***Procedure BEGINNING***

## ***1 Goal***

***To allocate the resources memory, disc and files.***

***The execution consists of a whole of orders starting with BEGINNING and ending in END [U4.11.02], (see also the procedure CONTINUATION [U4.11.03]).***

***The order BEGINNING which is carried out, as of its reading by the Supervisor, carries out the tasks following:***

- .  
definition of the logical units of the files used in impression,***
- .  
definition of the characteristics of the data bases (managed by JEVEUX) and allowance of associated files,***
- .  
reading of the catalogues of the elements and the orders.***

***The apparently complex syntax of this procedure should not worry the user; its call with the operands by defect, sufficient in the majority of the cases, is: BEGINNING ()***

***The operands are to be used studies in the case of requiring a size of the files "bases of data " more important or to divert the various files on numbers of logical unit different from the numbers affected by defect.***

***The orders placed before BEGINNING, if they are syntactically correct, are ignored.***

**3 Operands**

**3.1 Operand**

**PAR\_LOT**

**PAR\_LOT**

**=**

**Mode of treatment of the orders:**

**“YES”:**

**(default option); the supervisor analyzes all the orders before in to ask the execution.**

**“NOT”:**

**after having analyzed an order the supervisor asks for his execution then passes to the analysis (and the execution) of the following order (treatment order by order).**

**3.2 Word**

**key**

**IMPR\_MACRO**

**IMPR\_MACRO**

=

*Authorize or not the postings produced by the macros in the file of message. Reading files of message can be painful when it contains the totality of the echoes of under orders generated by macro itself. By defect, only the echo of the orders explicitly called by the user in his command set will appear.*

### **3.3 Word**

*key*

**BASE**

**BASE**

=

*The functionality of this key word is to redefine the values of the parameters of the files direct accesses associated the “data bases” if one does not wish to use those fixed by defect.*

*Default values of the parameters associated with the data bases.*

**TOTAL**

**NMAX\_ENRE**

15728

**LONG\_ENRE**

100 K words

**LONG\_REPE**

2000

**BIRD**

**NMAX\_ENRE**

15728

Procedure BEGINNING

Date:

31/01/06

Author (S):

Key **J.P. LEFEBVRE**

:

U4.11.01-II Page

: 4/8

**Note:**

*The real size of the file is dynamic; it depends on the volume of information to store indeed. But this size is limited by the conditions of operating and one parameter preset among the values characterizing the platform. On the platform of reference TRU64 the maximum size is fixed at 12 Go. This value can be modified in placing an argument on the line of order of achievable behind the key word max\_base size where size is an actual value measured out of Mo.*

*On the platforms 32 bits, the maximum size is fixed at 2.047 Go (2 147.483.647), but the code manages several files to go beyond this limit when the parameter max\_base passed in argument.*

### **3.3.1 Operand**

#### **FILE**

**FILE**

=

*Reference symbol of the base considered.***3.3.2 Operands*****LONG\_ENRE/NMAX\_ENRE/LONG\_REPE****Definition of the parameters of the data base (files of direct access).*

/

/

***LONG\_ENRE***

=

***lenr****lenr is the length of the recordings in Kmots of the files of direct accesses used.***Note:***The manager of memory JEVEUX uses this parameter to determine two types of objects: the large objects which will be cut out in as much recordings that necessary, and the small objects which will be accumulated in a plug of the size of a recording before being discharged.*

/

***NMAX\_ENRE***

=

***nenr****nenr is the number of recordings per defect, this value is given with to start from LONG\_ENRE and an operating parameter on the platform of reference TRU64 fixed at 12 Go (12 884.901.888 bytes) for the maximum size of the file associated a data base, if this value were not modified by the use key word max\_base on the line of ordering of the achievable one.***Note:***Two operands LONG\_ENRE and NMAX\_ENRE must be used with precaution, a bad use which can lead to the brutal stop of program by saturation of the files of direct access. Coherence enters maximum size of the file and the value resulting from the product of both parameters LONG\_ENRE and NMAX\_ENRE is checked at the beginning of execution.*

/  
**LONG\_REPE**  
=  
*lrep*

*lrep is the initial length of the repertory (a maximum number of addressable objects by JEVEUX), it is managed dynamically by the manager of memory which extends size of the repertory and all the system objects progressively associated with needs.*

**Note:**

*The choice by the user to modify these various parameters, or to indicate a value behind the parameter max\_base determines in a final way certain characteristics of the TOTAL base which cannot be any more modified in CONTINUATION.*

**3.4 Word**

**key**

**CODE**

**CODE**

=

*Definition of a name for the whole of a study.*

### **3.4.1 Operand**

#### **NAME**

*NAME = name codes*

*Name of identification of the study, this name is with more than 8 characters.*

### **3.4.2 Operand**

#### **UNIT**

*UNIT = unitc*

*Number of the logical unit positive, associated the “condensed” writing of the orders.*

*Default value UNIT = 15.*

#### **Note:**

*This possibility is in particular used by all the tests of validation to preserve an image of the orders used by each one of them [VI.02.00].*

*It is possible to give a name to its study, without starting the impression of orders by indicating UNIT = 0.*

### **3.4.3 Operand**

#### **NIV\_PUB\_WEB**

*NIV\_PUB\_WEB = “INTRANET”*

*Level gauge of publication. Meaning that the test is only diffusable on internal network.*

*NIV\_PUB\_WEB = “INTERNET”*

*Indicate that the test is diffusable just as it is on the external network.*

*VISU\_EFICAS = "YES"*

*Indicate that the command file can be open without problem with tool EFICAS. It key word is primarily used for the tests and at ends of receipt of the news poured tool.*

*VISU\_EFICAS = "NOT"*

*Announce the presence of python source in the command file not allowing sound edition with tool EFICAS.*

### **3.5 Word**

*key*

**IMPRESSION**

*IMPRESSION*

=

*Definition of the logical units of the files used in impression.*

#### **3.5.1 Operand**

**FILE**

*FILE*

=

*List reference symbols of files.*

*Instruction manual*

*U4.1- booklet: Management*

*HT-62/06/004/A*

---

**Code\_Aster** ®

31/01/06

*Author (S):*

**Key J.P. LEFEBVRE**

:  
*U4.11.01-II Page*  
: 6/8

### **3.5.2 Operand UNIT**

*UNIT = uniti*

*Number of the logical unit associated the files of the list.*

*If uniti is negative or null, there is no impression on this (S) file (S).*

*By defect:*

#### **FILE UNIT**

*“ERROR” 9*

*“MESSAGE” 6*

*“RESULT” 8*

*“MED” 80*

*The definition of association file name, logical number of unit feeds the structure of data internal with the code which is generated by order DEF1\_FICHER [U4.12.03].*

### **3.6 Word**

*key*

#### **ERROR**

*ERROR =*

*Allows to recover an error of the <F> type to carry out a particular treatment, it mechanism was installed to check the emission of error message in the tests of not-regression of the code. It is also interesting to be able to recover the hand properly in some macros (Stanley or tools trades) without stopping brutally in fatal error.*

#### **3.6.1 Operand ERREUR\_F**

*ERREUR\_F*

*=*

*“ABORT” the behavior of the code is unchanged and the code stops by printing one*

*increase of error.*

*“EXCEPTION” one raises the exception aster.FatalError (code 20) and one returns to standard behavior in the event of error (“ABORT”)*

### **3.7 Word**

**key**

**DEBUG**

*DEBUG*

=

*Option of débogage (reserved for the developers and the maintenance of the code).*

#### **3.7.1 Operand**

**JXVERI**

*JXVERI*

=

*Allows to control the integrity of the segments of the memory between two executions of consecutive orders.*

*By defect the execution is carried out without “DEBUG”.*

#### **3.7.2 Operand**

**ENVIMA**

*ENVIMA = “TEST”*

*Allows to print in the file RESULT the values of the parameters preset in software package ENVIMA characterizing the machine [D5.01].*

*Instruction manual*

*U4.1- booklet: Management*

*HT-62/06/004/A*

: 7/8

### **3.7.3 Operand**

#### **JEVEUX**

**JEVEUX**

=

*Allows to activate the operating mode in debug of the manager of memory*

*JEVEUX: unloadings on disc not differed and assignment from the segments values with an indefinite value [D6.02.01].*

### **3.8 Key word**

#### **MEMORY**

*Allows to modify the mode of management of the memory. During the allowance in memory of a segment values, it is possible is to carry out a search for place by causing unloadings on disc (MANAGEMENT = "COMPACTS"), which makes it possible to use less memory capacity but with*

*price of many accesses disc, is to seek in a priority way the free zones or correspondent with accesses in reading alone (MANAGEMENT = "FAST").*

#### **3.8.1 Operand**

##### **MANAGEMENT**

**MANAGEMENT =**

*"COMPACT": allows to activate the mode of most sparing memory allocation in total place.*

*“FAST”*: allows to activate the mode of memory allocation privileging a fast access.

### **3.8.2 Operand**

#### **TYPE\_ALLOCATION**

*TYPE\_ALLOCATION* = *ty*

- 1: standard management of memory, one does not distinguish the objects to be allocated,*
- 2: the systems objects of collection are allocated at the end of the zone memory in order to avoid to scatter the latter and to too much split the zones likely to accomodate the large one objects,*
- 3: even standard of allowance that previously, but applying to a criterion of size of objects,*
- 4: the zone memory is partitionnée into two, a zone is reserved for the allowance of small objects.*

### **3.8.3 Operand**

#### **CUT**

*CUT* = size in words (unit of addressing in entirety) defining the small objects used for one type of allowance 3 or 4.

### **3.8.4 Operand**

#### **PARTITION**

*PARTITION* = relationship between the size of the zone memory used for the allowance of the “large” objects and total zone.

*This zone is located at the end of the segmentation, the systems objects specific to JEVEUX are allocated in the partition reserved for the “small” objects.*

#### **Note:**

*If one of the partitions is saturated, one returns to a mode of standard management of the memory (TYPE\_ALLOC = 1).*

*Date:*

*31/01/06*

*Author (S):*

*Key J.P. LEFEBVRE*

*:*

*U4.11.01-II Page*

*: 8/8*

### **3.8.5 Operand**

#### **TAILLE\_BLOC**

*This key word, formerly placed under SOLVEUR in the total orders, is used to define cut blocks of the matrix.*

*TAILLE\_BLOC =*

*One can choose the size of the blocks of the matrix of rigidity (tbloc). This size is given in kiloR8 (1 kiloR8 = 1024 realities). This parameter influences the number of operations of input/output and thus over the time of assembly and resolution. By defect this value is fixed at 800 kiloR8, that is to say 8 recordings per defect on the file of direct access associated base JEVEUX.*

### **3.9 Key word**

#### **RESERVE\_CPU**

*Allows to reserve a share of the time CPU allotted to the job to finish the execution properly in case of stop for lack of time CPU detected by an order Aster. This mechanism is not useful that in the case of an execution batch of Code\_Aster. The value of this reserve can be indicated in absolute value or in the form of a percentage of total time CPU. This value is limited by the value of the key word LIMITS.*

#### **3.9.1 Operand**

##### **VALE**

*Value expressed in seconds withdrawn from the total time CPU, over which certain orders total bases itself to stop the execution properly.*

#### **3.9.2 Operand**

##### **PERCENTAGE**

*Percentage withdrawn from the total time CPU, over which certain total orders is based for to stop the execution properly.*

### **3.9.3 Operand LIMIT**

*Maximum value of the reserve of time, being worth by defect 180 seconds.*

### **4 Example of use**

*The standard use of this procedure is:*

= “YES”,  
[DEFECT]  
“NOT”,

*Cause the impression in the file defined under the key word **FILE** of information relative to contained of the whole of the structures of data result stored in the **TOTAL** base.*

**Note:**

*The use of this key word can increase in a consequent way the execution time of order **FINE**, it is thus advised to modify the default value when one carries out calculations generating of important quantities of data by their diversity.*

### **3.4 Operand UNIT**

**UNIT**  
= *numfic*

*Allows to redefine the logical unit of impression of the information produced by **INFO\_RESU**.*

### **3.5 Operand FICHER\_HDF**

**FORMAT\_HDF** = “YES”

*Allows to write the **TOTAL** base in a file with format **HDF**. The base could then be rebuilt starting from objects **JEVEUX** stored in the file, this file can be created on a different platform (operating system, platform 32 or 64 bits). Characteristics original base will be read again in the file and the base rebuilt with identical (one for example the length of the recordings will preserve).*

*The user will be able to then read again either file HDF, or base JEVEUX.*

### ***Principle of operation***

*This procedure affects, moreover, the resources memory necessary to the continuation of calculation.*

*The operands of the order are homologous with those of the procedure BEGINNING [U4.11.01]. They allow to specify certain resources assigned to the new execution.*

*The study carried out previously continues with a whole of orders starting with CONTINUATION and ending in END [U4.11.02].*

*Orders placed before CONTINUATION (except obviously BEGINNING) or after END, if they are syntactically correct, are ignored.*

*The procedure CONTINUATION which is carried out, as of its reading by the supervisor, carries out the tasks following:*

- *definition of the logical units of the files used in impression,*
- *allowance of the files associated with the data bases managed by JEVEUX,*
- *reading of the catalogues of orders but not of the catalogues of the elements which were*

*recopied on the basis of data during the first execution.*

*The operands are to be used to divert the various files on numbers of logical unit different from the numbers affected by defect or to adjust certain parameters of files.*

*The simple concepts of python (of variable type) created during a preceding execution are preserved in a file associated with base JEVEUX (pickle.1). during the execution of the procedure CONTINUATION these concepts are regenerated and can thus be used under the name under which they have summer created.*

## **4 Operands**

*The operand PAR\_LOT and words key IMPRESSION and DEBUG are identical to those of the procedure BEGINNING [U4.11.01].*

*The key word BASE is different for the procedure CONTINUATION.*

### **4.1 Operand PAR\_LOT**

*PAR\_LOT*

=

*Mode of treatment of the orders:*

*“YES”:*

*(default option); the supervisor analyzes **all the** orders before in to ask the execution.*

*“NOT”:*

*after having analyzed an order the supervisor asks for his execution then pass to the analysis (and the execution) of the following order (treatment order by order).*

### **4.2 Word**

*key*

*IMPR\_MACRO*

*IMPR\_MACRO*

=

*Authorize or not the postings produced by the macros in the file of message. Reading*

*files of message can be painful when it contains the totality of the echoes of under orders generated by macro itself. By defect, only the echo of the orders explicitly called by the user in his command set will appear.*

*Instruction manual*

*U4.1- booklet: Management*

### **4.3 Word**

**key**

**BASE**

BASE

=

*The functionality of this key word is to redefine the values of the parameters of the files of access direct associated the "data base" if one does not wish to use those fixed by defect.*

*In CONTINUATION mode, the various characteristics of the TOTAL base cannot be any more modified.*

*Default values of the parameters associated with the data bases*

**BIRD**

**NMAX\_ENRE 15728**

**LONG\_ENRE**

*100 K words*

**LONG\_REPE 2000**

**LOCAL**

**NMAX\_ENRE**

**512**

**LONG\_ENRE**

*100 K words*

**LONG\_REPE 2000**

*The word is worth 8 bytes out of platform 64 bits under TRU64 and IRIX 64, 4 bytes on platform*

*32 bits under SOLARIS, HP-UX and WINDOWS-NT, LINUX.*

*Under TRU64, the procedure CONTINUATION, with the default values, will allocate a file of access direct of with more the 15728 recordings of 100 Kmot (K is worth 1024) for the “VOLATILE” base.*

**Note:**

*The real size of the file is dynamic; it depends on the volume of information to store indeed. But this size is limited by the conditions of operating and one parameter preset among the values characterizing the platform. On the platform of reference TRU64 the maximum size is fixed at 12 Go. This value perhaps modified in placing an argument on the line of order of achievable behind the key word max\_base size where size is an actual value measured out of Mo.*

**4.3.1 Operand  
FILE**

*FILE*

=

*Only the parameters of the data bases “LOCAL” and “VOLATILE” can be redefined.*

**4.3.2 Operands**

***LONG\_ENRE/NMAX\_ENRE/LONG\_REPE***

*Definition of the parameters of the data base (files of direct access).*

/

|

*LONG\_ENRE*

=

*lenr*

*lenr is the length of the recordings in Kmots of the files of direct accesses used.*

**Note:**

*The manager of memory JEVEUX uses this parameter to determine two types of objects: the large objects which will be cut out in as much recordings that necessary, and the small objects which will be accumulated in a plug of the size of a recording before being discharged.*

*Instruction manual*

*U4.1- booklet: Management*

*Author (S):*

**Key J.P. LEFEBVRE**

:

*U4.11.03-II Page*

: 6/10

/

*NMAX\_ENRE*

=

*nenr*

*nenr is the number of recordings per defect, this value is given with to start from LONG\_ENRE and an operating parameter under IRIX 64 fixed at 12 Go (12 884.901.888 bytes) for the maximum size of the file associated with a base with data.*

**Note:**

*Two operands LONG\_ENRE and NMAX\_ENRE must be used with precaution, a bad use which can lead to the brutal stop of program by saturation of the files of direct access. Coherence enters maximum size of the file and the value resulting from the product of both parameters LONG\_ENRE and NMAX\_ENRE is checked at the beginning of execution.*

/

*LONG\_REPE*

=

*lrep*

*lrep is the initial length of the repertory (a maximum number of addressable objects by*

*JEVEUX*), it is managed dynamically by the manager of memory which extends size of the repertory and all the system objects progressively associated with needs.

#### **4.4 Word**

**key**

#### **IMPRESSION**

*IMPRESSION*

=

*Definition of the logical units of the files used in impression.*

#### **4.4.1 Operand**

#### **FILE**

*FILE*

=

*List reference symbols of files.*

#### **4.4.2 Operand**

#### **UNIT**

*UNIT = uniti*

*Number of the logical unit associated the files of the list.*

*If uniti is negative or null, there is no impression on this (S) file (S).*

*By defect:*

**FILE**

**UNIT**

“ERROR” 9

“MESSAGE” 6

“RESULT” 8

“MED” 80

*The definition of association file name, logical number of unit feeds the structure of data internal with the code which is generated by order `DEFI_FICHER` [U4.12.03].*

#### **4.5 Word**

**key**

#### **ERROR**

**ERROR =**

*Allows to recover an error of the <F> type to carry out a particular treatment, it mechanism was installed to check the emission of error message in the tests of not-regression of the code. It is also interesting to be able to recover properly hand in some macros (Stanley or tools trades) without stopping brutally in fatal error.*

*Instruction manual*

*U4.1- booklet: Management*

*HT-62/06/004/A*

---

**Code\_Aster** ®

*Version*

*Titrate:*

*Procedure CONTINUATION*

*Date:*

31/01/06

*Author (S):*

**Key J.P. LEFEBVRE**

:

*U4.11.03-II Page*

: 7/10

#### **4.5.1 Operand**

**ERREUR\_F**

**ERREUR\_F =**

*“ABORT” the behavior of the code is unchanged and the code stops by printing one increase of error.*

*“EXCEPTION” one raises the exception aster.FatalError (code 20) and one returns to standard behavior in the event of error (“ABORT”)*

#### **4.6 Word**

**key**

**DEBUG**

**DEBUG =**

*Option of débogage (reserved for the developers and the maintenance of the code).*

#### **4.6.1 Operand**

##### **JXVERI**

*JXVERI*

= “YES”

“NOT”

*Allows to control the integrity of the memory between two executions of orders consecutive. By defect the execution is carried out without “DEBUG”.*

#### **4.6.2 Operand**

##### **ENVIMA**

*ENVIMA = “TEST”*

*Allows to print in the file “RESULT” the values of the parameters preset in software package ENVIMA characterizing the machine [D5.01].*

#### **4.6.3 Operand**

##### **JEVEUX**

*JEVEUX = “YES”*

“NOT”

*Allows to activate the operating mode in debug of the manager of memory JEVEUX: unloadings on disc not differed and assignment from the segments of values to a value indefinite [D6.02.01].*

#### **4.7 Word**

*key*

##### **MEMORY**

*Allows to modify the mode of management of the memory. During the allowance in memory of a segment values, it is possible is to carry out a search for place by causing unloadings on disc (MANAGEMENT = "COMPACTS"), which makes it possible to use less memory capacity but with price of many accesses disc, is to seek in a priority way the free zones or correspondent with accesses in reading alone (MANAGEMENT = "FAST").*

#### **4.7.1 Operand MANAGEMENT**

*MANAGEMENT =*

*"COMPACTS"*

*:*

*allows to activate the mode of most sparing memory allocation in total place*

*"FAST": allows to activate the mode of memory allocation privileging a fast access*

#### **4.7.2 Operand TYPE\_ALLOCATION**

*TYPE\_ALLOCATION = ty*

- 1: standard management of memory, one does not distinguish the objects to be allocated,*
- 2: the systems objects of collection are allocated at the end of the zone memory in order to avoid to scatter the latter and to too much split the zones likely to accomodate the large one objects,*
- 3: even standard of allowance that previously, but applying to a criterion of size of objects,*
- 4: the zone memory is partitionnée into two, a zone is reserved for the allowance of small objects.*

U4.11.03-II Page

: 8/10

### **4.7.3 Operand CUT**

*CUT = size in words (unit of addressing in entirety) defining the small objects used for a type of allowance 3 or 4.*

### **4.7.4 Operand PARTITION**

*PARTITION = relationship between the size of the zone memory used for the allowance of the large objects and total zone.*

*This zone is located at the end of the segmentation, the systems objects specific to JEVEUX are allocated in the partition reserved for the “small” objects.*

#### **Note:**

*If one of the partitions is saturated, one returns to a mode of standard management of the memory (TYPE\_ALLOC = 1).*

### **4.7.5 Operand TAILLE\_BLOC**

*This key word, formerly placed under SOLVEUR in the total orders, is used to define cut blocks of the matrix.*

*TAILLE\_BLOC =*

*One can choose the size of the blocks of the matrix of rigidity (tbloc). This size is given in kiloR8 (1 kiloR8 = 1024 realities). This parameter influences the number of operations of input/output and thus over the time of assembly and resolution. By defect this value is fixed at 800 kiloR8, that is to say 8 recordings per defect on the file of direct access associated base JEVEUX.*

## **4.8 Key word**

### **RESERVE\_CPU**

*Allows to reserve a share of the time CPU allotted to the job to finish the execution properly in case of stop for lack of time CPU detected by an order Aster. This mechanism is not useful that in the case of an execution batch of Code\_Aster. The value of this reserve can be indicated in absolute value or in the form of a percentage of total time CPU. This value is limited by the value of the key word LIMITS.*

