA\_NON\_LINE**

**SENSITIVITY new:**

· Ajout of the calculation of derived from the fields results compared to the data material or boundary conditions (cf [7.1.5] for DYNA\_LINE\_TRAN, [7.1.3] DYNA\_NON\_LINE).

### **3.5.21 END**

**New HDF:**

· Définir parameters for the writing of a base in format HDF (portable between machines)

(cf [7.1.16]).

### **3.5.22 FORMULATE**

**Removed ENTIRETY:**

· *The whole formulas are henceforth prohibited (cf [7.0.17]).*

### **3.5.23 IMPR\_FICO\_HOMA**

*There are changes of syntax in this procedure, called by MACR\_ADAP\_MAIL, which are not thus not described here.*

### **3.5.24 IMPR\_RESU**

**VERSION new:**

· *Permet to specify the level of version of the files to format GMSH. With version 1.2 (available in the recent versions of GMSH), the quadrangles are not cut out any more in triangle, GMSH knowing to treat all the linear elements (cf [7.0.3]).*

### **3.5.25 IMPR\_TABLE**

**New TITRE\_TABLE:**

· *Possibilité of defining a title during the impression of a table (cf [7.0.16]).*

### **3.5.26 INCLUDE\_MATERIAU**

**New UNITE\_LONGUEUR:**

· *Permet to use the data of the catalogue material with the millimetre like unit of length (cf [7.0.14]).*

*Instruction manual*

*U4.0- booklet: Use of the orders*

*HT-66/05/004/A*

### **3.5.27 LIRE\_CHAMP**

**New INST:**

· **One can now locate it (S) field (S) with reading with the moment in a file with format MED (cf [7.1.10]).**

### **3.5.28 LIRE\_RESU**

**FORMAT replaces FORMAT\_IDEAS:**

· **One specifies behind this key word the format of reading: IDEAS or IDEAS\_DS58 (cf [7.0.13]).**

### **3.5.29 MACR\_ADAP\_MAIL**

**New NON\_SIMPLEXE:**

· **Permet acceptance of the quadrangular, hexahedral, pentaedric elements (which are not refined) in a grid subjected to Homard (cf [7.1.10]).**

**New MAILLAGE\_FRONTIERE:**

· **Possibilité of providing a grid for the follow-up of border (cf [7.1.10]).**

**TYPE\_CHAM modification:**

· **One now awaits the same thing as in order CREA\_CHAMP (cf [7.0.12]).**

### **3.5.30 MACR\_INFO\_MAIL**

**New NON\_SIMPLEXE and MAILLAGE\_FRONTIERE:**

· **Voir MACR\_ADAP\_MAIL.**

### **3.5.31 MECA\_STATIQUE**

**New INST\_FIN:**

· **The operator is now réentrant to be able to treat long transients (cf [7.1.8]).**

### **3.5.32 MODE\_ITER\_SIMULT**

**APPROACH new possibility:**

· **Ajout of the approach "COMPLEXES" to deal with the quadratic problem with the eigenvalues, for the strongly deadened cases for example (cf [7.0.12]).**

### **3.5.33 MODI\_MAILLAGE**

### ***New ORIE\_SHB8:***

- *Permet to direct the elements of hull SHB8 (cf [7.1.18]).*

### ***3.5.34 MODI\_OBSTACLE***

#### ***Removed TUBE\_NEUF:***

- *The key word was moved in order POST\_USURE (cf [7.0.2]).*

### ***3.5.35 MODI\_REPERE***

#### ***GROUP\_MA, MESH, GROUP\_NO, NODE new:***

- *Permet to restrict the change of reference mark to part of the grid (cf [7.0.9]).*

### ***3.5.36 PROJ\_CHAMP***

#### ***SENSITIVITY new:***

- *Permet to project fields derived from a grid on another (cf [7.1.10]).*

### ***3.5.37 POST\_USURE***

#### ***New TUBE\_NEUF:***

- *Permet to provide new values of wear (cf [7.0.2]).*

### ***3.5.38 POST\_RCCM***

### ***New TYPE\_KE***

- *Offre two methods of calculation of Ke.*

### ***3.5.39 PRE\_GMSH***

#### ***Removed MODI\_QUAD:***

- *This functionality is included in CREA\_MAILLAGE and applies to an Aster grid some is its origin (cf [7.0.6]).*