### **4.8.1 Operand**

#### **VALE**

*Value expressed in seconds withdrawn from the total time CPU, over which certain orders total bases itself to stop the execution properly.*

### **4.8.2 Operand**

#### **PERCENTAGE**

*Percentage withdrawn from the total time CPU, over which certain total orders is based for to stop the execution properly.*

### **4.8.3 Operand**

#### **LIMIT**

*Maximum value of the reserve of time, being worth by defect 180 seconds.*

*Instruction manual*

## **4.9 Word**

**key**

**FORMAT\_HDF**

*FORMAT\_HDF = "YES"*

*Allows to read again a TOTAL base safeguarded in a file with format HDF (cf orders END [U4.11.02]). The base is then rebuilt starting from objects JEVEUX stored in the file, this file can be built on a different platform (operating system, punt form 32 or 64 bits). The characteristics of the original base are read again in the file and the base is rebuilt with identical (one preserves for example the length of the recordings).*

*The file associated with the TOTAL base with format HDF is named bhdf.1 in the repertory of execution of the code.*

## **5 Example of use**

*The standard use of this procedure is:*

*CONTINUATION ()*

*To make an execution with a "VOLATILE" base with a record length of 400 Kmots:*

*CONTINUATION  
(BASE = \_F (FILE = "VOLATILE", LONG\_ENRE = 400),)*

*of*  
*DEFI\_FICHER*

*The inputs/outputs on the ASCII files since Code\_Aster are carried out for the majority, with the assistance instructions FORTRAN using the concept of unit logical, it is a variable entirety from 1 to 99*

*associated*

*assistance of an instruction of the “open” type to a file. By defect this number xx is associated the name*

*fort.xx, but it is possible to associate it an unspecified file name. The logical number of unit is used in the interface of access to the code astk to recopy the exit and input files.*

*In the command file Aster various operators carrying out of the readings or the writings admit the key word UNIT like argument.*

*Several logical units are reserved by the code at the time of the phase of initialization, they are associated the following files, it is in general not allowed to modify them.*

*· 6 :*

*MESSAGE*

*· 8 :*

*RESULT*

*· 9 :*

*ERROR*

*· 80: MED*

*The key word IMPRESSION of the procedure BEGINNING [U4.11.01] or the procedure CONTINUATION [U4.11.03]*

*at the head command file can define associations between imposed names of files and their logical units FORTRAN.*

*The user can wish to add or modify associations using the procedure*

*DEFI\_FICHER to use for example new file names, to print some*

*results or to differently gather them in files. Procedure DEFI\_FICHER allows in*

*in addition to directly indicating the file of the ASCII type which will be associated the specified logical unit. It*

*can be specified either by a name in absolute (limited to 255 characters) if the file is localised on machine, is by a relative name in an agreed repertory (. /REPE\_IN or ./REPE\_OUT) when the interface takes care of the distant and total transfer of the whole of the files located under the repertory*

*(repe type in astk). OPEN named FORTRAN is then carried out on the files of the ASCII type. order makes it possible of more than position either file at the head, or at the end of the file.*

*The code manages in-house a structure of data gathering the unit of associations unit logic standard file name of file - type of access.*

## *4 Operands*

*The modifications of association unit logic-name of file relates to the output files and of entry.*

### *4.1 Operand*

## **ACTION**

### **ACTION = “TO ASSOCIATE”**

*The logical number of unit is associated, when that is allowed, the name defined behind the key word FILE if it is indicated, with the name fort.xx if not.*

*It is not possible to redefine associations of the logical numbers 6 and 9.*

### **ACTION = “TO RELEASE”**

*The logical number of unit is released, it is not more possible to use this number of unit, the file associated, when it is of ASCII type, is the subject of an order of closing using the instruction FORTRAN CLOSED. It then becomes possible to re-use the logical number of unit. This mechanism is*

*essential if one wants to be able D-to immediately exploit the contents of the associated file in command file in progress, indeed the buffers must be completely emptied and it file must be able to be accessible, possibly at the time of a call to a software since one order python of the os.system type.*

*Instruction manual*

*U4.1- booklet: Management*

*Author (S):*

*J-P. Key LEFEBVRE*

*:*

*U4.12.03-B1 Page:*

*4/6*

### **ACTION = “TO RESERVE”**

*This type of action is used in the macros orders and makes it possible to avoid the conflicts of number of logical unit between FORTRAN and python.*

*The logical number of unit is associated, when that is allowed, the name defined behind the key word FILE if it is indicated, with the name fort.xx if not. There is no instruction of the OPEN type*

*carried out, with load for the macro order to carry out the various actions necessary.*

## **4.2 Operand FILE**

**FILE = nomfic**

*Physical name of the file (255 characters) which one wishes to associate a logical unit. This file will be created under the repertory of execution of the code, but one can indicate a name directly of file (respecting conventions UNIX) in the repertory of the user. Under the repertory of execution, it is possible to use an additional level of tree structure of name conventional REPE\_IN (data files) or REPE\_OUT (files of results) recognized by the interface of access to the code ask. This name must be placed between quotes. Although they are not associated a logical unit by an OPEN order FORTRAN, binary files (for example MED) can be treated with this mechanism, it is necessary nevertheless to specify the type of access NEW or OLD to activate the recopy (by a call system since the code) since the data directory or towards the repertory in result.*

*When the operand misses, it is by defect the file name fort.ul where ul is the number of unit which is associated the logical unit definite behind UNIT.*

*For the file of the ASCII type, an OPEN instruction FORTRAN is carried out on the name associated with the logical unit.*

## **4.3 Operand UNIT**

**UNIT = numul**

*Number of logical unit associated, its value for the ASCII file opened by instructions is ranging between 1 and 99 included.*

*It is possible to re-use an already affected number but in this case it is necessary to take the precaution*

*to release this last before. Certain numbers D `units logical cannot be redefined since the orders Aster, they are the numbers 6 and 9 which are respectively allocated with files MESSAGE, and ERROR.*

*This number can be used then in all the Aster orders which have the operand UNIT (IMPR\_RESU, IMPR\_TABLE, IMPR\_COURBE, etc).*

*The operand UNIT can sometimes be omitted, it is then the code which will choose to affect a number, according to the availabilities, it is then necessary imperatively to specify the operand FILE, the code*

*then in-house load to associate the logical number of unit and the associated file. It is then possible to recover a whole value at exit of the operator.*

#### **4.4 Operand TYPE**

**TYPE = "ASCII"**

*The file associated with the logical unit is of ASCII type.*

**TYPE = "BINARY"**

*The file associated with the logical unit is of binary type (not still used in the code).*

**TYPE = "FREE"**

*The file associated with the logical unit is of unspecified type within the meaning of FORTRAN, that allows*

*to manage in a more flexible way the access to the file, this type is primarily used for the access to files MED. The logical unit is not really used in this case, but that makes it possible to have convention of name fort.ul on the file and being able to easily transmit it through the interface access to the code.*

:

U4.12.03-B1 Page:

5/6

#### **4.5 Operand ACCESS**

*Is used only in the case of the files of the ASCII type.*

*ACCESS = "NEW"*

*The file is opened and one positions at the head, a Fortan instruction of the type REWIND is carried out.*

*ACCESS = "OLD"*

*The file is opened and one positions just as it is.*

*ACCESS = "SUSPENDS"*

*The file is opened and one positions at the end of the file.*

#### **4.6 Operand INFORMATION**

*INFORMATION = inf*

*Allows to print in the file MESSAGE the list of the open logical units with order DEFI\_FICHER as well as the associated parameters. If INFORMATION = 1, it does not have there of impression.*

## 5

### ***Declaration in the interface of access to the code of the unit logic implemented in DEFI\_FICHIER***

*Generally the user will invite DEFI\_FICHIER in order to carry out postprocessings when it test the need to physically create several files of results according to the cases of loads, of the sizes, the steps or moments of evolution of calculation.*

*The user must declare the names physical of the files and the associated logical units. This declaration is carried out, in the interface ask before the launching of the completion of the work. It is necessary to add the files in the profile of study by selecting the **libr** type and to associate the number to them of logical unit selected.*

*The repe type is used in the interface ask to transmit or receive all the contents of one file directory, with load for the user to make call in the command file with DEFI\_FICHIER to carry out association with the logical number of unit. For convention the data files are transmitted in the repertory of nonroom REPE\_IN, them files in result are transmitted in the repertory of local name REPE\_OUT. In order DEFI\_FICHIER, the name placed behind FILE is form:  
./REPE\_IN/mon\_fichier.*

**U4.13.04-A Page**

**: 3/4**

## **3 Operands**

### **3.1 Operand**

**LISTE\_INFO**

**LISTE\_INFO = "CPU\_RESTANT"**

*Allows to recover time CPU remaining during the execution: it is the difference between affected time during the tender batch of the study, or the value of the time CPU spent on the line of order for an interactive execution and the value of spent time CPU.*

**LISTE\_INFO = "UNITE\_LIBRE"**

*Return the first number of logical unit available (by descending order from 99) to moment of L`call. This value, recovered in a variable python, can then have passed in argument of an order Aster. The numbers of logical unit are managed from order DEFI\_FICHER [U4.12.03] and are deposited within a structure of data intern with the code which establishes the link between the files and the numbers of units.*

**LISTE\_INFO = "ETAT\_UNITE"**

*Turn over a table containing information "OPEN" or "FIRM" indicating the state of the unit logic or of the associated file.*

### **3.2 Operand**

**UNIT**

**UNIT = num**

***Logical number of unit which one wants to know the state:***

***“OPEN”***: a file uses this number

***“FIRM”***: no file uses this number

### ***3.3 Operand***

#### ***FILE***

***FILE = name***

***File name, such as defined in the order DEFI\_FICHER [U4.12.03] which one wants to know the state:***

***“OPEN”***: this name is associated a logical unit and is used

***“FIRM”***: this name is associated no logical unit and the associated file is regarded as closed

### ***3.4 Operand***

#### ***TITRATE***

***TITRATE = title***

***Affected title with the structure of data counts associated. For more details to see [U4.03.01].***

### ***3.5 Operand***

#### ***INFORMATION***

***INFORMATION = 1***

***Operand unutilised for the moment.***

***Instruction manual***

***U4.1- booklet: Management***

***HT-66/05/004/A***

:

**U4.13.04-A Page**

**: 4/4**

#### **4 Remark**

*The accessible table since the command file python makes it possible to recover the value of time CPU remaining, which is a function of the orders carried out previously, but does not take account of time CPU spent in the processes called by EXEC\_LOGICIEL and of the calls system since python.*

#### **5 Example**

*# One carries out a loop from 1 to 10*

*for K in arranges (1,10):*

*#*

*# one calls one or more orders (AFFE\_CHAR\_MECA, STAT\_NON\_LINE, etc)*

*...*

*# one recovers time remaining in table TCPU*

*TCPU=INFO\_EXEC\_ASTER (LISTE\_INFO=' CPU\_RESTANT')*

*# one recovers the value of time in a variable python*

*valcpu=TCPU ["CPU\_RESTANT", 1]*

*# one tests this variable python, if it remains less than 5 S, one leaves buckle*

*yew valcpu < 5.0:*

*station-wagon*

*# one destroys the concept of the type counts, to be able the récréer with the following iteration.*

Operator *TO DESTROY*

Date:

19/01/05

Author (S):

Key **J.P. LEFEBVRE**

:

U4.14.01-F Page

: 4/4

#### **4 Example**

*% One creates a list of realities of name F*

*F = DEFI\_LIST\_REEL (...)*

*% One destroys the concept of name F*

*TO DESTROY (CONCEPT = \_F (NAME = F,))*

*% One can re-use the name F for another concept*

*F = DEFI\_FONCTION*

*( ... )*

#### **5 Remarks**

*This procedure must be used with prudence, indeed certain structures of data (field with node-classification, field by element-model, etc...) the ones are based on the others, it is thus dangerous to destroy the associated concept.*

*When a concept is removed, its name is destroyed space of names python and the jeveux objects related (prefixed by the name of the concept) are destroyed in the total base.*

*During calculations with the loops with great iteration count (parametric study...), it can be very advantageous to destroy the concepts not employed again from one iteration to another in order to preserve the size of the total base.*

7.4

Titrate:

Operator *LIRE\_MAILLAGE*

Date:

08/02/05

Author (S):

**J. Key PELLET**

:

*U4.21.01-H Page*

: 3/4

### **3 Operands**

#### **3.1 Operand**

##### **FORMAT**

*This key word is used to specify the format of the file to reading. Today 2 formats are available: "ASTER" and "MED".*

*The format "ASTER" is described in [U3.01.00]*

*Format "MED" is described in [U7.01.21.]*

#### **3.2 Operand**

##### **UNIT**

**UNIT =**

**I**

*Logical number of unit of the file grid. Unit 20 per defect.*

#### **3.3 Operand**

##### **NOM\_MED**

**NOM\_MED = *nomed***

*For a file with format "MED", one can give the name of the grid under which the grid has there recorded summer. By defect, one will seek it under the name of concept to create (my)*

### **3.4 Operand VERI\_MAIL**

**Key word VERI\_MAIL starts 3 checks on the grid:**

- .  
absence of orphan nodes,**
- .  
absence of meshes “in double”,**
- .  
absence of too flattened meshes.**

**If these checks are not satisfied, the code emits an alarm.**

**By defect (i.e. in the absence of key word VERI\_MAIL), the checks are made. If the user wants to avoid these checks, it will write:**

**VERI\_MAIL = \_F (VERIF = “NOT”),**

**A node is declared orphan if it does not belong to the connectivity of any mesh.**

**A mesh is declared “in double”, if 2 meshes (or more) have connectivities formed consequently list nodes.**

**The key word FLAT TINT = ap makes it possible to emit alarms when the grid contains meshes too much flattened.**

**The flatness of a mesh is defined like the Amin/Amax report/ratio where Amin and Amax are them lengths of stop shortest and longest of the mesh. The name of the meshes of which flatness is lower than ap will be printed on the file “MESSAGE”.**

**Other quality standards for the grid are available via order MACR\_INFO\_MAIL [U7.03.02].**

### **3.5 Operand ABS\_CURV**

**ABS\_CURV = \_F (ALL = “YES”),**

**Calculate a curvilinear X-coordinate for the whole of meshes SEG2 of the grid. One associates each mesh the curvilinear X-coordinate of the first and the second node in the direction of course.**

**This option is necessary, for example, to carry out a modal calculation for a tube with fluid external and intern, when the density of the external fluid is defined according to**

*the curvilinear X-coordinate.*

*N9*

*N1*

*N3*

*N5*

*N7*

*L*

*All the meshes of the grid must be of type “SEG2”.*

*The mesh origin is the first mesh met, during the reading of the file grid, not having that a consecutive mesh (mesh N1 N3).*

*The final mesh is the last mesh met in the direction of course having only one*

*consecutive mesh (mesh N4 N2).*

*If there is more than one way between the first and the last mesh, calculation is impossible.*

*The curvilinear X-coordinate is defined as the sum of the right-hand sides connecting the nodes:*

*K*

*for K meshes: S*

*K =*

*xi - xi-1*

*i=2*

### **3.6 Operand**

#### **INFORMATION**

#### **INFORMATION**

*=*

*/1, [DEFECT]*

**5/18**

**3 Operands**

**3.1**

**General information on the operands**

**This order in the same way treats the concepts of the grid type or skeleton. In continuation one will use the vocabulary “grid”.**

**This order makes it possible to define new groups of meshes (or groups of nodes) in one existing grid: one enriches the grid my.**

**The definition of a new group can be done in several ways:**

•  
*in extension: key words NETS or NODE,*

•  
*by Boolean operation on existing groups: intersection (INTERSEC), meeting (UNION) or difference (DIFFE),*

•  
*according to a geometrical criterion: meshes whose node belongs to a given sphere,...*

•  
*for the groups of nodes, by referring to existing groups of meshes.*

*group nodes thus definite contains all the nodes of the meshes of the group of meshes origin (key words TOUT\_GROUP\_MA and GROUP\_MA).*

*The operator treats initially key word CREA\_GROUP\_MA so that one can make use of the groups of meshes thus defined in key word CREA\_GROUP\_NO.*

*With each occurrence of a key word CREA\_GROUP\_MA (\_NO) one defines a new group named (word key NAME). This new group can then be re-used in the following occurrences to define new groups by intersection, meeting,...*

*Key words DETR\_GROUP\_MA and DETR\_GROUP\_NO make it possible “to destroy” groups of meshes or of nodes. The meshes and the nodes of these groups are not removed, they are only them definitions of the groups which are unobtrusive. These key words are useful for example in the loops python when one wants to create a group with each iteration of the loop: one starts by destroying this group then one recreates it under the same name. That avoids changing name of group with each iteration.*

### **3.2 Operand GRID**

*GRID = my*

*my is the name of the grid which one wants “to enrich”.*

### **3.3 Words**

*keys*

*DETR\_GROUP\_MA and DETR\_GROUP\_NO*

*These two key words factor make it possible to remove the definition of groups of meshes or nodes. These key words are sometimes necessary because the code stops in fatal error if one tries to create one*

*group whose name is already used. It is necessary to destroy the group before being able to re-use its name.*

*behavior of the two key words is similar and we will speak here only about DETR\_GROUP\_MA.*

**Syntax:**

**DETR\_GROUP\_MA=\_F (NOM= (gm1, gm2,...)),**

*The key word factor DETR\_GROUP\_MA is a priori répétable but it is never necessary because the word*

*key NAME makes it possible to indicate a list of names of groups to be destroyed (gm1, gm2,...).*

**Instruction manual**

**U4.2- booklet: Grid**

**HT-62/06/004/A**

---

**Code\_Aster ®**

**Version**

**8.2**

**Titrate:**

**Operator DEFI\_GROUP**

**Date:**

**31/01/06**

**Author (S):**

**J. Key PELLET**

**:**

**U4.22.01-H1 Page:**

**6/18**

*It is important to know that all the occurrences of key word DETR\_GROUP\_MA are treated front those of key word CREA\_GROUP\_NO because the objective of this key word is to be able to re-use the destroyed name. It*

*is also necessary to know that the destruction of a non-existent group does not involve any message of alarm.*

*These choices make it possible for example to make in a loop python:*

*for I in arranges (N):*

*DEFI\_GROUPE (reuse=MA, MAILLAGE=MA,*

*DETR\_GROUP\_MA=\_F (NAME ("GMI"),*

*CREA\_GROUP\_MA=\_F (NOM=' GMI',...*

*At the time of the first iteration, group "GMI" does not exist, one requires his destruction but any message of alarm is not transmitted.*

**Note:**

*As the destruction takes place at the beginning of the order, it is impossible to modify one group by calling only one upon `DEFI_GROUP`. For example, one cannot make “grow bigger” (in a loop) a group by adding a small group (b1) to him:*

*for I in arranges (N):*

*b1=nouveau group...*

*DEFI\_GROUP (reuse=MA, MAILLAGE=MA,*

*CREA\_GROUP\_MA=\_F (NOM=' tout', UNION= (“all”, “b1”),),)*

*To do that, `DEFI_GROUP` should be invited twice:*

*for I in arranges (N):*

*b1=nouveau group...*

*DEFI\_GROUP (reuse=MA, MAILLAGE=MA,*

*DETR\_GROUP\_MA=\_F (NOM=' tout2'),*

*CREA\_GROUP\_MA=\_F (NOM=' tout2', UNION= (“all”, “b1”),),)*

*DEFI\_GROUP (reuse=MA, MAILLAGE=MA,*

*DETR\_GROUP\_MA=\_F (NOM=' tout'),*

*CREA\_GROUP\_MA=\_F (NOM=' tout', UNION= (“tout2”, “b1”),),)*

### *3.4 Word*

*key*

*CREA\_GROUP\_MA*

*/CREA\_GROUP\_MA*

*An occurrence of this key word factor makes it possible to define a new group of meshes.*

#### *3.4.1 Operand*

*NAME*

*NAME = gma*

*One gives here the name (with “quotes”) of the new group of meshes.*

#### *3.4.2 Operand*

*NET*

*/MESH = lmail*

*This key word makes it possible to define the group of meshes in extension: the list of the meshes is given*

*the component.*

*Instruction manual*

*U4.2- booklet: Grid*

*HT-62/06/004/A*

---

*Code\_Aster* ®

*Version*

*8.2*

*Titrate:*

*Operator DEFI\_GROUP*

*Date:*

*31/01/06*

*Author (S):*

*J. Key PELLET*

*:*

*U4.22.01-H1 Page:*

*7/18*

*3.4.3 Operand*

*ALL*

*/ALL = "YES"*

*This key word makes it possible to define a group containing all the meshes of the grid.*

*3.4.4 Operand*

*INTERSEC*

*/INTERSEC = (gma1, gma2, gma3,...),*

*The new group of meshes will be obtained by taking all the meshes of gma1 which also belong to gma2, gma3,.... The order of the meshes remains that of gma1.*

*3.4.5 Operand*

*UNION*

*/*  
*UNION*  
*= (gma1, gma2, gma3,...)*

*The new group of meshes will be obtained by taking all the meshes of gma1, then in adding the meshes of gma2 which do not belong to gma1, then those of gma3 which belong neither to gma1 nor with gma2, etc*

### **3.4.6 Operand DIFFE**

*/DIFFE = (gma1, gma2, gma3,...)*

*The new group of meshes will be obtained by taking all the meshes of gma1 which do not belong to the other groups of the list. The order of the meshes remains that of gma1.*

### **3.4.7 Sub-group of an existing group : key words GROUP\_MA/POSITION/ NUME\_INIT/NUME\_FIN**

*One can create a new group of mesh by selecting certain meshes of an existing group.*

*1st possibility:*

*One creates a group of only one mesh by specifying by the key word POSITION the required mesh.*

*Example:*

```
CREA_GROUP_MA = _F (  
GROUP_MA = G1  
, POSITION = "INIT", NAME = G11)
```

*Group G11 contains the 1st mesh of the G1 group.*

*2nd possibility:*

*One creates a group containing the meshes ranging between the rows nuini and nufin (included) in one existing group.*

*Example:*

```
CREA_GROUP_MA=_F (GROUP_MA = G1, NUME_INIT = 3  
, NUME_FIN = 7,  
NAME =  
GIP)
```

*Group GIP contains meshes 3, 4, 5,..., 7 of G1.*

**Caution:**

*These key words use the concept of order of the meshes in a group of meshes. This order is often unknown to the user. He can depend on the preprocessor. It is the order of the meshes at the time definition of the GROUP\_MA in the file of grid Aster.*

### *3.4.8 Operand*

*OPTION = "FACE\_NORMALE"*

*/OPTION = "FACE\_NORMALE"*

*This option makes it possible to define a GROUP\_MA made up of surface meshes of which the normal is parallel to the direction of the vector defined by its components if the key word is used VECT\_NORMALE or with that of the first vector of the new base defined by the change of reference mark due to the nautical angles.*

*In 3D, one supposes that the surface meshes are plane facets. They are of type TRIA3, TRIA6, QUAD4, QUAD8 or QUAD9. If one calls X1, X2, and X3 the vectors position of the first three nodes tops of the element, the normal is determined by the product vectorial:  $(X2 \ X1) \ (X3 \ X1)$ .*

*In 2D, one supposes that the surface meshes are right segments. They are of type SEG2 or SEG3. If one calls X1 and X2 the vectors position of the two nodes ends of the element, the normal is defined by  $(X2 \ X1) \ Z$  where Z is the perpendicular unit vector*

*in the plan and where one has affected 0. like third component with X2 X1.*

**Note:**

*A mesh “facet” will be retained if its normal is colinéaire with the normal vector defined by VECT\_NORMALE [§ 3.3.6.2]. This condition must be checked except for a certain precision (key word ANGL\_PREC [§ 3.3.6.3]).*

*When one chooses a ANGL\_PREC (for example 30. degrees), one defines in fact the group of meshes whose normal belongs to the cone of axis VECT\_NORMALE and point angle ANGL\_PREC.*

*This can be used (for example) to gather the meshes of a half wraps spherical (ANGL\_PREC = 90.).*

### **3.4.8.1 Operand**

**ANGL\_NAUT**

**/ANGL\_NAUT**

**=**

**in 2D**

**(,) in 3D**

*The nautical angles, defined in degrees, are the angles making it possible to pass from the reference mark*

*total of definition of the co-ordinates of the nodes to a reference mark whose first vector indicates the direction according to which the normal of the surface meshes is directed which one wishes to recover.*

*For the definition of the nautical angles, to see operator AFFE\_CARA\_ELEM [U4.42.01] operand ORIENTATION.*

***GROUP\_NO\_ORIG***

***=***

***gnoA***

***,***

***/***

***GROUP\_NO\_EXTR***

***= gnoB,***

***One defines nodes A and B, origin and end of segment AB.***

***PRECISION***

**= prec,**  
**CRITERION =/“RELATIVE”,**

**/“ABSOLUTE”,**

*These two arguments are parapets, they are used to check that the nodes that one seek to order (lno2 or gno2) are well on segment AB. If the variation of a node with AB is higher than prec the code stops in fatal error.*

*If the selected criterion is “RELATIVE”, the distance from a node with AB will be divided by the length AB.*

### **3.5.11 Operand OPTION = “NOEUD\_ORDO”**

*This option is used to create an ordered group\_no containing the nodes of a whole of meshes formed segments (SEG2, SEG3 or SEG4). The whole of these meshes must form a continuous line, opened having two ends.*

**GROUP\_MA**  
**= gmaAB**

*Name of the group\_ma which one wants to order the nodes.  
The meshes of gmaAB must form an open line.*

**/NOEUD\_ORIG =**  
**noA**  
**,/NOEUD\_EXTR =**  
**noB**

**,**  
**/**  
**GROUP\_NO\_ORIG**  
**=**  
**gnoA**

**,**  
**/**  
**GROUP\_NO\_EXTR**  
**= gnoB,**

*The key words make it possible to define nodes A and B, origin and end of line AB.*

*Node A will be numbered in first, then one is useful oneself of the topology of the meshes of gmaAB for*

*to number the nodes gradually.*

*If node A is not provided by the user, the program will choose like node “origin”, the first node of gmaAB which belongs only to only one mesh segment. The origin is thus arbitrary: program could just as easily have fallen on the other end.*

*It is checked that the last numbered node is well B (if this one is given).*

### **3.5.12 Operand OPTION = “TUNNEL”**

*This option is used to create the formed group\_no of the nodes located inside a “tunnel” which one provides the axis and the ray. The nodes selected will be those whose distance to the axis is lower than the ray.*

*The axis of the “tunnel” is defined by the linear meshes provided via key words MAILLE\_AXE and GROUP\_MA\_AXE.*

*The axis of the tunnel must have a “origin” defined by key words NOEUD\_ORIG and GROUP\_NO\_ORIG.*

*The key word RAY is used to define the “ray” of the tunnel.*

*Instruction manual*

*U4.2- booklet: Grid*

*HT-62/06/004/A*

---

**Code\_Aster** ®

**Version**

**8.2**

**Titrate:**

**Operator DEFI\_GROUP**

**Date:**

**31/01/06**

**Author (S):**

**J. Key PELLET**

**:**

**U4.22.01-H1 Page:**

**16/18**

*One can limit the tunnel by giving his length by the key word LENGTH. This length is measured starting from the origin of the tunnel.*

*The nodes candidates to belong to the tunnel are those carried by the meshes defined by the words keys: TOUT=' OUI', GROUP\_MA and MESH.*

### **3.5.13 Operands GROUP\_MA and NAME**

*/GROUP\_MA = lgma*

*For each group of meshes of the list lgma, one creates a group of nodes formed of nodes carried by the meshes of this group of meshes.*

*NAME = lgn*

*If lgn is provided by the user, this list must be of the same length than lgma. It are the names which one wants to give to the new groups of nodes.*

*If lgn is not provided, the groups of nodes will bear the same names as them groups of meshes which gave them birth.*

**CRIT\_NOEUD**

*=  
/“ALL” [DEFECT]  
: all the nodes of each mesh are taken.*

*/“SUMMIT”: one takes only the nodes “top” of the meshes (i.e. them ends of stop).*

*/“MEDIUM”: one does not take that the nodes “medium” of stop meshes.*

*/“CENTER”: one takes only the nodes which are neither “top” nor “medium” i.e. nodes in the center of the facets or the elements voluminal.*

### **3.5.14 Operand TOUT\_GROUP\_MA**

*/TOUT\_GROUP\_MA = “YES”*

*This key word with the same significance as the precedent, except that one creates groups of nodes for all the existing groups of meshes of the grid.*

### **3.5.15 Operand ALARMS = “YES” [DEFECT]/“NOT”**

*if ALARM = “NOT”, the code does not emit alarm; for example when one asks him to create one GROUP\_NO and that this group is empty. The default value of this key word is “YES”.*

### **3.5.16 Operand INFORMATION**

*if INFORMATION = 1, one prints in the file “MESSAGE”, the number of groups create and for each group, the name of the group and the number of entities the component.*

*if INFORMATION = 2, one prints in the file “MESSAGE”, the number of groups create and for each group, the name of the group, the number of entities the component then the list of the entities constituting it or groups.*

*Author (S):*

*J. Key PELLETT*

*:*

*U4.22.01-H1 Page:*

*17/18*

### **4 Examples**

*Example 1 (topological criteria and logics):*

*That is to say a my grid containing the groups of meshes already:*

*M1 m2 m3*

*and groups of nodes:*

***N1 N2 N3***

*my = DEFINI\_GROUP (reuse = my, GRID = my,*

*CREA\_GROUP\_MA = (\_F (NAME = NM1,  
NET = (MA7, MA9,...)*

*),  
\_F  
(  
NAME  
=  
NM2, UNION  
=  
(M1,  
NM1)  
)  
\_F  
(  
NAME  
=  
NM3, DIFFE  
=  
(NM2,  
M2)  
),),*

*CREA\_GROUP\_NO = \_F (TOUT\_GROUP\_MA = "YES"),*

*)*

*my = DEFINI\_GROUP (reuse = my, GRID = my,*

*CREA\_GROUP\_MA = \_F (NAME = NM4,  
NET = (MA7, MA11, MA13))*

$CREA\_GROUP\_NO = (_F (NAME = NN1,$   
 $INTERSEC = (NM1, N1)),$   
 $_F ($   
 $GROUP\_MA = NM4)))$

After these two calls to order *DEFI\_GROUP*, the grid contains then:

.

groups of meshes:

-  
 $M1, m2, m3$  (initial)

-  
 $NM1 =$  (meshs:  $MA7, MA9, \dots$ )

-  
 $NM2 = M1$  “union”  $NM1$

-  
 $Nm3 = NM2$  “minus”  $m2$

-  
 $NM4 =$  (MESHs:  $MA7, MA11, MA13$ )

.

groups of nodes:

-  
 $N1, N2, N3$  (initial)

-  
 $M1, m2, m3, NM1, NM2, Nm3$ : group\_no containing the nodes of the group\_ma of **same names**. These group\_no is created by 1st order *DEFI\_GROUP*.

-  
 $NN1 = NM1$  “intersection”  $N1$

-  
 $NM4 =$  (nodes of group\_ma  $NM4$ )

### **Example 2 (geometrical criteria):**

$my = DEFI\_GROUP$  (reuse =  $my$ ,  $GRID = my$ ,  
 $CREA\_GROUP\_MA =$   
 $(_F$   
 $(NAME = facesup, OPTION = “FACE\_NORMALE”,$

$VECT\_NORMALE$

=  
 $(0,$

0.,

1.)),

### *3 General information*

*In the documentation of this order, one will speak about:*

- .*
- macronutrient: object of the macr\_elem\_stat type [U4.62.01],*
- .*
- super-mesh: geometrical entity supporting one macro\_élément,*
- .*
- initial grid when one indicates the grid which was used to generate a macronutrient,*

.  
**final** grid to indicate the grid produced by this order.

By extension these adjectives **initial/final** will apply to the entities attached to the grids: node, net, group of nodes.

Practically, to build the final grid:

.  
one defines super-meshes while positioning in the space (2D or 3D) of the macronutrients existing (same a `macr_elem_stat` can generate several super-meshes),

.  
one resticks the super-meshes between them,

.  
one re-elects, if it is wanted, certain nodes,

.  
one creates, if it is wanted, certain groups of nodes.

**Note:**

One can note that the grid created by this order is made only of super-meshes.

One thus cannot (for example), to draw it with the usual post-processors.

possibilities of curing it will be able to exist with order `DEFI_SQUELETTE` [U4.24.01].

To mix finite elements “traditional” and substructures, it is necessary to use the operator of “concatenation” of grids [U4.23.03]: `mag = ASSE_MAILLAGE ( MAILLAGE= (m1, m2))`

A grid resulting from operator `DEFI_MAILLAGE` contains:

.  
super-meshes,

.  
nodes,

.  
groups of nodes.

The super-meshes are defined by translation/rotation of macronutrients.

As a “traditional” mesh, a super-mesh is entirely defined by the list of its nodes.

coordinated nodes of the meshes are those of the external nodes of the macronutrients transforms by the geometrical transformation: translation, rotation...

If one does not carry out a sticking together (cf `RECO_GLOBAL/RECO_MAILLE`), the grid has as much of

*nodes that the sum of the nodes of the super-meshs.*

### ***CI convention:***

*When one “resticks” the super-meshs, one eliminates certain nodes. By convention, at the time of one elimination of coinciding nodes, one preserves the node (and thus its co-ordinates) which comes from first mesh of the list l\_mail (cf RECO\_GLOBAL/RECO\_MAILLE).*

*As in any grid Aster, the nodes **are named**. By defect, the names of the nodes are given by the program in the form: NOijklmn where ijklmn is a number ranging between 000001 and 999999.*

*Key words DEFI\_NOEUD and DEFI\_GROUP\_NO make it possible the user to re-elect certain nodes and to define groups of nodes.*

## ***4 Operands***

### ***4.1 Word***

***key***

***DEFI\_MAILLE***

***DEFI\_MAILLE =***

***This key word factor makes it possible to define the super-meshs of the grid using macr\_elem\_stat.***

#### **4.1.1 Operand**

**MACR\_ELEM\_STAT**

**MACR\_ELEM\_STAT = l\_se**

*l\_se is the list of the names of the macronutrients which will generate the meshes.*

#### **4.1.2 Operand**

**NET**

**NET = l\_mail**

*l\_mail is the list of the names which one wants to give to the meshes. This argument is optional. In sound*

*absence, one will give to the meshes the names macronutrients (this is obviously impossible if one wants to use several times the same macronutrient).*

#### **4.1.3 Geometrical operands of transformations**

**/TRAN**

=

*This key word defines the translation to be applied to the macr\_elem\_stat:*

.

*if one is in 2D, one awaits 2 realities: (tx, ty),*

.

*if one is in 3D, one awaits 3 realities: (tx, ty, tz).*

**/ANGL\_NAUT**

=

**CENTER =**

*These key words define rotation to be applied to the macr\_elem\_stat.*

*If one is in 2D, one awaits 3 realities:*

.

*is the angle (in degrees) of rotation in the plan for ANGL\_NAUT,*

.

*px and py are the co-ordinates of the centre of rotation for CENTER.*

***If one is in 3D, one awaits 6 realities:***

.  
***, and are the nautical angles of rotation (in degrees). (Cf the operator  
AFFE\_CARA\_ELEM [U4.42.01]) for ANGL\_NAUT,***  
.

*px, py and pz are the co-ordinates of the centre of rotation for CENTER.*

***Important remark:***

*It is known that the key word order is not significant for Aster. The operation of  
translation/rotation is conventionally made in the order rotation **then**  
translation. These two operations do not commute in general.*

*Instruction manual*

*U4.2- booklet: Grid*

***J. Key PELLET***

*:*

*U4.23.01-G Page*

*: 5/10*

***4.2 Word***

***key***

***RECO\_GLOBAL***

*/ RECO\_GLOBAL*

*=*

*/ALL = "YES",*

/MESH = l\_maille,

/ CRITERION =/"ABSOLUTE",

/  
"RELATIVE"

,  
[DEFECT]

/  
PRECISION

=  
/prec,

/  
1.D-3,  
[DEFECT]

*This key word makes it possible to restick a whole of super-meshs **automatically** (indicated by the key word NETS or the key word ALL) with a criterion of proximity geometrical: 2 nodes of 2 different super-meshs m1 and m2 will be confused if outdistance which separates them is:*

<  
prec

(CRITERION  
=  
"ABSOLUTE"),

<  
prec\*min (D (m1), D (m2))  
(CRITERION  
=

“RELATIVE”).

where  $D$  (semi) note the smallest distance between 2 nodes of the semi super-mesh.

**Note:**

Two nodes of the same mesh will never be restuck.

If a mesh contains one node, the CRITERION should be used = “ABSOLUTE”.

### 4.3 Word

key

**RECO\_MAILLE**

RECO\_MAILLE

=

This key word factor makes it possible to restick “**with the hand**” certain super-meshes indicated by the user. The super-meshes which one can restick are those which were defined by the key word **DEFI\_MAILLE**. On then resticks the super-meshes via groups of nodes. To say what one wants to restick it is thus necessary to give couples (mesh, group of nodes (of the initial grid)).

**Note:**

When one gives a couple (mesh, group of nodes), one indicates the list of the nodes of group nodes which are external for the **macr\_elem\_stat** which defines the super-mesh. It is in fact the intersection of the group of nodes and the edge of the substructure. This list is ordinate as the initial group of nodes.

In theory, when one resticks 2 meshes via 2 groups of nodes, the whole of the nodes indicated must restick itself (cf the convention chosen by the key word **OPTION**). A message of alarm will be emitted if it is not the case.

#### 4.3.1 Operands

**NET/GROUP\_NO**

NET

=

One gives the list of the meshes here to be restuck. In general, one resticks meshes 2 by 2.

For the “corners”, it can be pleasant to restick all the convergent meshes in only once (for example the 4 super-cubic ones which divides the same edge).

GROUP\_NO

=

*One gives here the list of the groups of nodes to be restuck. This list is of the same length than list meshes.*

*U4.23.01-G Page*

*: 6/10*

### **4.3.2 Operand**

#### **OPTION**

*OPTION*

*=*

*This word makes it possible to choose the convention of sticking together of the lists of nodes defined by groups of nodes.*

*.*

**“GEOMETRICAL”:**

*The program will confuse the nodes by considerations of geometrical proximity.*

*(Cf key word: RECO\_GLOBAL)*

*.*

**“OPPOSITE” “NOEUD\_A\_NOEUD”/:**

*That is to say:  $G1 = \{A1, B1,\}$*

*C1*

*$G2 = \{A2, B2,$*

```
}  
C2  
G3 = {A3, B3,  
}  
C3
```

If *OPTION* = “*NOEUD\_A\_NOEUD*”, *GROUP\_NO* = (*G1*, *G2*, *G3*)

*one will restick:*

*A1 with*  
*A2 with*  
*A3*  
*B1 with*  
*B2 with*  
*B3*  
*C1 with C2 with C3*

If *OPTION* = “*OPPOSITE*”

,  
*GROUP\_NO* = (*G1*, *G2*, *G3*)

*one will restick: C1 with A2 with A3*

*B1 with*  
*B2 with*  
*B3*  
*A1 with C2 with C3*

***Caution:***

*For “OPPOSITE” option, only the first group of nodes of the list of the GROUP\_NO is “turned over”.*

***4.4 Word***

***key***  
***DEFI\_NOEUD***

***DEFI\_NOEUD***

***=***

*This key word factor makes it possible to re-elect whole or part of the nodes of the grid.*

## **4.4.1 Operands**

### **ALL/PREFIX/INDEX**

/  
*ALL* = "YES",

= *pref* *PREFIXES*,

*INDEX* = (*DM*, *Fm*, *dn*, *fn*),

*These key words make it possible to re-elect all the nodes of the grid. The convention of renaming is as follows (in pseudo FORTRAN):*

*no\_fin* (*K8*) = *pref//no\_mail* (*DM: Fm*) *//no\_ini* (*dn: fn*)

*Instruction manual*

*U4.2- booklet: Grid*

*HT-66/05/004/A*

---

*Operator* *DEFI\_MAILLAGE*

*Date:*

31/01/05

*Author (S):*

**J. Key PELLET**

:

*U4.23.01-G Page*

: 7/10

*What wants to say that the name of a node will be formed while concaténant:*

.

*the prefix possibly given by the user,*

.

*under-chains of characters extracted the name of the mesh which carries this node (cf CI convention of elimination of the nodes stated above [§ 3]). One takes the characters of row ranging between DM and Fm. If DM > Fm, this*

*under-chains is empty,*

.

*under-chains of characters extracted the name of the node (in its grid initial). One takes the characters of row ranging between  $dn$  and  $fn$ . If  $dn > fn$ , this under-chain is empty.*

*It is necessary thus that:  $ltot = \text{length}(\text{prefix}) + (Fm-dm+1) + (fn-dn+1) 8$*

*It is pointed out that 2 nodes cannot have the same name in the same grid. The goal “play” for the user is to manage to re-elect certain nodes (without too many efforts of its share) in a conventional way without this convention leading to names identical.*

*A frequent case is as follows:*

*if the grids which gave rise to the macronutrients come from one preprocessor which generates names of nodes of the  $NOijklmn$  form and if the user gives to his super-meshs names with 2 characters: SA, SB,.... the sequence:*

*DEFI\_NOEUD = \_F (TOUT= “YES”, INDEX= (1, 2, 3, 8,))*

*will generate nodes of names: SA000001, SA000002,... , SB000001,*

#### **4.4.2 Operands**

**NOEUD\_FIN/MESH/NOEUD\_INIT**

/

**NOEUD\_FIN**

= *no\_fin*,

**NET**

=

*email*,

**NOEUD\_INIT**

=

*no\_ini*,

*These key words make it possible to re-elect nodes **one by one**:*

.

*no\_fin is the name which one wants to give to the node grid that one creates*

*(final).*

*email and no\_ini identify the node to be re-elected: email is the name of super-mesh which carries the node, no\_ini is the name of the node in the grid who was used to create the macr\_elem\_stat which defined the super-mesh email.*

#### **4.5 Word**

**key**

**DEFI\_GROUP\_NO**

*DEFI\_GROUP\_NO*

=

*This paragraph is almost identical to precedent (DEFI\_NOEUD) by replacing word NOEUD\_ by word GROUP\_NO.*

*This key word factor makes it possible to define groups of nodes starting from groups existing in initial grids of the macronutrients.*

#### **Note:**

*An initial group of nodes can contain nodes which do not belong to the edges of macronutrients. These internal nodes thus do not exist in the final grid. By convenience, one takes convention nevertheless to create the group reduced to its intersection with the edge of the macronutrient.*

### 4.5.1 Operands

#### *ALL/MESH/PREFIX/INDEX*

/  
/ALL = "YES",

/MESH = email,

= pref PREFIXES,

INDEX = (DM, Fm, dn, fn),

*These key words make it possible to create all the groups of nodes corresponding to groups of the initial grid associated the mesh email or all the meshes if:*

TOUT= "YES".