#### ***Note:***

*PRE\_GMSH is again a procedure.*

### ***3.5.40 PRE\_IDEAS***

#### ***New CREA\_GROUP\_COUL:***

- *Permet to create or not the groups associated with the colors with IDEAS (cf [7.0.2]).*

### ***3.5.41 STAT\_NON\_LINE***

***RESI\_REFE\_RELA, SIGM\_REFE, EPSI\_REFE, FLUX\_THER\_REFE, FLUX\_HYD1\_REFE,  
New FLUX\_HYD2\_REFE:***

- *Nouvelle method for the test of convergence compared to a definite value of reference for each size (cf [7.0.16]).*

#### ***SELECTION new:***

- *Choix of parameter of piloting: NORM\_INCR\_DEPL, ANGL\_INCR\_DEPL, RESIDUE: one respectively minimize the increment of displacement (defect), the angle between  $u_+$  and  $U$ , the residue (cf [7.0.9]).*

#### ***ETA\_PILO\_R\_MAX, ETA\_PILO\_R\_MIN, PROJ\_BORNES new:***

- *Permettent to define the terminals of the interval of research (cf [7.0.9]).*

#### ***PAS\_MIN\_CRIT, ITER\_LINE\_CRIT, RHO\_MAX, RHO\_MIN, RHO\_EXCL new:***

- *Bornes of linear research in the event of piloting (cf [7.0.9]).*

#### ***New CRIT\_FLAMB:***

- *Recherche of the modes of buckling of a structure (cf [7.1.17]).*

#### ***SENSITIVITY new:***

- *Introduction of calculations of sensitivity into nonlinear (cf [7.1.3]).*

### ***3.5.42 TEST\_TABLE***

#### ***SENSITIVITY new:***

- *Permet the test of the derived tables (cf [7.1.12]).*

***Innovations and modifications of version 8***

## **Summary:**

*The object of this document is to offer a global vision of the modifications of syntax and new possibilities*

*orders of Code\_Aster occurred between each version since version 8.0.*

*Index A of this document thus gives a report on the changes introduced since version 8.0 of December 2004*

*(identical to version 7.4) and valid for version 8.2 of December 2005.*

*For more precise details, one will consult the documentation of the orders and the file histor of corresponding under-version (e.g.: [8.0.7], section Development of the [www.code-aster.org](http://www.code-aster.org) site). The impacted orders are listed alphabetically.*

**Code\_Aster** ®

Version

8.2

Titrate:

*Innovations and modifications of version 8*

Date

:

30/01/06

Author (S):

Key **COURTEOUS Mr.**

:

U4.01.04-A Page

: 2/8

**1**

**Innovations between 7.4/8.0 and 8.2**

**1.1 Modifications**

**general**

**1.1.1 Local criteria of convergence**

*The local criteria of convergence are by nature relevant only for a given behavior; the accepted residue, the diagram of integration or the iteration count can now be defined of manner different for each behavior from the model.*

*In the field of syntax, key words RESI\_INTE\_RELA, INTER\_INTE\_REAL, INTER\_INTE\_MAXI, RESO\_INTE are moved of CONVERGENCE towards COMP\_INCR/COMP\_ELAS (of which an occurrence each behavior defines).*

*The orders concerned are DYNA\_NON\_LINE, DYNA\_TRAN\_EXPLI, STAT\_NON\_LINE and in cascade macro-orders CALC\_PRECONT, MACR\_ASCOUF\_CALC, MACR\_ASPIC\_CALC, MACR\_CABRI\_CALC.*

### **1.1.2 Solvor MUMPS**

*A new direct solvor is available in Code\_Aster: MUMPS.*

*It makes it possible to solve problems known with the traditional solveurs when the matrix is not positive (case XFEM, incompressible elements,...).*