*The convention of renaming is as follows (in pseudo FORTRAN):*

*gno\_fin (k8) = pref//no\_mail (DM: Fm) //gno\_ini (dn: fn)*

*What wants to say that the name of a group of nodes will be formed while concaténant:*

.  
*the prefix possibly given by the user,*

.  
*under-chains of characters extracted the name of the mesh,*

.  
*under-chains of characters extracted the name of the group\_no of the initial grid.*

*It is necessary thus that:*

*ltot= length (prefix) + (Fm-dm+1) + (fn-dn+1) 8*

*A frequent case is as follows*

*: the grids which gave rise to*

*macronutrients come from a preprocessor which generates names of the form*

*GRNOijkl. If the user gives to his super-meshes names with 2 characters: SA,*

*SB,...., the sequence:*

*DEFI\_GROUP\_NO=\_F (TOUT= "YES", PREFIXE=' GN', INDEX= (1,2,5,8))*

*Will generate groups of nodes of names:*

*GNSA0001, GNSA0002,... , GNSB0001.*

#### **4.5.2 Operands**

**GROUP\_NO\_FIN/MESH/GROUP\_NO\_INIT**

/  
*GROUP\_NO\_FIN = gno\_fin,*

*NET = email,*

*GROUP\_NO\_INIT  
= gno\_ini,*

*These key words make it possible to create groups of nodes **one by one**:*

- 
- gno\_fin is the name which one wants to give to the GROUP\_NO,*
- 
- email and gno\_ini identify the initial GROUP\_NO:*
- 
- email is the name of the super-mesh which carries the GROUP\_NO,*
- 
- gno\_ini is the name of the GROUP\_NO of the initial grid.*

***U4.2- booklet: Grid***

***Document: U4.23.02***

***Operator CREA\_MAILLAGE***

## ***1 Goal***

***To create a structure of data of the grid type starting from an other grid. New grid contains all information of the old grid (if they still exist): nodes, meshes, groups of nodes and groups of meshes. The new grid is created starting from a grid existing while duplicating, while destroying, while transforming or while bursting,..., of the meshes.***

***Product a structure of data grid.***

***3 Operands***

***3.1 Operand***

***GRID***

***GRID = ma\_1***

***ma\_1 is the name of the initial grid which one wants to reproduce before “enriching it” by new meshes or nodes, or “to impoverish it”.***

***Note:***

***The key word GRID is obligatory except for the use of key word ECLA\_PG.***

***3.2 Word***

***key***

***CREA\_GROUP\_MA***

***/ CREA\_GROUP\_MA***

***An occurrence of this key word factor makes it possible to define a new group of meshes made up new meshes, being based themselves on existing nodes.***

***To duplicate several groups of meshes, one will repeat the key word factor CREA\_GROUP\_MA.***

***Contrary to the order DEFI\_GROUP [U4.22.01] for which the concept grid always preserve the same number of meshes and nodes, here the number of meshes of new grid is increased (the number of nodes remains identical because the new meshes rest on already existing nodes).***

***This can facilitate the creation of new loci to be able to apply modelings different on the same group from meshes.***

### **3.2.1 Operand**

**NAME**

**NAME = noma**

*One gives here the name (without “quotes”) of the new group of meshes which will be created.*

### **3.2.2 Operands**

**NET/GROUP\_MA/ALL**

**/NET**

**=**

**lmail,**

**/GROUP\_MA**

**=**

**lgma,**

**/ALL =**

**“YES”,**

*The whole of the meshes stipulated by the user with these three key words will be duplicated and them new meshes will be gathered in a group of meshes bearing the name stipulated by the word key NAME. If the whole of the meshes to be duplicated contains meshes in double, they are eliminated.*

### **3.2.3 Operands**

**PREF\_MAILLE/PREF\_NUME**

**PREF\_MAILLE = pre\_ma**

*This variable text makes it possible to define the name of the new meshes. One obtains the name of new mesh while adding in front of its old name, the text specified under the key word PREF\_MAILLE. If this new name has a length higher than eight characters, one stop in fatal error with an error message.*

**Instruction manual**

**U4.2- booklet: Grid HT-62/06/004/A**

**Code\_Aster ®**

**Version**

**8.2**

**Titrate:**

**Operator CREA\_MAILLAGE**

**Date:**

**31/01/06**

**Author (S):**

**J. PELLE, L. VIVAN Key**

**:**

**U4.23.02-F1 Page:**

**6/14**

**PREF\_NUME**

**=/ind**

***If an entirety ind is given under key word PREF\_NUME, the number of the new meshes is built by concaténant the text capital letter given under key word PREF\_MAILLE and an entirety obtained by incrementing ind of 1 with each creation of new meshes.***

**Note:**

***The user must be careful in the choice of his prefix to prevent that the meshes news has the same name as old meshes. This collision of names is detected by the order and conduit with a program stop.***

**3.3 Word**

**key**

**CREA\_MAILLE**

**/ CREA\_MAILLE**

***An occurrence of this key word factor makes it possible to define new meshes while duplicating already existing meshes. For the use of the key words, one returns in the paragraph [§3.2]. Only difference, the meshes created are not gathered in a named group of meshes.***

**3.4 Word**

**key**

**CREA\_POII**

**/ CREA\_POII**

***An occurrence of this key word factor makes it possible to define meshes of the type “POII” (mesh in one only node) starting from nodes or groups of nodes, or nodes of meshes or group of meshes.***

**3.4.1 Operands**

**ALL/GROUP\_MA/MESH/GROUP\_NO/NODE**

**/ALL = “YES”,**  
**/GROUP\_MA**  
**= lgma,**  
**/NET**  
**= lmail,**  
**/GROUP\_NO**  
**= lno,**  
**/NODE**  
**= lnoeud,**

*All the nodes which belong to entities stipulated by the user with these five key words, generate a mesh of the type POII. The mesh created will have the same name as the node which support.*

### **3.4.2 Operand**

**NOM\_GROUP\_MA**

**NOM\_GROUP\_MA = nom\_ma**

*All meshes POII thus created can be gathered in the same group of meshes named nom\_ma.*

### **3.5 Word**

**key**

**DETR\_GROUP\_MA**

**/DETR\_GROUP\_MA**

*An occurrence of this key word factor makes it possible to destroy groups of meshes, the meshes contained in these groups are not they not destroyed.*

:

**U4.23.02-F1 Page:**

**7/14**

### **3.5.1 Operand**

**GROUP\_MA**

**/GROUP\_MA = lgma**

*The groups of meshes stipulated in the list lgma are destroyed.*

### **3.5.2 Operand**

**NB\_MAILLE**

**NB\_MAILLE =/nb\_mail,**

**/ 0,**

*All the groups of meshes having a number of meshes lower or equal to nb\_mail are destroyed.*

### **3.6 Word**

**key**

**MODI\_MAILLE**

**/**

**MODI\_MAILLE**

*An occurrence of this key word factor makes it possible to transform:*

- respectively the meshes segment with three nodes, triangle with six nodes and quadrangle with eight nodes in segment with four nodes, triangle with seven nodes and quadrangle with nine nodes. Additional nodes are consequently added in the grid. For the triangles and the quadrangles, each additional node is obtained like geometrical barycentre of the nodes tops of the mesh considered. For the segments, the nodes mediums are placed at the third and the two-third of the segment, curve of the element being respected.*
- the meshes quadrangles in meshes triangles with three nodes.*

### **3.6.1 Operand**

**ALL**

/  
**ALL = "YES"**

*One applies the transformation to all the meshes of the grid.*

### **3.6.2 Operand**

**NET**

/  
**NET = lmail**

*This key word makes it possible to define a list of meshes setting up the group of meshes which will be transforms.*

### **3.6.3 Operand**

**GROUP\_MA**

/  
**GROUP\_MA = lgma**

*The meshes of the groups of meshes given in the list lgma are transformed.*

### **3.6.4 Operand**

**OPTION**

**OPTION =/"SEG3\_4"  
"TRIA6\_7"  
"QUAD8\_9"  
"QUAD\_TRIA3"**

*This key word indicates the transformation to be carried out:*

- *transformation of the segments with three nodes into segments with four nodes (usable by example for modeling "PIPE" of AFFE\_MODELE [U4.41.01],*
  - *transformation of the triangles with six nodes into triangles with seven nodes,*
  - *transformation of the quadrangles with eight nodes into quadrangles with nine nodes,*
  - *transformation of the quadrangles into triangles with 3 nodes:*
- transformation of meshes of the type QUAD4 into two meshes of the type TRIA3*  
*transformation of meshes of the type QUAD8 into six meshes of the type TRIA3*  
*transformation of meshes of the type QUAD9 into six meshes of the type TRIA3*

**8/14**

### **3.6.5 Operands**

**PREF\_NOEUD/PREF\_MAILLE/PREF\_NUME**

**PREF\_NOEUD**

**=**

**/pre\_nd,**

**“NS”,**

***This variable text makes it possible to define the name of the new nodes. One obtains the name of new node while adding in front of its old name, the text specified under key word PREF\_NOEUD. In case where this new name has a length higher than eight characters, one stops in fatal error with an error message.***

**PREF\_MAILLE = pre\_ma**

***This variable text makes it possible to define the name of the new meshes. One obtains the name of new mesh while adding in front of its old name, the text specified under the key word PREF\_MAILLE. If this new name has a length higher than eight characters, one stop in fatal error with an error message.***

**PREF\_NUME =/ind,**

*/ 1,*

*If an entirety ind is given under key word **PREF\_NUME**, the number of the new nodes (new meshes) is built by concaténant the text capital letter given under the key word **PREF\_NOEUD** (**PREF\_MAILLE**) and an entirety obtained by incrementing ind of 1 with each creation new nodes (news meshes).*

*Note:*

*The user must be careful in the choice of his prefix to prevent that the new ones nodes (news meshes) have the same name as old nodes (news meshes). This collision of names is detected by the order and conduit with a program stop.*

*An automatic procedure of cutting of the meshes quadrangles in triangles can generate a kind of “polarization” of the grid: from a given grid **QUAD**, all them diagonals are found directed in the same direction.*

### **3.6.6 Checking**

*The meshes modified by the transformation must be of the same type as that stipulated under the key word **OPTION**.*

### **3.7 Word**

*key*

**LOCATE**

*/ LOCATE*

*An occurrence of this key word factor makes it possible to define a new grid from the old one grid by carrying out a change of reference mark.*

*This functionality is used in particular in macro-order **MACR\_CARA\_POUTRE** [U4.42.02] for the calculation of the constant of warping.*

#### **3.7.1 Operands**

**COUNT/NOM\_ORIG/NOM\_ROTA/GROUP\_MA**

**COUNT =**

*One gives here the name of the table of concept “geometrical characteristics” which contains in private individual, co-ordinates of the centre of inertia and the center of torsion, angles nautical defining the principal reference mark of inertia,... This table can be obtained by the order*

***POST\_ELEM with the key words factors CARA\_GEOM or CARA\_POUTRE [U4.81.22].***

***NOM\_ORIG***

***=/"CDG",***

***"TORSION",***

***GROUP\_MA***

***=***

***gma***

***If NOM\_ORIG = "CDG", one can indicate the name of the group of meshes whose centre of gravity will be the origin of the new reference mark. If one does not use GROUP\_MA, the centre of gravity of the unit***

*MODEL will be the origin of the new reference mark.*

*If NOM\_ORIG = "TORSION", key word GROUP\_MA is inoperative.*

### **3.8 Key word**

**LINE\_QUAD**

**/LINE\_QUAD**

*This functionality makes it possible to create a quadratic grid starting from a linear grid, one can to apply it only to part of the grid (attention in this case with the connection of the linear zones and quadratic).*

*The groups of meshes are preserved, the groups of nodes also, as at the time of refinement of grid the nodes created are not introduced into the groups of nodes.*

#### **3.8.1 Operands**

**NET/GROUP\_MA/ALL**

**/NET**

**=**

**lmail,**

**/GROUP\_MA**

**=**

**lgma,**

**/ALL =**

**"YES",**

*The whole of the meshes stipulated by the user with these three key words will be transformed into quadratic meshes.*

#### **3.8.2 Operands**

**PRE\_NOEUD/PREF\_NUME**

*As for MODI\_MAILLE.*

### **3.9 Key word**

**QUAD\_LINE**

**/QUAD\_LINE**

*This functionality makes it possible to create a linear grid starting from a quadratic grid, one can to apply it only to part of the grid (attention in this case with the connection of the linear zones and quadratic).*

*The groups of meshes are preserved, the groups of nodes also, as at the time of refinement of grid the nodes created are not introduced into the groups of nodes.*

### **3.9.1 Operands**

**NET/GROUP\_MA/ALL**

**/NET**

**=**

**lmail,**

**/GROUP\_MA**

**=**

**lgma,**

**/ALL =**

**“YES”,**

*The whole of the meshes stipulated by the user with these three key words will be transformed into linear meshes.*

### **3.10 Key word**

**COQU\_VOLU**

**/COQU\_VOLU**

*From the data of a group of surface meshes (QUAD, TRIA3), one builds the grid voluminal (HEXA8, PENTA6) by extrusion according to the normal of the elements (in a node, one takes the average of the normals of the convergent elements). Only one layer of elements is create.*

*The operation applies only to linear grids; if one wishes to create a grid quadratic, it is enough to use CREA\_MAILLAGE/LINE\_QUAD then.*

*The meshes created will bear a name formed starting from the prefix pre\_ma followed by a number. For example, if PREF\_MAILE=' FS' and PREF\_NUME=7, the meshes create will be called: FS7, FS8,...*

*One will create also a new GROUP\_MA (called nogma) containing the whole of meshes QUAD4 created.*

### **3.12.1 Operand NAME**

*Name of the group of meshes made up of the voluminal meshes created at the time of this operation.*

### **3.12.2 Operands GROUP\_NO\_1/GROUP\_NO\_2**

*Groups of node constituting the lips of the crack. The group of node GROUP\_NO\_1 carries them local nodes 1 and 2 (the first node of the group to a local classification equalizes to 1), it GROUP\_NO\_2 carries the local nodes 3 and 4 (the first node of the group to a local classification equalize to 4). Attention it is necessary to choose these groups of nodes according to the geometry of such kind that the local classification of the elements is carried out in the trigonometrical direction:*

GROUP\_MA*

*=*

*“hull”,  
PREF\_MAILLE*

*=*

*“A”,  
PREF\_NUME*

*=*

*100,  
)*

)

*After call to order CREA\_MAILLAGE, the new grid contains then:*

.

*groups of meshes:*

-

*hull (initial)*

-

*ground = (meshs: A100 A101)*

.

*the meshes are based on the following nodes:*

-

*M1: N1 N2 N3*

-

*M2: N3 N4 N5*

-

*M3: N4 N5 N6*

-

*NEWM3: N4 N5 N6*

-

*A100: N1 N2 N3*

-

*A101: N3 N4 N5*

: 3/4***

***3 Operands  
MAILLAGE\_1 and MAILLAGE\_2***

***MAILLAGE\_1 = ma1, MAILLAGE\_2 = ma2,***

***ma1 and ma2 are the names of the 2 grids to be assembled.***

***4 Operation  
=  
“SUPERIMPOSES”***

***With this choice: “SUPERIMPOSES”, all the entities (meshs, nodes, group\_ma and group\_no) of 2 grids are preserved. The only problem to be regulated relates to the name as of the these entities (conflict of names possible because the 2 grids can contain, for example, of the of the same nodes name).***

***To solve these possible problems of names:  
• The nodes and the meshs are always famous. That wants to say that the user cannot***

*to know the name of the nodes and meshes of the grid result. It will have in general to use (it who is always advised) the names of group\_no and group\_ma. Or it will have to print it grid to know the selected names.*

*· The names of the group\_no and group\_ma are preserved within the limit of the possible one. If 2 group\_ma (or 2 group\_no) has the same name in the 2 grids, the group coming from 2nd grid is famous automatically and the renaming is indicated in the file of message.*

## **5 Operation**

### **= “JOINING”**

*The operation “JOINING” is used to connect 2 grids which would have been with a grid independently in 2 distinct files (for example by 2 different teams).*

*If the 2 grids are not coherent on their interface (different discretization), the user will not have not other choice to use functionality AFFE\_CHAR\_XXX/LIAISON\_MAILLE “to bind” them degrees of freedom of the 2 grids which will remain topologically disjointed. It will have to then use the operation “SUPERIMPOSES”.*

*If on the other hand, the 2 grids were envisaged to be restuck, it will use the operation “JOINING”. For that, it will have to take the precaution to name the 2 groups of meshes (of interface) which will allow to restick the 2 grids. Moreover these 2 groups of meshes must be geometrically coincidents. The user will write then:*

*OPERATION=' COLLAGE', COLLAGE=\_F (GROUP\_MA\_1=' gma1', GROUP\_MA\_2=' gma2'),*

*The group\_ma gma1 and gma2 will then be amalgamated. More precisely:*

- the meshes of gma1 and gma2 will be removed*
- the nodes of gma2 will subisteront (but will be orphan)*
- the nodes of gma1 will connect the 2 grids.*

*Before “amalgamating” the 2 group\_ma gma1 and gma2, the program will check that the nodes of these*

*2 group\_ma are well coincidents (with a tolerance of 0.001 times the length of the smallest edge of the 2 grids).*

*The conflicts of names of the entities of the 2 grids are regulated in the same way that for the operation*

*“SUPERIMPOSES” (see above).*

**C. DURAND, J. Key PELLET**

**:**

**U4.23.03-G Page**

**: 4/4**

**6 Operation**

**=**

**“SOUS\_STR”**

*To mix in the same model of the ordinary finite elements and macronutrients (or under structures), it is necessary to have a grid containing at the same time ordinary meshes and (super) meshes. Operator ASSE\_CHAMP/OPERATION = “SOUS\_STR” makes it possible to constitute it*

*“mixed” grid by assembling a grid ordinary (or mixed) and a grid containing of (super) meshes (coming from DEFI\_MAILLAGE).*

*The direction of the assembly is as follows:*

**.**

*All entities of the 2 grids arguments ma1 and ma2 (meshs, super-meshs, nodes, group meshes and groups nodes) are recopied in the grid result: mac.*

**.**

*The only shared entities are the nodes same names. These are the nodes which allow to assemble the 2 grids.*

**.**

*Treatment of the entities bearing the same name:*

**-**

*nodes: nodes of the second grid bearing an existing name in the first grid, are not added: it is supposed that they are the same ones. Co-ordinates of preserved node are those of the node of the first grid. An alarm is emitted when the distance between the two confused nodes is higher than:*

**10 6**  
**- .d\_refe**

*where d\_refe is a length characteristic of the grid:*

**d\_refe**  
**=**  
**(D**  
**max (O**  
**, NR)**

*where D (O*  
*, NR*  
*) is the distance from the node NR at the origin of the total reference mark.*

-  
*meshs (or super-meshs): if the grid ma2 contains of the same meshs name than meshs of the first grid ma1, the program stops in fatal error.*

-  
*group meshs (or groups of nodes): if the grid ma2 contains a group of of the same meshs name than a group of mesh of ma1, this one is ignored and it program transmits a message of alarm.*

## **7 Examples**

### **7.1 ex2**

*One wants to create a grid (matot) containing static substructures and an ordinary grid.*

**ma1**

**= LIRE\_MAILLAGE ()**

**macro1 =**

**MACR\_ELEM\_STAT (...)**

**macro2 =**

**MACR\_ELEM\_STAT (...)**

## ***1 Goal***

***To carry out modifications on an existing grid. The possibilities of modifications are:***

- .  
to reorientate meshes of edge being used to apply a pressure,***
- .  
to reorientate meshes HEXA8 of modeling SHB8,***
- .  
to check the orientation of the normals on the elements of hull,***
- .  
to reorientate the meshes of full-course of elements of joint,***
- .  
to reactualize the grid starting from a deformation calculated previously,***
- .  
to transform a grid of plate into grid of tube, then possibly of elbow,  
(macro order MACR\_ASCOUF\_MAIL),***
- .  
to transform a grid of square into grid of pricking (MACR\_ASPIC\_MAIL),***
- .  
in a grid with bottom of crack, to move the nodes mediums of the edges touching it  
melts of crack to the quarter of these edges,***
- .  
to relocate a grid,***
- .  
to impose one or more rotations of unspecified axes on a grid,***
- .  
to generate a symmetrical grid compared to a plan in 3D or a line in 2D.***

***Product a structure of data of the grid type or modifies the structure of data (operator réentrant).***

### *3 Operands*

#### *3.1 Operand*

##### *GRID*

*GRID = my,*

*Grid of the type [grid] on which will amend and/or checks.*

#### *3.2 Operand*

##### *MODEL*

*MODEL = Mo,*

*Concept produced by AFFE\_MODELE [U4.41.09] where the types of affected finite elements are defined on the grid. This operand is obligatory for key words.*

#### *3.3 Operand*

##### *INFORMATION*

*INFORMATION*

*=*

*Indicate the level of impression of the results of the operator,*

*1 = no impression,*

*2 = impression of the meshes whose connectivity was modified, including the impression of old and new connectivities.*

*The impressions are made in the file "MESSAGE".*

### **3.4 Key word** **ORIE\_FISSURE**

#### **ORIE\_FISSURE**

=

*This key word is used to reorientate (if necessary) the meshes of a group forming “full-course” elements. It functions in 2D and 3D [Figure 3.4-a].*

*Appear 3.4-a*

*Currently, this key word is useful only in 2D to reorientate the elements of joint (modelings **AXIS\_FISSURE** and **PLAN\_FISSURE**).*

*The user specifies (with key word **GROUP\_MA**) which are the meshes candidates with reorientation (the “full-course one”).*

*These meshes must be “prisms” (**QUAD** in 2D, **HEXA** and **PENTA** in 3D).*

*The “transverse” direction with the layer is given in a topological way (and not according to a criterion*

*of flatness): the facets connecting the elements of the layer are declared “transverse”. This algorithm imposes that the layer is made of several contiguous meshes.*

*Note:*

*The “reorientation” about which one speaks here actually consists in modifying the definition of connectivity*

*meshes. For example, in 2D, convention is that sides 2 and 4 of the quadrangles are transverses with the layer.*

#### ***TRANSLATION***

##### ***Caution***

***One can combine this functionality with ROTATION, but these operations are not commutative.***

***One cannot combine this functionality with SYMMETRY.***

***TRANSLATION = (n1, N2, [n3]),***

***[l\_R]***

***Single-ended spanner word for the translation of a grid following a vector.***

### ***3.14 Key word***

#### ***ROTATION***

##### ***Caution***

***One can combine this functionality with TRANSLATION, but these operations are not***

*commutative. On the other hand, it is not authorized to use ROTATION, MODI\_BASE and SYMMETRY at the same time.*

**ROTATION =**

*Key word factor for the unspecified rotation of axis of a grid.*

**POIN\_1**  
= (nor, N2, [n3]),  
[l\_R]

*Co-ordinates of the first point to define the axis of rotation.*

**/POIN\_2**  
= (nor,  
N2,  
[n3]),  
[l\_R]  
/  
**DIR**

= (nor, N2, [n3]),  
[l\_R]

*Co-ordinates of the second point or direction to define the axis of rotation completely.*

**ENG = has,**  
[R]

*Swing angle expressed in degrees.*

*Rotation is done in the direct direction, compared to its directed axis. This axis passes by the point POIN\_1 and its orientation are given, either by vector DIR, or by the vector of origin POIN\_1 and of end POIN\_2.*

*Rotation is defined by:*

*Either M (X, y, Z) a point of space, one imposes a rotation of angle to him (in radians) of which the axis passes by P (px, py, pz) and has as a direction D (dx, Dy, dz). Then M becomes Me after rotation:*

$$M = P + \cos PM + (1 - \cos) (PM D) D + \sin (D PM)$$

### **3.15 Key word**

**SCALE**

#### **Caution**

*This functionality is usable with TRANSLATION and ROTATION with which it commutates. One cannot combine this functionality with SYMMETRY.*

*SCALE = n1,*  
*[R]*

*Single-ended spanner word for the scaling of a grid following a reality.*

*Either  $M(X, y, Z)$  a point of the grid, it will become, by this transformation of report/ratio  $n1$ :  $Me(n1.x, n1.y, n1.z)$ .*

### **3.16 Key word**

**MODI\_BASE**

#### **Caution**

*This functionality is not authorized with ROTATION and SYMMETRY.*

*MODI\_BASE =*

*Key word factor for the basic change in which one expresses the co-ordinates of one grid.*

$VECT\_X = (n1, N2, [n3]),$   
 $[l\_R]$

*Coordinated first vector of the new base, unspecified standard.*

$VECT\_Y = (n1, N2, [n3]),$   
 $[l\_R]$

*Coordinated second vector of the new base (not used in 2D), also of standard unspecified.*

*In 2D, it is enough to give axis  $VECT\_X$ , and Code\_Aster builds the second automatically vector to define a direct orthogonal base. A test checks if  $VECT\_X$  is of standard not null.*

*In 3D, one checks that  $VECT\_X$  and  $VECT\_Y$  are of nonnull standard and one checks that they are orthogonal. The third vector which supplements the base is built as being the product vectorial of  $VECT\_X$  with  $VECT\_Y$ . One thus secures construction of an orthogonal base direct.*

*Then, in all the cases (2D and 3D), the vectors of the base are normalized to 1, the user does not have thus not to be concerned with it. There is thus finally a direct orthonormée base.*

*In 3D, one thus awaits the data of  $VECT\_X$  and  $VECT\_Y$ , the first two vectors of new base. Then the basic change is defined as:*

$VECT\_Z (X, y, Z) = VECT\_X (X, y, Z) VECT\_Y (X, y, Z)$

$B = (VECT\_X, VECT\_Y, VECT\_Z)$

***TRAITER\_BORD***

***=/“YES”***

***/“NOT”***

***Allows geometrically to carry out a particular treatment with the meshes of edges (to the direction include in another mesh) before partitioning: those are withdrawn from the grid with partitionner then reinjected after partitioning. This treatment allows stage some difficulties of the partitionnor, who can in certain cases separate a mesh from edge of his mesh father.***

### ***3.8 Operand***

***VERIF\_CONNEX***

***CORRECTION\_CONNEX =/“YES”***

***/“NOT”***

***A not-connexity of a under-field can generate difficulties convergence of seeing plantings of the algorithm of resolution of FETI.***

***Option CORRECTION\_CONNEX makes it possible to check the connexity of the under-fields. In the case***

***of one or more under-field not-related, under additional fields are generated from each not-related block. The under-fields thus obtained can to be unbalanced in terms of a number of elements.***

### ***3.9 Operand GROUPING***

***GROUPING***

***=  
\_F  
(***

***GROUP\_MA = grma,)***

***Allows partitionement to generate one in which meshes of the group of meshes “grma” will be obligatorily placed in the same under-field.***

### ***3.10 Operand EVALUATION***

***POIDS\_MAILLES***

=  
***\_F***  
(

***GROUP\_MA = grma,***  
***WEIGHT***  
***= I***  
***, )***,

***By defect, all the meshes have a weight of 1. This key word factor makes it possible to affect to meshes defined by a group of meshes a weight given by the user. This option allows to generate under-fields of which the number of meshes is not equivalent. One of interests is to be able to generate smaller under-fields where one predicts than calculation will be more difficult (zone of plasticization, etc...).***

***Document: U4.24.01***

***Operator*** **DEFI\_SQUELETTE**

***1 Goal***

***To define the grid of visualization of the results of a dynamic under-structuring.***

*In the case of the cyclic dynamic under-structuring, the grid is created by using whole or part meshes (grid of visualization) of the structure sector then by repeating it in a cyclic way to reconstitute the total structure.*

*In the case of the general dynamic under-structuring, the grid is created by using all or part of the meshes (grid of visualization) of the various substructures then by associating them of manner to reconstitute the total structure.*

*The meshes used (called meshes of visualization) are not necessarily support of one finite element. This makes it possible to use meshes of visualization in a reduced number, different from meshes of calculation, and representing coarsely the form of the structure (skeleton).*

*One can also create a skeleton starting from an other skeleton which one will amalgamate certain nodes interfaces according to a criterion of proximity.*

*Restriction: The meshes of visualization must be defined starting from nodes supporting of the degrees of freedom of calculation (there is no interpolation of the results).*

*This operator creates a structure of data of the skeleton type.*

## **3 Operands**

### **3.1 Under-structuring cyclic**

#### **3.1.1 Operand**

**MODE\_CYCL**

*MODE\_CYCL = mocy*

*Concept mode\_cycl resulting from a calculation in cyclic under-structuring.*

### **3.1.2 Word**

*key*

**SECTOR**

*SECTOR*

*Key word factor for the creation of a skeleton starting from a result of the mode\_cycl type produced by MODE\_ITER\_CYCL [U4.52.05]. Allows to define on the basic sector the list of the meshes of visualization which will be repeated in a cyclic way.*

#### **3.1.2.1 Operands**

**ALL/MESH/GROUP\_MA**

*/*

*ALL*

*All the meshes of the grid of the basic sector will be meshes of visualization.*

*/| MESH*

*=*

*filed*

*List meshes of visualization of the basic sector.*

*/*

*GROUP\_MA = grma*

*List groups of meshes of visualization of the basic sector.*

### **3.2 Under-structuring traditional**

#### **3.2.1 Operand**

**MODELE\_GENE**

*MODELE\_GENE = mogene*

*Name of the concept modele\_gene resulting from DEFI\_MODELE\_GENE [U4.65.02] defining the structure*

*total on which one wishes to define the skeleton.*

#### **3.2.2 Word**

**key**  
**SOUS\_STRUC**

**SOUS\_STRUC**

*Key word factor for the creation of a skeleton following a calculation by dynamic under-structuring traditional.*

*Allows to define on each substructure of the model generalized the list of the meshes of visualization.*

### **3.2.2.1 Operand**

**NAME**

*NAME = nom\_struc*

*Name of the substructure. It must be identical to the one of the names of the substructures defining it generalized model (see **DEFI\_MODELE\_GENE** [U4.65.02]).*

*Instruction manual*

*U4.2- booklet: Grid HT-66/05/004/A*

*Author (S):*

**O. NICOLAS, E. BOYERE** *Key*

:

*U4.24.01-H Page*

: 4/6

### **3.2.2.2 Operands**

**ALL/MESH/GROUP\_MA**

/

**ALL**

*All the meshes of the grid of the substructure will be meshes of visualization.*

*/| MESH*

*=*

*filed*

*List meshes of visualization of the substructure.*

*/*  
*GROUP\_MA = grma*

*List groups of meshes of visualization of the substructure.*

### **3.3 Word**

*key*

**GRID**

*It is about a functionality for the Aster/CADYRO interface (software of dynamic analysis of the lines of revolving shaft). That makes it possible to visualize a modal deformation on whole or part grid given under the key word GRID.*

#### **3.3.1 Operands**

**NET/GROUP\_MA/ALL**

*These key words specify the parts of the grid on which one wants to visualize the modal deformation.*

#### **3.3.2 Operand**

**TRANS**

*List of 3 realities giving the co-ordinates of the vector translation applied to the characterized structure by the grid given (if this one has a final position different from its initial position).*

#### **3.3.3 Operand**

**ANGL\_NAUT**

*List of 3 realities giving the 3 nautical angles allowing to make a rotation of the grid of structure if necessary.*

**Note:**

*When one wishes to print the skeleton thereafter with the order IMPR\_MACR\_ELEM with format CADYRO, only triplattes of nautical angles (0, 0, 0), (0, 90, 0) or (0, 90, 180) are accepted.*

### **3.4 Words**

## **keys**

### ***SKELETON and RECO\_GLOBAL***

*The key word SKELETON defines an initial concept of skeleton type where one will amalgamate the nodes of*

*interfaces by key word RECO\_GLOBAL, either all these nodes (ALL = "YES"), or selectively one group nodes grno1 (operand GROUP\_NO\_1) of the substructure nom\_sstru1 (operand SOUS\_STRUC\_1) with a group of nodes grno2 (operand GROUP\_NO\_2) of the substructure nom\_sstru2 (operand SOUS\_STRUC\_2).*

*These substructures must belong to the concept of the modele\_gene type informed by the operand MODELE\_GENE.*

*The skeleton modified by fusion will be the result of operator DEFI\_SQUELETTE.*

### **3.4.1 Operands DIST\_REFE/CRITERION/PRECISION**

*Fusion will be made according to a criterion of proximity either absolute (compared to dist\_ref) or relative (by report/ratio with dist\_ref\*prec).*

## **3.5 Word**

### **key**

#### ***NOM\_GROUP\_MA***

*If one modifies an initial concept of skeleton type (entered by the key word SKELETON) by a fusion of the nodes of the interfaces (by means of key word RECO\_GLOBAL), one can then recover groups of meshes (entered by operand GROUP\_MA) in the substructure nomsst (entered by operand SOUS\_STRUC) in their naming new of group of meshes (operand NAME) in the skeleton result.*

### **3 Operands**

#### **3.1 Key word**

**FAISCEAU\_TRANS**

**/FAISCEAU\_TRANS**

*Key word factor allowing to characterize a configuration of the type “beam of tubes under transverse flow”. If the study is based on the definition of several zones of excitation, it as many occurrences of the key word factor FAISCEAU\_TRANS of zones is necessary.*

**COUPLING = “YES” or “NOT”**

*Indicator of the type text [TXM] specifying the taking into account or not forces fluid-rubber bands. This operand must appear in at least one of the occurrences of key word factor FAISCEAU\_TRANS, and can be omitted in the others.*

**CARA\_ELEM = will cara**

*Concept of the type [cara\_elem] allowing to provide all the data relative to geometry of the elements of the structure: useful for the estimate of the hydraulic diameter. This operand must appear in at least one of the occurrences of the key word factor FAISCEAU\_TRANS, and can be omitted in the others.*

**PROF\_VITE\_FLUI = profv**

*Concept of the type [function] allowing to provide the adimensionné profile speed transverse along the tube. The parameter of the function is the curvilinear X-coordinate. This operand must appear in all the occurrences of the key word factor FAISCEAU\_TRANS.*

**PROF\_RHO\_F\_INT = profrhoi**

*Concept of the type [function] allowing to provide the profile of density of fluid interns with the tube, along the tube. The parameter of the function is the X-coordinate curvilinear. This operand must appear in at least one of the occurrences of the word key factor FAISCEAU\_TRANS, and can be omitted in the others.*

*PROF\_RHO\_F\_EXT = profrhoe*

*Concept of the type [function] allowing to provide the profile of density of external fluid with the tube, the tube. The parameter of the function is the X-coordinate curvilinear. This operand must appear in at least one of the occurrences of the word key factor FAISCEAU\_TRANS, and can be omitted in the others.*

*NOM\_CMP = "DX" or "DY" or "DZ"*

*Indicator of the type text [TXM] specifying the direction according to which the forces act fluid-rubber bands and/or turbulent forces. This operand must appear in with less one of the occurrences of the key word factor FAISCEAU\_TRANS, and can be omitted in the others.*

:

*U4.25.01-G1 Page:*

5/20

*COEF\_MASS\_AJOU = cm*

*Value of the coefficient of added mass cm. This operand, if it is used, can not be defined that in one of the occurrences of the key word factor FAISCEAU\_TRANS, and can to be omitted in the others.*

*CSTE\_CONNORS*

=

*cste*

*List of two realities defining the interval of the constants of Connors for the method of even name (see R4.07.04).*

*RHO\_TUBE*

=

*rho*

*Density of the tube for the method of Connors*

*NB\_CONNORS = Nb*

,

*[I]*

*Poins of discretization inside the interval numbers defined by the key word CSTE\_CONNORS presented above.*

/

*TYPE\_PAS = “CARRE\_LIGN” or “TRIA\_LIGN”*

*Indicator of the type text [TXM] allowing to specify the type of step of beam, defined by the arrangement of the tubes the ones compared to the others and by the direction of the flow compared to the beam. This operand can appear only in one of the occurrences of the key word factor FAISCEAU\_TRANS, and can be omitted in the others.*

*“CARRE\_LIGN” = not square line.*

*“TRIA\_LIGN” = not triangular line.*

*TYPE\_RESEAU = tr*

*Whole indicator strictly lower than 1000 and positive defining experimental configuration for which coefficients of coupling used for the study were obtained [bib1]. This operand must appear in all occurrences of the key word factor FAISCEAU\_TRANS.*

**Note:**

*“tr” must appear in two files “cd.70” and “ck.71” which allows to describe the evolution of damping and the stiffness added by the flow according to the fallback speed Vr, the latter being calculated from speed inter-tubes.*

*The files “cd.70” and “ck.71” are read by the logical units 70 and 71. They have both the following structure:*

***Line 1 of the file:*** a number of correlations present as a whole of file (whole)

*\*\*\* then, for each one of these correlations, a block made up of \*\*\**

***Line 1 of the block:*** type of step of the network associated with the correlation (1 if TYPE\_PAS= “CARRE\_LIGN”, 2 if TYPE\_PAS= “TRIA\_LIGN”)

***Line 2 of the block***

*: tr (whole well informed on the level of the operand “TYPE\_RESEAU”)*

***Line 3 of the block:*** nbplages (a number of contiguous beaches fallback speed on which added damping and the stiffness were interpolated by the user in polynomial form)

**Line 4 of the block:** *nbplages real, followed from two real A and B; nbplages the first realities correspond to the values fallback speed - ordinates by order ascending - lower limits of the contiguous nbplages; two realities With and B are respectively smallest and largest values speed*

*:*

*U4.25.01-G1 Page:*

*6/20*

*reduced for which added damping and the stiffness were given in experiments on a test bench in thermohydraulic similarity; they thus delimit the beach fallback speeds inside which correlation can be interpolated starting from the values identified on test bench. In general, one thus chooses the first of the real nbplages equal to A and the last real nbplages equal to B.*

**Nbplages following lines**

*: each line corresponds to the interpolation*

*polynomial of the correlation of damping or the stiffness added in beach considered, the first beach fallback speeds extending between first and the second of the real nbplages. On each line, 11 coefficients are to inform. These coefficients are them (I)  $l_i$  11*

*defining the polynomial used*

*for the interpolation in the beach considered. Thus, for the example, indicating  $C_d$  the damping added by the flow. The expression which will be taken by it in count according to the fallback speed  $V_r$  is as follows (the expression for added stiffness is similar):*

$C_d(V_r)$  11

*(i-4)*

= I Vr

i=1

Following line: a line allowing to delimit the blocks associated with each correlation, in general of the form: “\*\*\*\*\*”

\*\*\* fine of the block \*\*\*

If there are other correlations, Ligne 1 of the block corresponding to the correlation following.

On the basis of number certain of tests, EDF worked out and validated a unit correlations fluid-rubber bands allowing to simulate damping and stiffness added to a structure by a flow. Supply of these correlations in the shape of two files of a format conforms with that specified Ci high will be studied on a case-by-case basis according to the request.

NOT = not

Step value reduced of the beam: report/ratio enters, on the one hand the distance between centres between 2

close tubes, and in addition the diameter external of the tubes. This operand can appear only in one of the occurrences of the key word factor FAISCEAU\_TRANS, and can be omitted in the others.

### **3.2 Key word**

#### **BUNCH**

/BUNCH

Key word factor allowing to characterize a configuration of the type “control rod”.

COUPLING = “YES” or “NOT”

Indicator of the type text [TXM] specifying the taking into account of the forces fluid-rubber bands. The coupling fluid-rubber band, if it is taken into account, utilizes the coefficients adimensional of forces fluid-rubber bands identified on model GRAPPE2, which are used to represent a resulting force and a moment [bib2].

If COUPLING = “YES”, it is necessary to inform the following operands obligatorily, with exception of COEF\_MASS\_AJOU which remains optional.

*/GRAPPE\_2 = "ASC\_CEN" or "ASC\_EXC" or "DES\_CEN" or "DES\_EXC"*

*Four possible choices corresponding to the various configurations experimental for which the coefficients of forces fluid-rubber bands have summer identified:*

.

*ascending flow stem of Centered order;*

.

*ascending flow stem of Offset order;*

.

*flow Descending stem from Centered order;*

.

*flow Descending stem from Offset order.*

*NODE = No*

*Identifier of the node (concept of the type [node]) where are applied the force and moment resulting representing the action from the forces fluid-rubber bands.*

*CARA\_ELEM = will cara*

*Concept of the type [cara\_elem] providing all the data relative to geometry of the elements of the structure: useful for the estimate of the diameter of stem of order. This concept brings inter alia relative information with the orientations of the elements.*

*MODEL = model*

*Concept of the type [model] providing information relating to the types of elements of the structure.*

$COEF\_MASS\_AJOU = cm1$

*Value of the coefficient of added mass due to the local containment of the stem of order on the level of the plate of housing. If modal characteristics out of water at rest of the structure were calculated with the density equivalent.*

2

$D$   
 $eq =$   
 $water + beam$   
 $4S$

*The coefficient  $cm1$  of mass added due to local containment to the level of plate housing is given by the relation:*

$(D$   
 $-$   
 $2H$   
 $)$   
 $cm1 =$

2

*where  $D$  indicates the diameter external of the stem;  $S$  is the surface of the cross-section tube and  $H$  represent the thickness of fluid film on the level of containment.*

**Note:**

*When the user does not inform operand  $COEF\_MASS\_AJOU$ ,  $cm1$  is estimated automatically using this expression with  $= 1$ .*

$RHO\_FLUI = rho\_f$

*Value of the density of the fluid surrounding the structure.*

### **3.3 Key word**

**FAISCEAU\_AXIAL**

*/FAISCEAU\_AXIAL*

*Key word factor allowing to characterize a configuration of the type “beam of tubes under axial flow” [bib2].*

**Note:**

*If the study is carried out using a representation of the complete beam, one authorize only one occurrence for this key word factor.*

*If the study is based on a simplified representation, one needs as many occurrences as there is tubes in the simplified beam. Each tube of the simplified beam defines a class of equivalence for the tubes of the real beam. Characteristics of the tubes of the beam reality for the same class of equivalence (common ray, positions) are the subject of one occurrence of the key word factor.*

*To be able to use a simplified representation of the beam, it is necessary that the modal base calculated in air is equivalent to the modal base in air complete of the real beam; each tube of the simplified beam must thus be a tube equivalent to each class of real tubes. For example, for a class of NR real tubes, Young modulus E and of density, a possible equivalent tube is characterized by a Young modulus And a density NR.*

*/GROUP\_MA = l\_grma*

*If the study relates to the complete beam: list groups of meshes corresponding to the tubes of the beam (concepts of the type [group\_ma]).*

*If the study is based on a simplified representation: the use of this operand is obligatory and excludes the recourse to TRI\_GROUP\_MA. One is awaited concept of the type [group\_ma] corresponding to the one of the equivalent tubes of simplified beam.*

/

*TRI\_GROUP\_MA = "racine\*" or "\*racine\*" or "\*racine"*

*Argument of the type text [TXM] defining the root of the names of the groups of meshes corresponding to the tubes of the beam. The use of this operand is not sell by auction that if the study is carried out using a representation of the beam complete. The root can be a prefix, an intermediate character string or a suffix.*

*VECT\_X = l\_comp*

*List of three realities giving the components of the directing vector of the beam in total reference mark. The beam having to be directed according to one of the axes of the total reference mark, only three sets of components are acceptable: (1. , 0. , 0.) , (0. , 1. , 0.) or (0. , 0. , 1.). This operand is obligatory if the study relates to the complete beam, and must appear with less in one of the occurrences of the key word factor if the study rests on one simplified representation.*

*PROF\_RHO\_FLUI = profrho*

*Concept of the type [function] defining the profile of density of the fluid surrounding the tubes. The parameter of the function is the co-ordinate of space corresponding to the axis of the total reference mark directing the beam of tubes. This operand is obligatory if the study relates to the complete beam, and must appear at least in one occurrences of the key word factor if the study is based on a simplified representation.*

*PROF\_VISC\_CINE = profvisc*

*Concept of the type [function] defining the kinematic profile of viscosity of the fluid surrounding the tubes. The parameter of the function is the co-ordinate of space corresponding to the axis of the total reference mark directing the beam of tubes. This operand is obligatory if the study relates to the complete beam, and must appear at least in one occurrences of the key word factor if the study is based on a simplified representation.*

*/CARA\_ELEM = will cara*

*Concept of the type [cara\_elem] providing all the data relative to geometry of the elements of the structure: ray of each tube. This concept is to be provided only if the study relates to the complete beam.*

*/*  
*RAYON\_TUBE = ray*

*Ray of the tubes of the real beam for the same class of equivalence. This operand is used only if the study rests on one simplified representation.*

*COOR\_TUBE = l\_coor*

*List co-ordinates of the centers of the tubes of the real beam pertaining to the same class of equivalence. This operand is used only in the case where the study is based on a simplified representation.*

*GRAVITY = l\_g*

*List of four realities defining the standard and the orientation of the vector gravity **G** in total reference mark. It is necessary to provide in the order the data (G, ap, LP, CP) such as:*

*p X + LP Y has + CP Z*  
***G** = G*

*a2*  
*2*  
*2*  
*p + B p + C p*

*The default values are: G = 9.81; ap = 0. ; LP = 0. ; CP = 1.*

*RUGO\_TUBE = rug*

*Value of the absolute roughness of the walls of the tubes, being used for the estimate of the coefficient of axial friction. This operand is obligatory if the study relates to the beam complete, and must appear at least in one of the occurrences of the key word factor if the study is based on a simplified representation. A characteristic value for one smooth steel is 105 meter.*

*CARA\_PAROI = will l\_cara*

*List arguments of the type text [TXM] giving the names of the characteristics geometrical of the enclosure wrapping the beam. The licit arguments are them following:*

*.  
“YC”, “ZC” and “R” in the case of a circular enclosure: “YC”, “ZC”  
co-ordinates of the center in any plan  $X = x_0$  along the axes of the total reference mark perpendiculars with the beam and ordered such as (X, Y, Z) is direct if X is the axis of the total reference mark directed according to the beam. “R” ray.*

*.  
“YC”, “ZC”, “HY” and “HZ” in the case of a rectangular enclosure: “YC”,  
Coordinated “ZC” of the center in any plan  $X = x_0$ . “HY”, “HZ” dimensions of sides of the enclosure parallel respectively with the directions Y and Z.*

*VALE\_PAROI = l\_vale*

*List realities giving the values of the geometrical characteristics, in correspondence with the list of the names received for CARA\_PAROI.*

$ANGL\_VRIL = \alpha$

*Swing angle (in degrees) around the directing axis of the beam for an enclosure rectangular. This operand is obligatory if one defines a rectangular enclosure by CARA\_PAROI and VALE\_PAROI. It is prohibited in the case of a circular enclosure.*

**Note:**

*Operands CARA\_PAROI and VALE\_PAROI are obligatory when the study carries on the complete beam. When the study is based on a simplified representation, these operands must appear together in at least one of the occurrences of key word factor FAISCEAU\_AXIAL. Operand ANGL\_VRIL must also be present under the same occurrence if a rectangular enclosure is defined.*

**Example:**

Total reference mark (X, y,)

Z beam axis y

X

HY

HZ

ZC

alpha

YC

Z

**Note:**

*If the study is carried out with the taking into account of the grids of the beam tubes, the user must inform each of the eight operands which follow. One recall that the geometry of a grid is a prismatic network at square base. It can exist several types of grid; for example, grids of end and them grids of mixture in the fuel assemblies. Grids of the same type are characterized by identical dimensions and coefficients.*

$LONG\_TYPG = l\_hg$

*List realities giving the lengths of each type of grid of the beam of tubes. length of a grid is its dimension according to the direction of the beam.*

$LARG\_TYPG = l\_dg$

*List realities giving the widths of each type of grid. The width of a grid is its*

*dimension in the plan perpendicular to the beam axis (i.e. the length of dimensioned network).*

$$EPAIS\_TYPG = l\_tg$$

*List realities giving the thicknesses of each type of grid. What is called thickness of grid, it is the thickness of the network constituting the grid in a section perpendicular with the beam axis.*

31/01/06

*Author (S):*

**A. Key ADOBES**

:

*U4.25.01-G1 Page:*

13/20

**Note:**

1)

*Values of the various average singular loss ratios of load and*

dynamic are given, in complements, for various configurations geometrical usual of entry and exit (see hereafter [§6]).