*It is usable by orders DYNA\_NON\_LINE, MECA\_STATIQUE, RESO\_LDLT, STAT\_NON\_LINE, THER\_LINEAIRE and THER\_NON\_LINE (cf [8.0.14]).*

*Notice for the version local*

*This solvor does not form part of the sources of Code\_Aster, it acts of an external package.*

### **1.1.3 Solvor FETI**

*Solvor FETI is a parallel solvor by decomposition of fields.*

*He is under development; its field of application is thus limited in version 8.2.*

## **1.2 News orders**

### **1.2.1 CALC\_TABLE**

*This order makes it possible to handle the data of the tables to the manner of a spreadsheet. The order makes it possible to carry out operations on the data of the tables. Operations currently available are:*

*.  
concaténer/to combine two tables having common parameters,  
.  
to apply a formula,  
.*

*to re-elect parameters,*

.

*to filter the lines according to certain criteria,*

.

*to extract from the columns of a table,*

.

*to order the lines.*

### **1.2.2 INFO\_FONCTION/CALC\_FONCTION**

*Order CALC\_FONCTION was deeply rewritten so that it is simple and fast of y  
to introduce new generic treatments at the request of the users.*

*Thus, only the operations which calculate a function (or a tablecloth) starting from other functions  
were*

*preserved in CALC\_FONCTION.*

*It should be noted that the operation of smoothing wraps spectra of floor (SRO), LISS\_ENVELOP,  
was*

*review according to regulations' of EDF Septen.*

*Instruction manual*

*U4.0- booklet: Use of the orders*

*HT-62/06/004/A*

---

*Code\_Aster ®*

*Version*

*8.2*

*Titrate:*

*Date*

:

*30/01/06*

*Author (S):*

*Key COURTEOUS Mr.*

:

*U4.01.04-A Page*

*: 3/8*

*All the operations on the functions which produce another thing today (it acts only of  
count) are now available in order INFO\_FONCTION:*

*· MAX, RMS, NOCI\_SEISME, STANDARD and ECART\_TYPE.*

### **1.2.3 LIRE\_FORC\_MISS/LIRE\_IMPE\_MISS**

***LIRE\_IMPE\_MISS and LIRE\_FORC\_MISS make it possible respectively to create a generalized matrix and a generalized vector of seismic force starting from the matrix of impedance of ground or the forces seismic of ground created by MISS3D for a frequency of extraction given.***

#### ***1.2.4 POST\_MAIL\_XFEM/POST\_CHAM\_XFEM***

#### ***1.2.5 MAC\_MODES***

*This order makes it possible to calculate a criterion of orthogonality, the Modal Criterion Insurance, enters two modal bases (in general, experimental and a one calculated) (cf [8.1.14]).*

### ***1.3 Orders modified***

#### ***1.3.1 AFFE\_CARA\_ELEM***

***Removed CARA\_SECT:***

*· Mot-clé not used (cf [8.0.6]).*

***New RIGI\_PARASOL/GROUP\_MA\_POI1 and GROUP\_MA\_SEG2:***

*· Permettent to define a carpet of springs to model a displacement of foundation, one landslide and to apply boundary conditions in efforts (cf [8.0.17]).*

#### ***1.3.2 AFFE\_CHAR\_CINE and AFFE\_CHAR\_CINE\_F***

***AFFE\_CHAR\_CINE and AFFE\_CHAR\_CINE\_F are usable with STAT\_NON\_LINE and DYNA\_NON\_LINE.***

***GROUP\_MA, MESH new:***

*· Définition of the zones to be forced (cf [8.0.6]).*

#### ***1.3.3 AFFE\_CHAR\_MECA***

***CONTACT/new METHODE=' VERIF':***

*· Permet to check if there is or not matter interpenetration a posteriori without paying the overcost resolution with contact (cf [8.0.7]).*

***New CONTACT/SLIDE, ALARME\_JEU:***

*· Permet to carry out with the method of the active constraints the “sticking” contact, surfaces in opposite cannot fall apart, by emitting an alarm if the play becomes excessive (value defined by the user) (cf [8.0.7], [8.1.11]).*