2) By convention, a mean velocity of flow positive means that the flow is done in the direction growing of the parameter of space along the axis of revolution of the structures. Contrary, a mean velocity of flow negative means that the flow is done in the direction decreasing of the parameter of space. The sign mean velocity of flow thus fixes the positions of entry and exit. So that there is no ambiguity on these positions, one will take care in `CALC_FLUI_STRU` [U4.80.03] to define a beach of the same speeds signs.

3)  
Model `MOCCA_COQUE` used for the resolution of the coupling fluid-structure require, for each mode selected, to identify the order of hull on the deformation.

`NR`  
The identifiable orders of hull  $k_i$  are such as:  $k_i$   
where `NR` indicates it

2  
a number of nodes of the grid on a circumference, i.e at a fixed altitude.

`NR`  
orders of hull  $k_i$  precisely identified are such as  $k_i$   
, with the same one

4  
definition for `NR`.  
One advises to use a grid with at least 20 nodes on the circumferences hulls. A minimum number of 8 nodes is necessary.

### **3.5 Key word INFORMATION**

`INFORMATION` = 1 or 2

Level of impression.  
If `INFORMATION` = 2 one prints the characteristics of the configuration in the file `MESSAGE`.  
If `INFORMATION` = 1 step of impression.

**3 Operands**

**3.1 Operand**

**NOM\_RESU**

**NOM\_RESU = NR**

**Indicate the name of the result, the function thus created is a function whose value is of name NR (8 characters).**

*In fact, this operand is not useful systematically for checks of coherence, in execution of the code. These checks of coherence are made by the order CALC\_FONCTION.*

### **3.2 Operand**

**VALE**

**VALE = v**

*Value of the constant (a real number).*

### **3.3 Operand**

**TITRATE**

**TITRATE = Ti**

*Titrate attached to the concept produced by this operator [U4.03.01].*

### **4 Examples**

.

*To define the constant function “1.” :*

**F\_UN = DEFI\_CONSTANTE (  
VALE = 1. )**

*Function F\_UN represents “any kind of result” (TOUTRESU) per DEFECT*

.

*To define a constant function representing a constant YOUNG modulus*

**F\_YOUNG =  
DEFI\_CONSTANTE  
(**

**VALE = 2.1E11,  
NOM\_RESU**

**=  
“E”  
)**

**:**

**3 Operands**

**3.1 Operand**

**NOM\_PARA**

**NOM\_PARA =  $N_p$**

**Indicate the name of the parameter (variable or X-coordinate) of the function.**

**The possible values for  $N_p$  are:**

**“TEMP”**

**“INST”**

**“EPSI”**

**“SIGM” “META”**

**“X”**

**“Y”**

**“Z”**

**“FREQ”**

**“PULS”**

**“AMOR”**

**“ABSC” “DSP”**

**“DX”**

**“DY”**

**“DZ”**

**“DRX”**

**“DRY”**

**“DRZ”**

**“HYDR”**

**“SECH”**

**“PORO”**

**“SAT” “PGAZ”**

**“PCAP”**

**“QUICKLY” “ENDO”**

**“NORM”**

*This list is not exhaustive, the user can choose the name of its parameter (cf notices in NOM\_RESU).*

### **3.2 Operand**

**NOM\_RESU**

**NOM\_RESU = NR**

*Indicate the name of the result (8 characters). The function thus created is  $NR = F(Np)$ .*

**Note:**

*Certain orders (CALC\_FONCTION, DEFI\_MATERIAU...) check coherence names of the parameter and result according to their context. For example, one a traction diagram defined by a function waits of which  $NOM\_PARA = 'EPSI'$  and  $NOM\_RESU = 'SIGM'$ .*

### **3.3 Operand**

**VALE**

**/VALE = lv**

*lv is the list of values ( $x1, y1, \dots, xn, yn$ ) with in the order:*

*.  
X  
(the first value of the parameter and the corresponding value of the result),  
1, y1  
... ,  
.  
X  
(the last value of the parameter and the corresponding value of the result).  
N, yn*

**Note:**

*The list lv of values must be described in the order of the X-coordinates (X) increasing.*

### **3.4 Operand**

**VALE\_C**

**/VALE\_C = lv**

*lv is the list of the values (X, y, Z,..., xn, yn, Zn) with:*

*.  
xi values of the parameter*

*... ,*

*.*

*y*

*the real part and the imaginary part of the function complex for it*

*I, zi*

*parameter.*

*Instruction manual*

*:*

*U4.31.02-II Page:*

*4/8*

**3.5 Operand**

**VALE\_PARA**

**/VALE\_PARA =**

*is the list of the values of the parameter Np (X-coordinates): it is a concept of the listr8 type created previously by order DEFI\_LIST\_REEL [U4.34.01].*

**3.6 Operand**

**VALE\_FONC**

***/VALE\_FONC = lo***

*lo is the list of the values of the parameter NR (ordered): it is a concept of the listr8 type created previously by order DEFI\_LIST\_REEL [U4.34.01].*

*VALE\_PARA and VALE\_FONC must be identical cardinals if not the order stops in error.*

### **3.7 Operand**

***NOEUD\_PARA***

***/NOEUD\_PARA = lno***

*lno list of nodes allowing to define the values of the X-coordinates of the function to be defined.*

*The X-coordinates will be equal to the curvilinear X-coordinates of the nodes on the curve that they define.*

### **3.8 Operands**

***PROL\_DROITE and PROL\_GAUCHE***

***PROL\_DROITE and PROL\_GAUCHE =***

*Define the type of prolongation on the right (on the left) of the field of definition of the variable:*

•  
*“CONSTANT” for a prolongation with the last (or first) value of function,*

•  
*“LINEAR” for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),*

•  
*“EXCLUDED” if the extrapolation of the values apart from the field of definition of parameter is prohibited (in this case if a calculation requires a value function out of the field of definition, the code will stop in fatal error).*

*For example:*

•  
***PROL\_DROITE = “CONSTANT”, PROL\_GAUCHE = “CONSTANT”***

*y*  
*X*

*X*  
*X*  
*X*  
*X*  
*1*  
*2*  
*n-1*  
*N*

*Version*  
*8.2*

*Titrate:*  
*Operator DEFI\_FONCTION*

*Date:*  
*02/03/06*  
*Author (S):*  
*Key COURTEOUS Mr.*  
*:*  
*U4.31.02-II Page:*  
*5/8*

*.*  
*PROL\_DROITE = "LINEAR", PROL\_GAUCHE = "EXCLUDED"*

*y*  
*X*  
*X*  
*X*  
*X*  
*1*  
*x2*  
*n-1*  
*N*

*Note:*

*The type of prolongation and interpolation are independent one of the other.*

### **3.9 Operand**

#### **Interpol**

#### **Interpol**

=

*Type of interpolation of the function enters the values of the field of definition of the function: one type for the interpolation of the parameter and for the interpolation of the function. This is obtained in*

*providing a list of texts among:*

#### **Interpol**

=

*(“FLAX”,  
“LOG”)*

*“FLAX”: linear,*

*“LOG”: logarithmic curve,*

*“NOT”: one does not interpolate (and thus the program will stop if for the value is asked function for a value of the parameter where it was not defined).*

*Note:*

*If only one value is specified, it is taken into account at the same time by the interpolation of parameter and of the function. Interpol = “LOG” is equivalent to (“LOG”, “LOG”).*

### **3.10 Operand**

#### **INFORMATION**

#### **INFORMATION**

=

*Specify the options of impression on the file MESSAGE.*

*1: no the impression (default option)*

*2: impression of the parameters plus the list of the first 10 values in the ascending order parameter*

### **3.11 Operand**

#### **VERIF**

#### **VERIF**

=

**Operator *DEFI\_FONCTION* checks that the values of the X-coordinates are strictly increasing. If it is not the case, an error is started. This is the behavior by defect, *VERIF* is worth "GROWING".**

**The user with the possibility of not making this checking by indicating *VERIF*='NON'. In it case, one does not start an error and the function is reordered by increasing X-coordinates.**

**T**  
**-1**  
**PROL DROITE=' LINEAIRE',**  
**);**

#### **4.2**

**Function and variables entered in the form of concepts listr8**

.

**It is possible to define this function using concepts of the listr8 type created by the intermediary of operator *DEFI\_LIST\_REEL* [U4.34.01]:**

***X-COORDINATE = DEFI\_LIST\_REEL (BEGINNING = 0. ,***

***INTERVAL = (\_F (JUSQU\_A = 1. , A NUMBER = 1),***

***\_F***  
***(***  
***JUSQU\_A***  
***=***  
***3.,***  
***NUMBERS***  
***=***  
***1),***

***\_F***  
***(***  
***JUSQU\_A***  
***=***  
***6.,***  
***NUMBERS***  
***=***  
***1,))***

)

*ORDINATE = DEFI\_LIST\_REEL (BEGINNING = -1. ,*

*INTERVAL = (\_F (JUSQU\_A = 0. , A NUMBER = 1),*

*\_F  
(JUSQU\_A  
=  
1.,  
NUMBERS  
=  
1),*

*\_F  
(JUSQU\_A  
=  
2.,  
NUMBERS  
=  
1),)*

)

**EX\_2 = DEFI\_FONCTION**  
**(NOM\_PARA = "INST",**  
**VALE\_PARA**

**=**  
**X-COORDINATE,**  
**VALE\_FONC**

**=**  
**ORDINATE,**  
**PROL\_DROITE**

**=**  
**"CONSTANT",**  
**PROL\_GAUCHE**

**=**  
**"LINEAR",**

)

**Note:**

*The second example is obviously quite complicated to define the function suggested. We wanted only to highlight the principle of use of the possibility offered.*

*This one becomes interesting when one uses functions defined in large a number of points.*

*Another reason to use the definition by DEFI\_LIST\_REEL is when the lists are necessary like argument for another operator: (list of the moments of a calculation evolutionary THER\_LINEAIRE, DYNA\_LINE\_TRAN,...), this avoids duplication then information.*

### **3 Operands**

#### **3.1 Operand**

**NOM\_PARA**

**NOM\_PARA = Np**

**Indicate the name of the parameter of the tablecloth (second variable) cf example with [§4.1].**

**The values currently authorized for Np are:**

**/“TEMP”**

**/“INST”**

**/“X”**

**/“Y”**

**/“Z”**

**/“FREQ”**

**/“PULS”**

**/“AMOR”**

**/“THICK”**

**/“TSEC”**

**/“HYDR”**

**/“SECH”**

#### **3.2 Operand**

## ***NOM\_RESU***

***NOM\_RESU = NR***

***Name of the result, the values of the tablecloth.***

***In fact, this operand is not useful systematically for checks of coherence, in execution of the code. These checks of coherence are made by the order CALC\_FONCTION [U4.32.04].***

## ***3.3 Operand***

***PARA***

***PARA = LP***

***List values of the parameter characteristic of the tablecloth: para1, para2,... the cardinal of this list must be equal to the number of functions defined then.***

## ***3.4 Operands***

***PROL\_DROITE and PROL\_GAUCHE***

***PROL\_DROITE and PROL\_GAUCHE =***

***Define the type of prolongation on the right (on the left) of the field of definition of the variable:***

***“CONSTANT”***

***for a prolongation with the last (or first) value of the tablecloth,***

***“LINEAR”***

***for a prolongation along the first definite segment (LEFT PROL)***

***or of the last definite segment (PROL\_DROITE), this prolongation does not hold not account of a possible interpolation logarithmic curve,***

***“EXCLUDED”***

***if the extrapolation of the values apart from the field of definition of parameter  $N_p$  is prohibited (in this case if a calculation requires a value function out of the field of definition, the code will stop in error fatal).***

## ***3.5 Operand***

***Interpol***

***Interpol***

***=***

***Type of interpolation of the function enters the values of the field of definition of the function: one type for the interpolation of the parameter and for the interpolation of the function. This is obtained***

*in*  
*providing a list of 2 texts among:*

*Interpol*  
=  
("FLAX",  
"LOG")  
"FLAX": linear,  
"LOG": logarithmic curve,  
"NOT": one does not interpolate (and thus the program will stop if for the value is asked  
function for a value of the parameter where it was not defined).

*Instruction manual*  
*U4.3- booklet: Function*

*Author (S):*  
*COURTEOUS Mr., J.P. LEFEBVRE Key*  
:  
*U4.31.03-H Page*  
: *4/6*

*Note:*  
*If only one value is specified, it is taken into account at the same time by the interpolation of  
parameter and of the function. Interpol = "LOG" is equivalent to ("LOG", "LOG").*

*3.6 Operand*  
*INFORMATION*

*INFORMATION*  
=

*Specify the options of impression on the file message (unit 6).*

**1 :**

*no the impression (default option)*

**2 :**

*impression of the parameters plus the list of the first 10 values of each function in the order ascending of the the first 10 parameter*

### **3.7 Operand**

**VERIF**

**VERIF**

=

*Operator **DEFI\_NAPPE** reorders the values of the parameters  $N_p$  in the ascending order. If **VERIF** is worth "GROWING" the operator stops the execution if the values of the parameter  $N_p$  do not have summer given in this order.*

### **3.8**

*Definition of the functions of the tablecloth*

*Two modes of definition of the tablecloth are possible:*

.

*starting from a list of existing functions [§3.8.1],*

.

*by directly defining the various functions of the tablecloth [§3.8.2].*

#### **3.8.1 Operand**

**FUNCTION**

**FUNCTION = lf**

*List concepts of the function type created by orders **DEFI\_FONCTION** [U4.31.02], **DEFI\_CONSTANTE** [U4.31.01], **CALC\_FONC\_INTERP** [U4.32.01],...*

*lf is the list of the names of concepts of the function type corresponding to the values of the parameter.*

*All the functions of the list must have the same name of variable (that we will call  $npf$ ) and to have the same name  $NR$  for name of result.*

*nf is a tablecloth of the variable of name  $N_p$  and variable of name  $npf$  and whose value is of name  $NR$ .*

#### **3.8.2 Definition**

*direct of the functions*

### **3.8.2.1 Operand**

**NOM\_PARA\_FONC**

**NOM\_PARA\_FONC**

**= npf**

**Name of the parameter characteristic of the functions constituting the tablecloth.**

**The values currently authorized for npf are:**

**/“TEMP”**

**/“INST”**

**/“X”**

**/“Y”**

**/“Z”**

**/“EPSI”**

**/“FREQ”**

**/“PULS”**

**/“AMOR”**

**/“THICK”**

**/“SAT”/“PGAL”**

**/“PCAP”**

**: 5/6**

### 3.8.2.2 Word

*key*

***DEFI\_FONCTION***

***DEFI\_FONCTION =***

*Direct definition of the functions constituting the tablecloth.*

### 3.8.2.3 Operand

***VALE***

***VALE = lv***

*lv is the list of value (x1, y1, ..., xn, yn) with in the order:*

***X***

*(the first value of the parameter and the corresponding value of the result),*

***1, y1***

***...***

***X***

*(the last value of the parameter and the corresponding value of the result).*

***N, yn***

### 3.8.2.4 Operands

***PROL\_DROITE and PROL\_GAUCHE***

***PROL\_DROITE***

***and PROL\_GAUCHE =***

*Define the type of prolongation on the right (on the left) of the field of definition of variable:*

***“CONSTANT”***

*for a prolongation with the last (or first) value of function,*

***“LINEAR”***

*for a prolongation along the first definite segment*

*(PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),*

***“EXCLUDED”***

*if the extrapolation of the values apart from the field of definition of*

*parameter npf is prohibited (in this case if a calculation requires one value of the function out of the field of definition, the code will stop in fatal error).*

*function nf  
parameter Np  
function f2  
parameter para2  
function f1  
parameter para1  
variable npf*

### **3.8.2.5 Operand Interpol**

*Interpol  
=*

*Type of interpolation of the function enters the values of the field of definition of the function: one type for the interpolation of the parameter and for the interpolation of the function. This is obtained in providing a list of texts among:*

*Interpol  
=  
("FLAX",  
"LOG")  
"FLAX": linear,  
"LOG": logarithmic curve,  
"NOT": one does not interpolate (and thus the program will stop if for the value is asked function for a value of the parameter where it was not defined).*

## **U4.31.05-G1 Page:**

**3/6**

### **3 Operands**

#### **3.1**

**Definition of the function, key word VALE**

**The body of the function is an algebraical expression PYTHON represented by a chain of characters. It must be appraisable in the context: thus to respect syntax PYTHON and not to use that functions, methods or constants defined before the moment of its evaluation.**

**In the event of error of syntax, it is the language PYTHON which transmits the error message and not Code\_Aster itself.**

#### **3.2 Functions**

**standards**

**For a formula represented by an ordinary algebraic function, to refer to:**

**“Using PYTHON have has calculator”, paragraph [§3.1.1]**

**<http://docs.python.org/tut/tut.html>**

**In addition to the ordinary algebraical signs + -/\*\*\*, functions standards are also available (buildins): min, max, ABS, float...**

**Attention, the sign of division indicates real division here:**

$$1 / 2 = 0.5$$

**If one wishes to make a whole division operation, should be used the // operator:**

$$1 // 2 = 0$$

#### **3.3 Functions**

**mathematics**

**The principal functions of the module maths of PYTHON are imported by defect. They are thus directly usable in the body of the formulas.**

**<http://docs.python.org/lib/module-math.html>**

**sin sinh**

**cos cosh**

**tan tanh**

**atan sqrt**

**atan2 log**

*asin log10*  
*acos exp*

*Moreover, constant pi, same module, is also available.*

**Caution:**

*The goniometrical functions are thus those of PYTHON and await angles expressed in radians. It is necessary to be vigilant on coherence with single-ended spanner words ANGL\_\* of the language of order which requires angles in degrees in general.*

*One can use others of them by taking care to before import them the declaration of formulate. Example of redefinition of the exponential one:*

```
from maths importation E, pow  
f_exp = FORMULA (NOM_PARA=' X', VALE=' pow (E, X) ')
```

*Instruction manual*

*U4.3- booklet: Function*

**C. Key DURAND**

:

*U4.31.05-G1 Page:*

4/6

**4 Examples  
of use**

*For various examples one will refer to the case test ZZZZ100A.*

**4.1**

***A formula is used like a tabulée function***

*Definition of the Sia formula:*

$Sia = FORMULA (NOM\_PARA=' X', VALE=' sin (X) ')$

$LR = DEFI\_LIST\_REEL (BEGINNING = 0. ,$   
 $INTERVAL = \_F (JUSQU\_A = pi, NOT = 0.01))$

*Equivalent tabulée function IF:*

$IF = CALC\_FONC\_INTERP (FUNCTION = Sia,$   
 $LIST\_PARA = LR,$   
 $NOM\_PARA = "X",$   
 $NOM\_RESU = "DEPL",)$

*To thus define a function tabulée starting from an interpretable formula, to see CALC\_FONC\_INTERP [U4.32.01].*

*Use of IF or of Sia in a single-ended spanner word awaiting a function or a formula:*

$champ=CREA\_CHAMP (... AFFE = \_F (... VALE\_F = IF or Sia,))$

## 4.2

***A formula can be evaluated like a reality***

*In the body of the command file:*

$Sia = FORMULA (NOM\_PARA=' X', VALE=' sin (X) ')$

$X = Sia (1.57)$

$print Sia (1.57)$

*Behind a single-ended spanner word awaiting a reality:*

$LR = DEFI\_LIST\_REEL (BEGINNING = Sia (0.),$   
 $INTERVAL = \_F (JUSQU\_A = Sia (pi/2.), NOT = 0.01))$

*In another formula:*

$Sib = FORMULA (NOM\_PARA=' X', VALE=' X*Sia (5.)')$

## 4.3

***To call upon a formula in another formula***

$SIa = FORMULA (NOM\_PARA=' X', VALE=' \sin (X) ')$

$SIb = FORMULA (NOM\_PARA=' X', VALE=' X*SIa (X) ')$

*Instruction manual*

*U4.3- booklet: Function*

*Author (S):*

**C. Key DURAND**

:

*U4.31.05-G1 Page:*

*5/6*

## **4.4**

### ***Formulate with several parameters***

$NAP = FORMULA (NOM\_PARA = ("FREQ", "AMOR"),$

$VALE = " (1. /((2. *pi * FREQ) ** 2 - OMEGA ** 2) ** 2$

$+ (2. *AMOR * 2. *pi * FREQ * OMEGA) ** 2) "$ )

*In this example, one defines a formula in 3 parameters. Taking into account the length of the expression, it is written for more convenience on several lines with triple dimensions to delimit it.*

*constant pi is constant a standard (cf paragraph [§3.2]), the OMEGA constant will have been defined higher by the user.*

*In the current state, only the formulas of RN in R are possible: only one produced reality.*

## **4.5**

### ***Formulate resulting from programming of function PYTHON***

*One can refer in a formula to functions programmed in PYTHON, which authorizes formulas much more complex than of simple algebraical expressions.*