**New CONTACT\_INIT:**

· *This key word makes it possible to do without artificial stiffnesses blocking the movements of body rigid (cf [8.0.8], [8.0.11]).*

**New CONTACT/COMPLIANCE:**

· *Introduction of a microphone-macro model for the interface of contact (effect of roughness to the microscopic scale) (cf [8.1.13]).*

**Key COURTEOUS Mr.**

**:**

**U4.01.04-A Page**

**: 4/8**

**New CHAMNO\_IMPO:**

· *Permet to take the contents of a CHAM\_NO like second member of the linear relation (cf [8.0.8]).*

**New ELIM\_MULT:**

· *If one wishes to bind several grids between them (key word LIAISON\_MAIL), one eliminate the redundant conditions now in order to avoid obtaining null pivots with moment of resolution (ELIM\_MULT='NON'). If in certain particular cases, one does not want not to eliminate these conditions, one can modify the default value (cf [8.0.3]).*

**New LIAISON\_CYCL:**

· *Application of cyclic condition of symmetry with dephasing (cf [8.0.8]).*

**Removed PRESSION\_CALCULE:**

· *EVOL\_CHAR makes the same thing and accepts other types of fields (cf [8.1.19]).*

### **Removed VERI\_DDL:**

- *The inexpensive checking is henceforth systematic (cf [8.1.19]).*

### **1.3.4 AFFE\_MATERIAU**

#### **New AFFE\_VARC:**

- *The variables of orders are now provided in AFFE\_MATERIAU and either in the operators of resolution DYNA\_NON\_LINE/STAT\_NON\_LINE (cf [8.1.4]).*

### **1.3.5 AFFE\_MODELE**

#### **New modelings PLAN\_ELDI, PLAN\_JOINT, AXIS\_ELDI, AXIS\_JOINT:**

- *XXX\_JOINT replaces to distinguish the elements JOINT from the elements with internal discontinuity ELDI (cf [8.0.18]).*

#### **New modelings:**

- *These modelings known as “selective” rest on a diagram of integration at the tops for the terms of the capacitive type, and at the points of Gauss for the terms of the diffusive type (cf [8.1.10]).*

### **1.3.6 CALC\_ELEM**

#### **Removed DURT\_ELGA\_TEMP:**

- *Calculations are now carried out with nodes (DURT\_ELNO\_TEMP) (cf [8.0.14]).*

### **1.3.7 CALC\_FATIGUE**

#### **New COEFF\_PREECROU:**

- *This parameter makes it possible to take into account a préécrouissage in the criteria of MATAKE, DANG\_VAN\_MODI\_AC/AV and DOMM\_MAXI (cf [8.0.3]).*

### **1.3.8 CREA\_MAILLAGE**

#### **New CREA\_FISS:**

- *Permet to generate meshes QUAD4 (to associate it finite elements discontinuity) with to start from groups of nodes (cf [8.0.13], [8.0.18]).*

#### **New QUAD\_LINE:**

- *Transformation of quadratic meshes into linear meshes (cf [8.0.13]).*

### ***1.3.9 CALC\_FATIGUE***

***CRITERION = new "FATEMI\_SOCIE":***

***· Ajout of the criterion of Fatemi and Socie in elasticity and plasticity (cf [8.1.5]).***

### ***1.3.10 CALC\_FLUI\_STRU***

***New AMOR\_REDUIT\_CONN:***

***· Méthode of Connors for the analysis of the vibratory behavior of the tubes of Steam Generator (cf [8.1.1]).***

### ***1.3.11 CALC\_G\_LOCAL\_T/CALC\_G\_THETA\_T***

***OPTION = new "K\_G\_MODA":***

***· Calcul of the modal stress intensity factors (cf [8.1.17]).***

### ***1.3.12 CALC\_META***

***META\_INIT, META\_ELGA\_TEMP removed:***

***· Supposer that the families of points of integration are the same ones for metallurgical calculation and mechanical calculation was not very healthy. Calculations are now made with the nodes.***

***META\_INIT is thus replaced by META\_INIT\_ELNO and META\_ELGA\_TEMP is removed, META\_ELNO\_TEMP is calculated by defect (cf [8.0.14]).***

### ***1.3.13 CREA\_CHAMP***

***New EXTR/TABLE:***

***· Permet to create a field starting from data contained in a table (cf [8.1.17]).***

### ***1.3.14 BEGINNING/CONTINUATION***

**ERROR new:**

· Permet to raise a Python exception instead of stopping on the level of FORTRAN (useful only for particular macro-orders) (cf [8.1.20]).

**New IMPR\_MACRO:**

· Permet to choose the view of the orders launched by an macro-order which is now decontaminated by defect (cf [8.1.13]).

**New RESERVE\_CPU:**

· Permet to ensure itself to have a minimum of time for the last stages of calculation (closing of the base, transfer of the results) (cf [8.0.13]).

**1.3.15 DEFI\_BASE\_MODAL**

**New ORTHO\_BASE:**

· Permet réorthogonaliser a modal base obtained by concatenation of several bases, the colinéaires modes can be eliminated by EXTR\_MODES (cf [8.1.7]).

**Instruction manual**

**U4.0- booklet: Use of the orders**

**HT-62/06/004/A**

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U4.01.04-A Page**

**: 6/8**

**1.3.16 DEFI\_FISS\_XFEM**

**CONTACT, INTEGRATION new:**

· Modélisation of the contact on the lips of the crack with the method continues (cf [8.0.6]) and choice of the method of integration to the nodes on the facets of contact (cf [8.1.7]).

### ***New RAYON\_ENRI:***

- *Permet to define a ray delimiting the zone of enrichment of the nodes in bottom of crack (cf [8.1.19]).*

### ***New ALGO\_LAGR:***

- *Sélection of the algorithm of choice of the space of Lagranges for the contact with X-FEM (cf [8.1.19]).*

### ***1.3.17 DEFI\_FLUI\_STRU***

#### ***CSTE\_CONNORS, RHO\_TUBE, NB\_CONNORS new:***

- *Méthode of Connors for the analysis of the vibratory behavior of the tubes of Steam Generator (cf [8.1.1]).*

### ***1.3.18 DEFI\_GROUP***

#### ***New DETR\_GROUP\_MA/DETR\_GROUP\_NO:***

- *Permettent to destroy existing groups, one can if need be create groups of same names (cf [8.1.6]).*

### ***1.3.19 DEFI\_MATERIAU***

#### ***RUPT\_FRAG, RUPT\_FRAG\_FO new:***

- *Définition of the parameters of the law of Barenblatt (tenacity, critical stress and jump of displacement) function of the temperature (cf [8.0.1]).*

#### ***LEMAITE\_IRRA, LMARC\_IRRA, GRAN\_IRRA\_LOG replace GRAN\_IRRA, FLU\_IRRA:***

- *Définition of the parameters of the various laws which one found before under the name ASSE\_COMBU (cf [8.0.8]).*

#### ***New GATT\_MONERIE:***

- *Nouvelle law of élasto-viscoplastic thermomechanics of the fuel (cf [8.0.16]).*

#### ***New BETON\_REGLE\_PR:***

- *Lawful Loi of concrete known as “right-angled parabola” (cf [8.0.17]).*

#### ***New HOEK\_BROWN:***

- *Loi of behavior of Hoek-Brown modified for the rock mechanics analysis (cf [8.1.1]).*

#### ***CABLE modification:***

- *The elastic parameters must be provided under key word ELAS (cf [8.1.17]).*

### ***1.3.20 DYNA\_NON\_LINE***

*See STAT\_NON\_LINE.*

### ***1.3.21 EXTR\_MODES***

***New SEUIL\_X/\_Y/\_Z:***

***· Permet to select the modes on a directional criterion (cf [8.1.17]).***

***Instruction manual***

***U4.0- booklet: Use of the orders***

***HT-62/06/004/A***

:

U4.01.04-A Page

: 7/8

### **1.3.22 GENE\_MATR\_ALEA**

**New MATR\_MOYEN:**

- Permet to generate a random *macr\_elem\_dyna* starting from an average value (cf [8.1.8]).