*For example a function of Heavyside:*

*0 if X*

*.*

*<*

*0*

*HEAVYSIDE (X) =*

*1 if X*

*.*

*0*

*The method python is programmed as follows:*

*def HEAVYSIDE (X):*

*yew x<0. : return 0.*

*Yew x>=0. : return 1.*

*F\_HVS = FORMULA (NOM\_PARA = "INST",*

*VALE = "HEAVYSIDE (INST)")*

***Caution:***

*The use of programming PYTHON in the command file (here method HEAVYSIDE) is incompatible with the edition of this file with EFICAS.*

***VALE***

***VALE = v***

***Value of the constant (a real number).***

***3.3 Operand***

***TITRATE***

***TITRATE = Ti***

***Titrate attached to the concept produced by this operator [U4.03.01].***

***4 Examples***

```
Young = DEFI_PARA_SENSI (  
VALE = 2.1E11  
)
```

*The Young size is a constant being worth 2.1E11. One then uses it in the definition of one material:*

```
naked = DEFI_CONSTANTE (VALE = 0.3)  
chechmate = DEFI_MATERIAU (ELAS_FO = _F (E = Young, NAKED = naked  
))
```

*One will calculate the field of displacement and his derivative compared to this Young modulus:*

```
resu = MECA_STATIQUE (...  
SENSITIVITY  
=  
(Young),  
...  
)
```

## **3 Operands**

### **3.1 Operand**

**NAME**

***This key word factor makes it possible to file the characteristics of the derivation of a structure: under which***

***name is known the derived structure, which are the key words which engage derivation.***

#### **3.1.1 Operand**

**NOM\_SD**

***NOM\_SD = nom\_sd***

***It is the name of the structure to be derived. Attention, this name is to be provided in the form of a chain of***

***characters and not in the form of concept. Indeed at the moment when procedure***

***MEMO\_NOM\_SENSI is called upon, the concept to be derived does not exist obligatorily. It can be product later and is thus unknown analyzer of order.***

#### **3.1.2 Operand**

**PARA\_SENSI**

***PARA\_SENSI = para\_sensi/theta\_geom***

***It is the concept of the para\_sensi type or theta\_geom by report/ratio to which one derives.***

#### **3.1.3 Operand**

**NOM\_COMPOSE**

***NOM\_COMPOSE = nom\_compose***

*One gives here the name of the concept resulting from derivation of nom\_sd compared to para\_sensi. Here still, it is a character string because the concept is not obligatorily known.*

***3.1.4 Operand  
MOT\_CLE***

***MOT\_CLE = l\_mot\_simp***

*The derivation of nom\_sd compared to para\_sensi is carried out by an order which can be a definition of material, a loading, a resolution,... When in this order, that is done through key words, one gives the list of it here.*

***3.1.5 Operand  
VALUE***

***VALUE = l\_val***

*If key words were indicated by operand MOT\_CLE, the list of the values here is given corresponding in the form of character string. The two lists l\_mot\_simp and l\_val function in parallel.*

***3.1.6 Operand  
MOT\_FACT***

***MOT\_FACT = l\_mot\_fact***

*If key words were indicated by operand MOT\_CLE, one gives the list here of key words corresponding factors. The two lists l\_mot\_simp and l\_mot\_fact function in parallels.*

***3.2 Operand  
NOM\_ZERO***

***NOM\_ZERO = f0***

*One gives here the concept of an always null function.*

*Instruction manual*

*U4.31.07-B Page*

*: 4/4*

### ***3.3 Operand***

***NOM\_UN***

*NOM\_UN = f1*

*One gives here the concept of a function always being worth 1.*

### ***4 Examples***

***A priori, this procedure should never be employed directly by an end-user. It is activated by the automatic mechanism of piloting of the sensitivities.***

#### ***4.1 Function***

***unit***

***One defines F1 as function always being worth 1 and one memorizes it.***

***F1 = DEFI\_CONSTANTE (VALE = 1.) ;***

***MEMO\_NOM\_SENSI (NOM\_UN = F1);***

#### ***4.2 Structures***

***derived***

***A material is defined thanks to a significant parameter. It is necessary to memorize its derived material and how it is obtained.***

***PS = DEFI\_PARA\_SENSI (VALE = 40.)***

***CHECHMATE = DEFI\_MATERIAU (THER\_FO = \_F (LAMBDA = PS));***

***MEMO\_NOM\_SENSI (NAME = \_F (NOM\_SD = "CHECHMATE",***

***PARA\_SENSI***

=

***PS,***

***NOM\_COMPOSE***

=

***“MAT\_PS”,***

***MOT\_CLE***

## ***Operator CALC\_FONC\_INTERP***

### ***1 Goal***

***To build a concept of the function type starting from a function FORMULATES to 1 or 2 variables.  
Can  
to be defined real functions with real and complex variables and tablecloths.***

***One can also produce a new real or complex function, or a tablecloth while interpolating  
another real, complex function or a tablecloth.***

***The use of CALC\_FONC\_INTERP allows a preliminary tabulation of the formula. Its use is  
recommended before any transitory and/or nonlinear analysis for reasons of performances.  
The operator is not any more réentrant: he takes a formula in argument and produces a function or  
one  
tablecloth.***

### **3 Operands**

#### **3.1 Operand**

**FUNCTION**

**FUNCTION = F**

*Name of the FORMULA (interpretable function (FORMULA cf [U4.31.05])).*

*This function can be with one or two variables.*

*One can however create a new function (respectively fonction\_c, tablecloth) to leave of a function (respectively fonction\_c, tablecloth) by interpolating the first on a list parameters different. This probability is primarily used in macro-orders.*

#### **3.2 Operand**

**NOM\_RESU**

**NOM\_RESU = NR**

*Indicate the name of the result, the function thus created is a function whose value is of name NR (8 characters).*

#### **3.3 Operand**

**NOM\_PARA**

***NOM\_PARA = NR***

***Indicate the name of the parameter of the function or tablecloth. By defect, the name of the parameter formula or provided function is employed.***

### ***3.4 Operands***

***VALE\_PARA/LIST\_PARA***

***/VALE\_PARA = lvale,***

***lvale is the list of the values of the parameter.***

***/LIST\_PARA = will lpara,***

***will lpara is the list of the values of the parameter: it is a concept of the listr8 type created previously by order DEF1\_LIST\_REEL [U4.34.01].***

### ***3.5 Operands***

***PROL\_DROITE and PROL\_GAUCHE***

***PROL\_DROITE and PROL\_GAUCHE =***

***Define the type of prolongation on the right (on the left) of the field of definition of parameter of the function or the tablecloth***

***“CONSTANT”***

***for a prolongation with the last (or first) value of function,***

***“LINEAR”***

***for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),***

***“EXCLUDED”***

***the extrapolation of the values apart from the field of definition of parameter is prohibited (in this case if a calculation requires a value function out of the field of definition, the code will stop in fatal error),***

**U4.32.01-F Page**

**: 4/6**

### **3.6 Operand**

#### **Interpol**

#### **Interpol**

=

*Type of interpolation of the function enters the values of the variable or type of interpolation of tablecloth enters the values of the parameter. Behind this key word one awaits a parameter list (two to the maximum).*

*“FLAX”: linear,*

*“LOG”: logarithmic curve,*

*“NOT”: one does not interpolate (and thus the program will stop if for the value is asked function for a value of the parameter where it was not defined).*

*If only one value is given, the interpolation will be identical for the X-coordinates and them ordinates. If two values are given, the first corresponds to the interpolation of X-coordinates and the second with the interpolation of the ordinates.*

### **3.7 Operand**

#### **NOM\_PARA\_FONC**

**NOM\_PARA\_FONC = NR**

*Indicate the name of the variable of the functions defining the tablecloth.*

### **3.8 Operands**

## ***VALE\_PARA\_FONC/LIST\_PARA\_FONC***

***/VALE\_PARA\_FONC = lvale,***

***lvale is the list of the values of the variable of the functions defining the tablecloth.***

***/LIST\_PARA\_FONC = will lpara,***

***will lpara is the list of the values of the variable of the functions defining the tablecloth: it is one concept of the listr8 type created previously by order DEFI\_LIST\_REEL [U4.34.01].***

### ***3.9 Operands***

***PROL\_DROITE\_FONC and PROL\_GAUCHE\_FONC***

***PROL\_DROITE\_FONC and PROL\_GAUCHE\_FONC =***

***Define the type of prolongation on the right (on the left) of the field of definition of variable of the functions of the tablecloth:***

***“CONSTANT”, “LINEAR”, “EXCLUDED” the same direction has as previously.***

### ***3.10 Operand***

***INTERPOL\_FONC***

***INTERPOL\_FONC***

***=***

***Defining type of interpolation of the functions between the values of the variable of the functions tablecloth. Behind this key word one awaits a parameter list (two to the maximum).***

***Operation is identical to Interpol.***

### ***3.11 Operand***

***INFORMATION***

***INFORMATION***

***=***

***Specify the options of impression on the file MESSAGE.***

**1: no the impression (default option)**

**2: impression of the parameters plus the list of the first 10 values in the order crescent of the parameter**

### **3.12 Operand**

**TITRATE**

**TITRATE = Ti**

**Titrate attached to the concept produced by this operator [U4.03.01].**

**Version**

**7.4**

**Titrate:**

**Operator** *LIRE\_FONCTION*

**Date:**

**19/01/05**

**Author (S):**

**C. Key DURAND**

**:**

**U4.32.02-G Page**

**: 3/6**

**3 Operands**

**3.1 Operand**

**UNIT**

**UNIT = U**

**Entirety, logical number of the unit of reading.**

**3.2 Operand**

**FORMAT**

**FORMAT = "FREE",**

**This key word is for the moment useless. It will be able to make it possible in the future to define a format of reading**

**specific, more constraining than the current format.**

**3.3 Operands** *PROL\_DROITE/PROL\_GAUCHE/NOM\_PARA/*

*NOM\_RESU/INTERPOL/VERIF/TITLE/INFORMATION*

***LIRE\_FONCTION* is an macro-order: the numerical values are read in the file indicated by PYTHON then the function is actually created by *DEFI\_FONCTION* [U4.03.01].**

**Thus, these key words are taken again with identical *DEFI\_FONCTION* and make it possible to specify them**

**characteristics of the produced function: interpolation, prolongations, names of the parameters of**

**access.**

### **3.4 Operand SEPAR**

**SEPAR**  
=/"None"/" , "/" ; " /" /"

*Separating character of the columns of figures in the file with reading.  
The default value "None" means one or more white characters. For the others  
separators, of the white characters can also fit between the figures and the separator  
itself.*

### **3.5 Operand INDIC\_PARA**

**INDIC\_PARA** =  
/[indice1, indice2]

*This key word is identical in its principle to other key words INDIC\_\* of the order. It  
allows to choose the column of figures in the file read which will define the X-coordinates of the  
function,  
are the values of the parameter.*

*One awaits obligatorily a list of two entreties: the first indicating the number of "block"  
in the file (cf paragraph [§4] Examples), the second indicating the number of the column. For  
to identify the blocks of the file, one regards as separator of blocks any line which  
would not exclusively contain figures and separators of columns. The columns are  
defined by the presence of separators of columns delimiting them (key word SEPAR).*

*The default value is [1,1]: the first column of the first block is read. That makes it possible to define  
very easily, by informing less possible key words, the reading of a function in one  
file containing two simple columns of figures.*

### **3.6 Operand TYPE**

**TYPE**

=

/

"FUNCTION"

,  
[DEFECT]

/"FONCTION\_C"

,"TABLECLOTH"

Specify the type of function read and created: "FUNCTION", "FONCTION\_C" (call in macro-order with *DEFI\_FONCTION*) or "TABLECLOTH" (call to *DEFI\_NAPPE*).

*Instruction manual*

*U4.3- booklet: Function*

*Author (S):*

**C. Key DURAND**

:

*U4.32.02-G Page*

: 4/6

**3.7**

***Case of a real function: TYPE=' FONCTION'***

*INDIC\_RESU =*  
*/[indice1, indice2]*

*Of operation identical to INDIC\_PARA, this key word allows to choose the column of figure in the file read defining the ordinates of the function, are the values of the result.*

*The default value is [1,2]: the second column of the first block is read.*

### **3.8**

***Case of a complex function: TYPE=' FONCTION\_C'***

*FORMAT\_C =*  
*“REEL\_IMAG”*  
*INDIC\_REEL =*  
*/[indice1, indice2]*  
*INDIC\_IMAG =*  
*/[indice1, indice2]*

*FORMAT\_C =*  
*“MODULE\_PHASE”*  
*INDIC\_MODU =*  
*/[indice1, indice2]*  
*INDIC\_PHAS =*  
*/[indice1, indice2]*

*In the case of a complex function, two columns of figures (actual values) are to be identified in the file read to define the list of the complex values of the result. One can thus read with the choice real/left part imaginary or modulates/phase.*

*The default values are respectively [1,2] and [1,3]: one reads the second and third columns first block. The first column read by defect having been the value of the parameter (INDIC\_PARA).*

### **3.9**

***Case of a tablecloth: TYPE=' NAPPE'***

*NOM\_PARA\_FONC*  
*= cf key word NOM\_PARA*  
*INDIC\_ABSCISSE =*  
*[indice1, indice2],*

*INTERPOL\_FONC*

= cf key word *ITERPOL*

*PROL\_DROITE\_FONC* = cf key word *PROL\_DROITE*

*PROL\_GAUCHE\_FONC* = cf key word *PROL\_GAUCHE*

*DEFI\_FONCTION*

=

*\_F* (

*INDIC\_RESU*

=

[*indice1*, *indice2*],))

*The principle is the same one as that of DEFI\_NAPPE [U4.31.03]: the list of possible values of parameter (second variable) having been defined by INDIC\_PARA, it remains to identify the functions in the file read by the key word factor DEFI\_FONCTION (similar to the key word factor FUNCTION DEFI\_NAPPE). Attention, the number of identified functions (occurrences of the key word factor) will have to be identical to the cardinal of the values read by INDIC\_PARA.*

*Contrary to the tablecloths in general, one imposes that the functions divide the same list of values of X-coordinates INDIC\_ABSCISSE, this is why only INDIC\_RESU is present under the word key factor DEFI\_FONCTION.*

## **4 Examples of use**

*That is to say the textual file following containing information to reading. It is composed of columns of figures, here separated by white characters, defining blocks, themselves delimited by free text.*

*Any line understanding of other characters that figures and the preset separator is considered like free text delimiting.*

```

aaa bbb ccc
ddd
eee fff
0. 0. 0.
0.1 1. 10.
0.2 2. 20.
0.3 3. 30.
xxx yyy
www zzz
0.4 4. 40. 400.
0.5 5. 50. 500.
0.6 6. 60. 600.
xxx
70. 700.
80. 800.
90. 900.
PPP qqg
8.8
9.9

```

*Or, with a separator:*

```

...
0.1 ; 1. ; 10. ; 100.
0.2 ; 2. ; 20. ; 200.
...

```

### **4.1 Reading of a simple function**

*By exploiting the default values for the choice of the columns:*

*F=LIRE\_FONCTION (UNIT = 38,*

*NOM\_PARA = "INST",)*

*The function thus created is:*

*X-coordinates =*

*[0., 0.1, 0.2, 0.3]*

*Ordinates = [0. , 1. , 2. , 3. ]*

*While associating for X-coordinates and ordinates of the columns taken in different blocks:*

*F=LIRE\_FONCTION (UNIT = 38,*

*NOM\_PARA = "INST",*

*INDIC\_PARA = [2,4],*

*INDIC\_RESU = [3,1],*

*The function thus created is:*

*X-coordinates =*

*[400., 500., 600.]*

*Ordinates = [70. , 80. , 90.]*

*Attention, the order checks whereas the cardinals of the columns defined by INDIC\_PARA and INDIC\_RESU are quite identical. What would not have been the case here with for example*

*INDIC\_PARA =*

*[1,4].*

## ***Reading of a complex function***

*By exploiting the default values for the choice of the columns:*

```
F=LIRE_FONCTION (UNIT
= 38,
NOM_PARA =
“INST”,
TYPE =
“FONCTION_C”,
FORMAT_C = “REEL_IMAG”,)
```

*The function thus created is:*

```
X-coordinates =
[0., 0.1, 0.2, 0.3]
Ordinates = [(0. , 0.) , (1. , 10.) , (2. , 20.) , (3. , 30.)]
```

*One could of course have specified other columns for INDIC\_REEL and INDIC\_IMAG that those by defect. Attention however to point on columns in the same way cardinal.*

### **4.3**

#### ***Reading of a tablecloth***

*By exploiting the default values for the choice of the columns:*

```
F=LIRE_FONCTION (UNIT
=
38,
NOM_PARA
=
“INST”,
INDIC_PARA =
[4,1],
NOM_PARA_FONC
=
“FREQ”,
INDIC_ABSCISSE =
[2,2],
DEFI_FONCTION
=
(
F (INDIC_RESU = [3,1],),
F (INDIC_RESU = [2,3],),))
```

*The tablecloth thus created is:*

*For the value of parameter INST=8.8, the function:*

*X-coordinates =*

*[4. , 5. , 6.]*

*Ordinates = [70. , 80. , 90.]*

*For the value of parameter INST=9.9, the function:*

*X-coordinates =*

*[4. , 5. , 6.]*

*Ordinates = [40. , 50. , 60.]*

*The checks of coherence of the cardinals of columns of X-coordinates and ordinates are made by the macro-order.*

***1 Goal***

*To extract in the form of a function the evolution from a size according to an other.*

*If the extraction is carried out starting from a structure of data result, or a field of size `cham_gd`, or of a `resu_gene`, the produced function corresponds to the temporal evolution of one component in a node or a point of Gauss of the grid.*

*Of a structure of data `tran_gene`, one can also extract the evolution from two parameters in a node of shock.*

*From a table, one can extract the evolution from 2 parameters in the columns of the table or a function contained in a box of the table.*

*From a structure of data `melasflu` one can extract, the evolution of modal parameters in function rate of flow of the fluid.*

*Product a structure of data of the function type.*

*At exit of the order, the function is reordered by increasing X-coordinates.*

### **3 Operands**

#### **3.1 Operand**

**RESULT**

*/RESULT = resu*

*Name of the concept of the result type to which the extraction relates.*

*For the operands allowing to extract the field, to refer to [§3.7].*

*For the operands allowing to locate the field, to refer to [§3.8].*

#### **3.2 Operand**

**CHAM\_GD**

*/CHAM\_GD = ch\_gd*

*Name of the concept of the cham\_gd type produces by RECU\_CHAMP [U4.71.01] or CALC\_CHAM\_ELEM [U4.81.03] on which carries the extraction.*

*For the operands allowing to locate the field, to refer to [§3.7].*

#### **3.3 Operand**

**RESU\_GENE**

##### **3.3.1 Temporal evolution of a physical, standard component tran\_gene**

**RESU\_GENE = embarrassment**

*Name of the concept of the `resu_gene` type produces by `DYNA_TRAN_MODAL` [U4.53.21] on which carry the extraction.*

*The recovered function is expressed with the physical variables and not with the variables generalized.*

### **3.3.1.1 Operands**

**`MULT_APPUI` and `ACCE_MONO_APPUI`**

**`MULT_APPUI`**

*If this key word is “YES”, one restores the evolution of the variables in physical space in dealing with the problem moving absolute in the case of an excitation multi-support. In contrary case, the restitution in physical space is done by supposing that the problem is treaty moving relative. This key word is not usable if key word `CORR_STAT` is used.*

**`ACCE_MONO_APPUI`**

*In the case of an acceleration mono-support, one must indicate here the acceleration imposed on all supports in the direction considered in order to calculate the absolute acceleration of the point. If the key word is not indicated, one obtains relative acceleration in result of order.*

**Note:**

*The name of the concept must be same as that well informed under `FONC_MULT` of `DYNA_TRAN_MODAL`.*

### **3.3.1.2 Operands**

**`CORR_STAT`**

**`CORR_STAT`**

*If this key word is “YES”, the evolution of the variables in physical space is obtained in taking account of the correction due to the catch in consideration of static modes (Cf [R4.05.03]). This key word is not usable if key word `MULT_APPUI` is used.*

### **3.3.1.3 Information concerning the nodes of shock**

**/**

**RESU\_GENE = embarrassment**

**Concept of the tran\_gene type containing for the various nodes of shock**

**:**

**local displacements, normal and tangential speeds and normal forces of shock and tangential.**

**/**

**NOEUD\_CHOC = nd\_choc,**

**GROUP\_NO\_CHOC**

**=**

**no\_choc,**

**Name of the node or the group of nodes (which contains one node) shock where one recover the function.**

**This node of shock is defined in order DYNA\_TRAN\_MODAL [U4.53.21].**

**PARA\_X = nparax**

**Name of the parameter defining the X-coordinates (argument taken among the list: "INST", "FN", "FT1", "FT2", "DXLOC", "DYLOC", "DZLOC", "VN", "VT1", "VT2").**

**PARA\_Y = nparay**

*Name of the parameter defining the ordinates (argument taken among the list: “INST”, “FN”, “FT1”, “FT2”, “DXLOC”, “DYLOC”, “DZLOC”, “VN”, “VT1”, “VT2”).*

*LIST\_PARA = will li\_para*

*List values of the parameter in X-coordinate defining the function.*

*ENTITLE = name*

*This name defines the connection of shock (this name if it is used, is defined in the order DYNA\_TRAN\_MODAL [U4.53.21]).*

*SOUS\_STRUC = nom\_str*

*During a calculation in dynamic under-structuring, name of the substructure which contains it node of shock (cf orders DEFI\_MODELE\_GENE [U4.65.02]). In this case the key word ENTITLE must be also well informed.*

*3.3.2 Frequential evolution of a generalized or physical, standard component  
harm\_gene/mode\_gene*

*RESU\_GENE = embarrassment*

*Name of the concept of the harm\_gene type produces by DYNA\_LINE\_HARM [U4.53.11] or mode\_gene produces by MODE\_ITER\_SIMULT [U4.53.03] or MODE\_ITER\_INV [U4.53.04].*

*The recovered function is expressed with the physical variables if NOM\_CMP is present, with the generalized variables if NUME\_CMP\_GENE is present.*

*NOM\_PARA\_RESU/NOM\_CHAMP*

[See paragraph 3.7.](#)

*NOM\_CMP/NODE/GROUP\_NO*

[See paragraph 3.8.](#)

## ***SKELETON***

***COUNT***

***One can recover:***

- is a function defined starting from two columns of the table,***
- is a function whose name is indicated in a box of the table.***