### **1.3.23 IMPR\_GENE**

**FORMAT, UNIT moved:**

- Was before under the key word factor *GENE* (cf [8.0.21]).

### **1.3.24 IMPR\_RESU**

**PART new:**

- Permet selection the real or imaginary part during the impression of complex fields (cf [8.1.1]).

**GROUP\_MA, MESH, GROUP\_NO, NODE new:**

- Sélection of topological entities added for format *MED* (cf [8.1.13]).

### **1.3.25 LIRE\_RESU**

**New POSI\_AMOR:**

- With format *IDEAS (unv)*, makes it possible to recover reduced damping (cf [8.1.17]).

### **1.3.26 MACR\_CABRI\_MAIL**

**Removed FILE:**

- Was not used any more (cf [8.0.6]).

### **1.3.27 MACR\_LIGN\_COUPE**

**LIGNE\_COUPE/new VECT\_Y:**

- Permet to define a local reference mark for postprocessing (cf [8.1.6]).

### **1.3.28 MACR\_RECAL**

**GRAPH/new FORMAT:**

- Permet to produce the curves with the format Xmgrace or Gnuplot (cf [8.1.22]).

### **1.3.29 MECA\_STATIQUE**

**NUME\_COUCHE, NIVE\_COUCHE, ANGLE and PLAN removed:**

- These key words were used for the calculation of certain options which are not calculated any more by

**MECA\_STATIQUE but CALC\_ELEM/CALC\_NO (cf [8.0.5]).**

### **1.3.30 MODI\_MODELE\_XFEM**

**New CRITERION:**

- Permet to remove the ddl jump to avoid a bad conditioning of the matrix (cf [8.1.7]).

**Instruction manual**

**U4.0- booklet: Use of the orders**

**HT-62/06/004/A**

### **1.3.31 POST\_K1\_K2\_K3**

### ***New SYME\_CHAR:***

- *Permet to take into account the symmetry of modeling in the calculation of the factors of intensity of constraint (cf [8.0.6]).*

### ***1.3.32 PROJ\_CHAMP***

#### ***New PROL\_ZERO:***

- *Permet to prolong the fields projected by zero where the initial field is not defined (cf [8.1.4]).*

### ***1.3.33 STAT\_NON\_LINE***

#### ***Removed VARI\_COMM:***

- *The variables of orders are provided in AFFE\_MATERIAU (cf [8.1.4]).*

#### ***New POSTING:***

- *Personnalisation of the posting of the table of convergence (cf [8.1.11]).*

### ***1.3.34 TEST\_FONCTION***

#### ***New VALE\_ABS:***

- *To test the absolute value of a result (cf [8.1.1]).*

### ***1.3.35 TEST\_RESU***

#### ***New RESU\_GENE:***

- *To test the concepts resu\_gene (cf [8.0.19]).*

#### ***New VALE\_ABS:***

- *To test the absolute value of a result (cf [8.1.1]).*

### ***1.3.36 TEST\_TABLE***

#### ***New VALE\_ABS:***

- *To test the absolute value of a result (cf [8.1.1]).*

***3 Operands***

***3.1 Word***

***key***

***UNIT***

***UNIT = num***

*Logical number of unit associated a file on which the impressions will be directed. One will defer to order **DEFI\_FICHER** [U4.12.03].*

### **3.2 Word**

*key*

**CONCEPT**

**I**

**CONCEPT =**

*Interrogation on the names of concepts and their type already created and present in the base of data “TOTAL” at a given moment of an execution or concepts which remain to be created or the unit.*

#### **3.2.1 Operand**

**NAME**

*NAME = list of the names of concepts requested*

.

*lnom list of names of concepts, whose one wishes information,*

.

*star “\*” to ask for the list of all the concepts (“\*” cannot be used in one list lnom).*

#### **3.2.2 Operand**

**OPTION**

*OPTION = option of edition of concept.*

**“TO CREATE”**

:

*one obtains the list of the concepts already created,*

**“A\_CREER”**

:

*one obtains the list of the concepts to be created,*

**“TOUT\_TYPE”**

*: to obtain the two preceding options simultaneously.*

### **3.3 Word**

*key*  
*TYPE\_ELEM*

*I TYPE\_ELEM*

=

*Impression of the whole of the couples (type\_element, option) available in the version used.*

### *3.3.1 Operand*

*INTEL*

*INTEL =*

*“YES”*

*: impression of the names of the objects created at the time of the initialization of all type\_element,*

*“NOT”*

*: nothing for this impression.*

*In both cases “YES”, “NOT”, one prints:*

.

*the number of options,*

.

*the number of type\_element,*

*a list of the form: phenomenon, modeling, type\_element, option, number of routine YOU (numero\_te), it gives all possible elementary calculations. If numéro\_te is worth -1, calculation is theoretically possible, but is not established.*

.

*a summary of type\_element: for each type\_element, one prints the number calculated options,*

.

*a summary of the options: for each option, one prints the number of type\_element who calculates it.*

***Instruction manual***

***U4.0- booklet: Use of the orders***

**Document: U4.03.01**

***Titrate and subtitles of a produced concept***

***1 Goal***

***To define a title or a subtitle during the execution of an order Aster.***

***The title and under title when they are envisaged by the order are:***

***.  
that is to say defined by defect,***

***.  
that is to say composed by the user.***

***In this last case the user has a certain number of tools allowing him to compose sound titrate or its subtitle.***

***The title is attached to the structure of data produced by an operator.***

***The titles of the modified concepts are piled up.***

***The composition of a title is possible since the operator has a single-ended spanner word TITRATES.***

***The awaited argument is a list of texts (l\_Kn).***

***The text provided by the user is used just as it is; in particular, there is no implicit conversion tiny/capital.***

***The subtitle makes it possible to add comments at the time of an impression by a procedure.***

***The subtitle exists only the time of the procedure and thus must be reconstituted with each call to procedure, in particular if that Ci is re-used in CONTINUATION. It is thus not attached to a concept.***

***The composition of a subtitle is possible since the procedure has the single-ended spanner word SOUS\_TITRE (possibly under a key word factor). It is thus not attached to a concept.***

***The awaited argument is a list of texts (l\_Kn).***

***The text provided by the user is used just as it is; in particular, there is no implicit conversion tiny/capital.***

***Composition of a title or a subtitle***

***2.1***

***tools***

***As we said, the user lays out of named tools “demons” allowing to integrate certain information with the title; these “demons” will seek corresponding information dynamically.***

***Examples of “demons”:***

***&date***

***return the date of execution,***

***&heure***

***return the hour of execution,***

***&RL***

***return information according to which it is necessary to go to the line in the composition title.***

***The complete list of the “demons” and their effects is provided in appendix.***

***Syntactic remark:***

.  
*the “demons” are preceded by the special character “&”,  
it is thus not recommended to use this special character in a title.*

*Simple example of title:*

*TITRATE = “My passage was carried out the &date with &heure”*

## 2.2

*Parameterized “demons”*

*The preceding examples of “demons” are known as simple or independent of the context, but there exists  
demons which are parameterized. Example:*

***&TYPE***

*return the type of a concept.*

*It is seen well that it is necessary to specify the name of the concept whose one wants to write the type:*

***&TYPE (my)***

*my*

*indicate a concept.*

*Action by defect:*

*If no argument is specified, one takes the concept produced by the operator like argument.*

## 2.3

*Titrate by defect*

*For any operator for whom the key word TITLE is planned, the default value is:*

***TITRATE =***

***(“ASTER &VERSION CONCEPT &RESULTAT”,***

***“CALCULATES &DATE A &HEURE OF THE &TYPE TYPE”***

***)***

*What gives for an operator who produces a concept named RIGIDITY and of type*

***MATR\_ASSE\_DEPL\_R:***

***ASTER 1.02.12 CONCEPT RIGIDITY CALCULATES THE 24/10/90 A 13:24: 51 OF TYPE  
MATR\_ASSE\_DEPL\_R***