***/TABLE = tabl***

***Name of the table result in which one carries out an extraction.***

### ***3.4.1 Function defined starting from two columns of the table***

#### ***3.4.1.1 Operands***

***PARA\_X/PARA\_Y***

***PARA\_X = nparax***

*Name of the column of the table defining the X-coordinates.*

***PARA\_Y = nparay***

*Name of the column of the table defining the ordinates.*

### ***3.4.2 Function whose name is indicated in a box of the table***

#### ***3.4.2.1 Operand***

***NOM\_PARA\_TABL***

***NOM\_PARA\_TABL= "FUNCTION"***

*The presence of this key word indicates that one recovers the function whose name is registered in a box of the table.*

#### ***3.4.2.2 Operand***

***TYPE\_RESU***

***TYPE\_RESU =***

*Type of the function to be recovered: function with actual value ("FUNCTION") or with values complexes ("FONCTION\_C").*

### ***3.4.3 Word***

***key***

***FILTER***

*The operands of extraction are different from those used for the preceding cases. To realize the extraction, it is necessary to use the key word FILTERS and operands NOM\_PARA, CRIT\_COMP, VALE\_X, CRITERION, PRECISION.*

*This key word factor makes it possible to filter the information stored in the table. For the use of it key word to see order IMPR\_TABLE [U4.91.03].*

*To recover a function whose name is indicated in a box of the table, It is necessary to use at least twice the key word factor FILTERS to select only the useful box.*

### **3.5 Operand**

#### **BASE\_ELAS\_FLUI**

*One recovers in a structure of data of the melasflu type produced by the operator CALC\_FLUI\_STRU [U4.66.02], evolutions of the frequency or damping, for a mode given, according to various speeds of excitation of the fluid.*

/  
**BASE\_ELAS\_FLUI = flui**

*Concept of the melasflu type produces by order CALC\_FLUI\_STRU.*

#### **3.5.1 Operands**

##### **NUME\_ORDRE/TOUT\_ORDRE**

/NUME\_ORDRE = is,  
/  
**TOUT\_ORDRE**  
=  
"YES",

*The evolution of the frequency or that of damping is given for all speeds fluid (TOUT\_ORDRE) or for some sequence numbers speeds of the fluid (NUME\_ORDRE).*

*Instruction manual*

*U4.3- booklet: Function*

*HT-62/06/004/A*

**Author (S):**

**Key COURTEOUS Mr.**

**:**

**U4.32.03-H1 Page:**

**8/14**

### **3.5.2 Operand** **NUME\_MODE**

*/NUME\_MODE = im*

*Number of the mode for which the extraction of the frequency or damping in function speed of the fluid is carried out.*

### **3.5.3 Operands** **PARA\_X/PARA\_Y**

*PARA\_X = "VITE\_FLU"*

*In X-coordinate, the parameter is the speed of excitation of the fluid, of name "VITE\_FLU".*

*PARA\_Y =  
/"FREQ",  
/  
"AMOR",*

*In ordinate, there are the choice between the frequency (name of the parameter: "FREQ") or damping (name of parameter "AMOR").*

### **3.6 Operand** **OBSTACLE**

*One recovers in a structure of data of the obstacle type a function describing the profile of one obstacle in co-ordinates polar or Cartesian.*

*A function having by nature of the monotonous X-coordinates, it is more judicious to recover this profile  
in a table.*

*The key word REFERENCE MARK makes it possible to choose in which frame of reference one recovers the profile.*

### **3.7** **Operands of extraction of the field or the parameter**

#### **3.7.1 Operand** **NOM\_CHAM**

/  
***NOM\_CHAM = nomsymb***

***Reference symbol of the field to which the extraction relates.***

***3.7.2 Operand***  
***NOM\_PARA\_RESU***

/  
***NOM\_PARA\_RESU = parameter***

***Reference symbol of the structural parameter of data which one wants to extract (by example: ETA\_PILOTAGE, MASSE\_EFFE\_DX, MASSE\_GENE...).***  
***See booklets [U5] Structures of data RESULT.***

***The extracted function will then have as a X-coordinate the variable of access (INST, FREQ...) and for ordinate the value of parameter.***

***3.7.3 Operands***  
***TOUT\_ORDRE/NUME\_ORDRE/TOUT\_INST/LIST\_ORDRE***

***/TOUT\_ORDRE = "YES"***  
***(default value)***

***This key word indicates that one wants to extract for all the already calculated sequence numbers.***

***Example: every moment for a result of the evol\_\* type.***

/  
***NUME\_ORDRE = l\_num***

***The extraction will be done for the values of sequence number l\_num provided.***

/  
***TOUT\_INST = "YES"***

***This key word indicates that one wants to extract for every moment.***

**LIST\_ORDRE = l\_ord**

*This key word indicates that one wants to extract with the sequence numbers described in the concept l\_ord of the listis type.*

**3.7.4 Operands**

**INST/LIST\_INST/FREQ/LIST\_FREQ**

**/**  
**INST = l\_inst**

*This key word indicates that one wants to extract at the moments l\_inst.*

**/**  
**LIST\_INST = li\_inst**

*This key word indicates that one wants to extract at the moments described in the concept li\_inst of listr8 type.*

/  
**FREQ = l\_freq**

*This key word indicates that one wants to extract at the frequencies l\_freq.*

/  
**LIST\_FREQ = li\_freq**

*This key word indicates that one wants to extract at the frequencies described in the concept li\_freq of listr8 type.*

### **3.7.5 Operands**

#### **PRECISION/CRITERION**

**PRECISION = prec**

*This operand makes it possible to indicate that one seeks the value of the field of which the moment or frequency is in an interval defined by the absolute or relative position:  
“inst ± prec” (cf CRITERION).*

*By defect prec = 1.0D-3*

**CRITERION =**

*“RELATIVE” the interval of research is  
[inst (1-prec), inst (1+prec)]*

*“ABSOLUTE” the interval of research is  
[inst-prec, inst+prec]*

### **3.7.6 Operand**

#### **INTERP\_NUME**

*This key word defines the type of interpolation between two sequence numbers. It is valid only in case where the user defined a list of moments or frequencies. It is possible to prohibit the interpolation “NOT” or to admit a linear interpolation “FLAX”.*

*The interpolation cannot be used when one extracts the value from a parameter (key word NOM\_PARA\_RESU).*

## **3.8**

## ***Operands of localization of the field***

### ***3.8.1 Operands***

***NODE/GROUP\_NO***

***/NODE = No***

***Name of the node to which the extraction relates.***

***/***

***GROUP\_NO***

***=***

***grno***

***Name of the group of nodes, containing 1 only node, to which the extraction relates.***

***Instruction manual***

***10/14***

### ***3.8.2 Operands***

***NET/GROUP\_MA/NODE/GROUP\_NO/NOT***

***/MESH = my***

***/GROUP\_MA = grma***

*Name of the mesh (my) or name of a group of meshes (grma), containing only one net, to which the extraction relates. These key words relate to only the cham\_elem.*

**/NODE = No**

*Name of a node of the mesh to which the extraction (case of the cham\_elem relates with the nodes).*

**/  
GROUP\_NO**

**=  
grno**

*Indicate the name of the group of nodes, container only one name of node, on which carries the extraction (case of the cham\_elem to the nodes).*

**/  
NOT**

**=  
nupoint**

*The entirety nupoint specifies the local number with the element of the point of GAUSS which one wishes to obtain the value (case of the cham\_elem at the points of GAUSS).*

**SOUS\_POINT = nusp**

*The entirety nusp specifies the number of the under-point of which one wishes to obtain value (case of the cham\_elem at under-points, used by the elements of structure: beam, pipes, hulls).*

*The number of under-point is the number of the layer in an element of hull, the number of fibre in an element of beam multifibre or them elements pipes. The classification of the layers or fibres is described in documentation of the elements using the concept of under-point (cf [R3.07.03], [R3.07.04], [R3.08.06] and [R3.08.08]).*

**3.8.3 Operand  
NOM\_CMP**

***NOM\_CMP = cmp***

***Name of the component of the size to which the extraction relates.***

### ***3.9***

***Attributes of the concept function created by RECU\_FONCTION***

#### ***3.9.1 Default values***

***By defect the attributes of the concept function created by order RECU\_FONCTION are:***

***Interpolation: "NOT"***

***Left prolongation: "EXCLUDED"***

***Right prolongation: "EXCLUDED"***

***NOM\_PARA: given in entry***

***NOM\_RESU: given in entry***

#### ***3.9.2 Overload attributes***

***The user can overload the attributes given by defect by using the key words following:***

Titrate:

Operator *RECU\_FONCTION*

Date:

22/02/06

Author (S):

Key **COURTEOUS Mr.**

:

*U4.32.03-H1 Page:*

11/14

### **3.9.2.1 Operand**

***NOM\_PARA***

*NOM\_PARA = para*

*He indicates the name of the parameter (variable or X-coordinate) of the function. Values currently authorized for will lpara are:*

/

**“TEMP”**

/

**“INST”**

/

**“EPSI”**

/

**“X”**

/

**“Y”**

/

**“Z”**

/

**“FREQ”**

/

/

“DY”

/

“DZ”

/

“DRX”

/

“DRY”

/

“DRZ”

*more those specific to the nodes of shock (cf [§ 3.3.2.2]).*

### **3.9.2.2 Operand**

#### ***NOM\_RESU***

*NOM\_RESU = resu*

*It indicates the name of the result, the function thus created is a function whose value is of name lresu (8 characters).*

### **3.9.2.3 Operand**

#### ***Interpol***

*Interpol*

*Type of interpolation of the function enters the values of the parameter of the field of definition. Behind this key word one awaits a parameter list (two to the maximum) among “NOT”, “FLAX”, “LOG”. If only one value is given the interpolation will be identical for X-coordinates and ordinates. If two values are given, the first corresponds to the interpolation of the X-coordinates and the second with the interpolation of the ordinates.*

### **3.9.2.4 Operands**

#### ***PROL\_DROITE/PROL\_GAUCHE***

*PROL\_DROITE and PROL\_GAUCHE*

*They define the type of prolongation on the right (on the left) of the field of definition of variable:*

.

*“CONSTANT” for a prolongation with the last (or first) value of function,*

*“LINEAR” for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),*

*“EXCLUDED” if extrapolation from the values apart from the field of definition from parameter is prohibited.*

### **3.10 Operand TITRATE**

*TITRATE*

*Titrate attached to the concept produced by this operator [U4.03.01].*

### **3.11 Operand INFORMATION**

*INFORMATION*

*Specify the options of impression on the file MESSAGE.*

*1  
no impression (by defect)*

*2  
impression of the descriptor of the function and the list of the first 10 values of function in the order ascending of the first 10 parameters*

***1 Goal***

***To carry out mathematical operations on structures of data of the function type.***

***The following operations are currently available:***

.

***the derivation of a function,***

.

***the integration of a function,***

.

***the reverse of a function,***

.

*the absolute value of a function,*

.

*the research of the envelope of several functions,*

.

*real or complex linear combination several functions,*

.

*the composition of two functions,*

.

*concatenation (put end to end with management of the overlappings) several functions,*

.

*the extraction of a real function starting from a complex function,*

.

*the calculation of the nth power of a function,*

.

*the calculation of direct or opposite FFT of a function,*

.

*correction of a accélérogramme measured for calculation of a seismic answer,*

.

*smoothing wraps one or more rough spectra of oscillator,*

.

*the calculation of the spectrum of oscillator of a accélérogramme (function of the frequency and of damping) in the form of a tablecloth,*

*Product a structure of data function, or tablecloth, according to the key word factor used.*

*At exit of the order, the function is reordered by increasing X-coordinates.*

### **3 Operands**

#### **3.1 Word**

*key*

**DERIVES**

**/DRIFT**

=

*The function F (T) is derived.*

**FUNCTION = F**

*Name of the function which one wishes to derive.*

*Do not apply to the concepts of the tablecloth type.*

**METHOD =**

*Name of the METHOD which one wishes to use: the only method available is currently  
DIFF\_CENTREE (by defect).*

*Note:*

*See JUST key word.*

#### **3.2 Word**

**key**  
**JUST**

**/JUST**  
**=**

**The function  $F(T)$  is integrated.**

**FUNCTION = F**

**Name of the function which one wishes to integrate.  
Do not apply to the concepts of the tablecloth type.**

**METHOD =**

**Name of the METHOD which one wishes to use.**

**Two methods are available: method of the "TRAPEZOID" (by defect) and method of "SIMPSON".**

**The method of "SIMPSON" is to be employed with precaution because it can involve oscillations. It is to better discretize  $F(T)$  finely and to integrate with the method of "TRAPEZOID". In particular it is disadvised using method "SIMPSON" for the interpretation of a accélérogramme.**

**COEF = R**

**Constant of integration, by defect 0.**

**Note:**

- For JUST as for DRIFT, the NOM\_PARA of the produced function is unchanged: one does not have for example to expect only NOM\_RESU=' ACCE' NOM\_RESU=' VITE' in the integrated function produces. The user with the faculty of to modify by the key word of the same name in CALC\_FONCTION.**
- Concerning the prolongations, the produced function has by defect of the prolongations EXCLUDED on the left and on the right, some are those of the starting function. Not to thus expect that a linear prolongation becomes constant in the function derived... There still, the user is a Master of his prolongations for the function produced by key words PROL\_DROITE and PROL\_GAUCHE.**

**: 8/20**

### **3.3 Word**

*key*

**OPPOSITE**

**/OPPOSITE**

**=**

*The function  $F(T)$  is reversed.*

**FUNCTION = F**

*Name of the function which one wishes to reverse, it is necessary that this one is bijective (strictly increasing or strictly decreasing).*

*Do not apply to the concepts of the tablecloth type.*

**Note:**

- The labels of the parameters are not reversed! The care is left with the user to affect the correct values by the key words **NOM\_PARA** and **NOM\_RESU**. Par defect, the **NOM\_PARA** is unchanged and **NOM\_RESU** is affected with “**TOUTRESU**”.*
- The modes of interpolations are inverted: e.g. (“**FLAX**”, “**LOG**”) becomes (“**LOG**”, “**FLAX**”).*
- The prolongations **EXCLUDED** and **LINEAR** are unchanged. On the other hand, one*

***CONSTANT*** prolongation is changed from of ***EXCLUDED***.

### ***3.4 Word***

***key***

***ABS***

***/ABS***

***=***

***Provides the absolute value of a function or a tablecloth.***

***FUNCTION = F***

***Name of the function which one wishes the absolute value.***

***Note:***

- Parameters (prolongations, interpolations, NOM\_PARA and NOM\_RESU) of produced function are the same ones as those of the starting function.***
- Except for the LINEAR prolongation: systematically changed from of EXCLUDED by precaution. Indeed, linear prolongation on the right of a decreasing function conduit for sufficiently large X-coordinates with negative values: responsibility is thus left with the user affect itself PROL\_DROITE=' LINEAIRE' (and respectively on the left).***

### ***3.5 Word***

***key***

***WRAP***

***/***

***WRAP***

***=***

***Calculation of the envelope of several functions.***

***This operation is available on operands of nature function or tablecloth.***

#### ***3.5.1 Operand***

***FUNCTION***

***FUNCTION = F***

***List functions or tablecloths which one seeks the envelope.***

***Instruction manual***

***U4.3- booklet: Function***

**HT-62/06/004/A**

---

**Author (S):**

**COURTEOUS Mr., D. THOMASSON, F. LEBOUVIER Key**

**:**

**U4.32.04-II Page**

**: 9/20**

**3.5.2 Operand**

**CRITERION**

**CRITERION =**

**/**

**“SUP”**

**The higher envelope is sought.**

**/**

**“INF”**

**The lower envelope is sought.**

**Remarks for the research of the envelope:**

**.**

**the functions all must be of comparable nature (function or tablecloth),**

**.**

**Case of the simple functions: for the prolongations, interpolations, NOM\_PARA and NOM\_RESU, they are the parameters of the first of the functions in the list which are retained. The support of X-coordinates of the function envelope will be the meeting of the lists X-coordinates of all the functions.**

**.**

**Case of the tablecloths: the parameters (prolongations, interpolations, NOM\_PARA, NOM\_RESU,**

***NOM\_PARA\_FONC)*** must imperatively be identical between the provided tablecloths. supports of X-coordinates (values of the parameters and X-coordinates of the functions of the tablecloths) are homogenized to be able to calculate the envelope. The produced tablecloth will have this discretization for X-coordinates.

### **3.6 Word**

**key**

**COMB and operand LIST\_PARA**

**/COMB =**

***Real linear combination several concepts of nature function or tablecloth.***

**FUNCTION = F**

***Name of the function to be combined.***

**COEF= R**

***Value of the coefficient.***

**LIST\_PARA= will lpara**

***List values of the parameters for which the combination of the functions will be discretized. If this key word is not indicated, a list by defect is built by taking the union of the lists of values of the parameters of each function.***

***Caution:***

***It is not a key word of the key word factor COMB.***

***Remarks for the combination:***

***See the remarks for the key word WRAPS***

### **3.7 Word**

**key**

**COMB\_C and operand LIST\_PARA**

**/COMB\_C**

**=**

*Linear combination complexes several concepts of nature fonction\_c.*

**FUNCTION =  
f\_c**

*Name of the function to be combined. It can be with complex or real values.*

**/COEF\_R = R,**

**/COEF\_C = C,**

*Value of the multiplying coefficient, either in real form R, or in form complexes C.*

**3.10 Word**  
**key**  
**EXTRACTION**

/  
**EXTRACTION**  
=

*Key word factor allowing to build starting from a complex function (standard fonct\_c), a real function representative either the real part, or the imaginary part, or the module, that is to say the phase of the complex function.*

**3.10.1 Operand FUNCTION**

**FUNCTION = f\_c**

*Complex function.*

**3.10.2 LEFT operand**

**PART**  
=

**/“REAL”**  
*: extraction of the real part of f\_c,*  
**/“IMAG”**  
*: extraction of the imaginary part of f\_c,*  
**/“MODULE”**: *extraction of the module of f\_c,*  
**/“PHASE”**: *extraction of the phase (in degree) of f\_c.*

**3.11 Word**  
**key**  
**POWER**

*This key word makes it possible to build the nth power of a function or a whole of functions provided in the form of a tablecloth.*

**FUNCTION = F**

*Name of the function F concerned (standard function or tablecloth).*

**EXHIBITOR = N**

*The function result calculated will be  $X F (X) N$ . By defect,  $N = 1$ .*

**3.12 Word**

**key**

**FFT**

**/FFT**

**=**

*One calculates the transform of Fourier direct or opposite of a function (algorithm FFT).*

**FUNCTION = F**

*Name of the function on which the operation is carried out.*

*If the NOM\_PARA of the function is INST, then the direct FFT is calculated.*

*If the NOM\_PARA of the function is FREQ, then the opposite FFT is calculated.*

*Do not apply to the concepts of the tablecloth type.*

**METHOD =**

*Algorithm FFT accepts in entry only one signal of which the number of samples is one power of 2.*

*Method "PROL\_ZERO" (by defect) proposes to prolong the input signal with zeros until having a total number of sample which is the first power of 2 whose value is higher than the initial number of samples.*

*The method "TRUNCATION" will consider only the first samples of which the total number is the greatest power of two whose value is lower than the initial number of sample.*

*For example, on a signal of 601 values, method "PROL\_ZERO" will supplement the signal for to have 1024 samples, whereas the method "TRUNCATION" will consider only them the first 512 moments.*

*If the input signal to a number of sample which is a power of two, two methods are obviously equivalent: one takes into account the signal without modifying it.*

**3.13 Word**

**key**

**CORR\_ACCE**

**/**

**CORR\_ACCE**

**=**

***Key word factor allowing to correct a accélérogramme measured for calculation of seismic response of a system.***

***One removes the drift of the signal, calculated by linear smoothing within the meaning of least squares***

***on the totality of the signal, in order to make the accélérogramme more realistic. Drift speed relative corresponding is also removed.***

***One turns over at exit the corrected accélérogramme.***

**3.13.1 Operand FUNCTION**

**FUNCTION = F**

***Measured real Accélérogramme.***

***Do not apply to the concepts of the tablecloth type.***

**3.13.2 Operand CORR\_DEPL**

**CORR\_DEPL**

**=**

**/**

**“NOT”**

***One does not correct the drift of relative displacement, it is the default value.***

**/**

**“YES”**

*One removes also the drift of relative displacement. This option is to be used with precaution, because one does not know a priori the value of final displacement after the seism.*

### **3.14 Word**

*key*

**LISS\_ENVELOP**

*The data of origin make up of a tablecloth of spectra SRO gross definite on large a number of points for a level of floor given.*

*The first stage consists, for each spectrum, with widening in frequency (shift on the left and) followed on the right by a reduction in the number of point of definition. These operations carried out, one*

*ensure yourself of the character wraps spectrum smoothed compared to the initial spectrum. This stage, each*

*spectrum has its own base of frequency.*

*The second stage consists in homogenizing the base of frequency of the whole of the spectra of tablecloth while ensuring itself of nonthe covering of the spectra between them.*

**TABLECLOTH = N**

*Name of the tablecloth of entry formed of the rough spectra associated each level of damping.*

**FREQ\_MIN and FREQ\_MAX**

*Beach of definition in frequency of the smoothed spectrum.*

*The frequencies mentioned under FREQ\_MIN and FREQ\_MAX must be selected among frequencies of discretization of the rough spectrum.*

*By defect, one considers the complete spectrum.*

**ELARG**

*Widening relates to the whole of the spectrum,*

*It is given expressed as a percentage and is worth 0.1 (10%) per defect.*

*For each  $F_i$  frequency of the rough spectrum, one defines two new values of frequencies such as:*

*.*  
 $F - = I$   
 $F (1 - G)$  with  $0 < G < 1$ ,  
*.*

**$F + = I$**   
 **$F (1 + D)$  with  $0 < D < 1$ .**

**“ABSC”**

### **3.16.2.2 Operand NOM\_RESU**

*NOM\_RESU = resu*

*It makes it possible to document, the function created by giving a name (8 characters) to the function. Except exception (cf [§3.1], [3.2], [§3.5]), this name is not tested.*

### **3.16.2.3 Operand Interpol**

*Interpol*

*Type of interpolation of the function enters the values of the parameter of the field of definition. Behind this key word one awaits a parameter list (two to the maximum) among “NOT”, “FLAX”, “LOG”. If only one value is given the interpolation will be identical for X-coordinates and ordinates. If two values are given, the first corresponds to the interpolation of the X-coordinates and the second with the interpolation of the ordinates.*

### **3.16.2.4 Operands PROL\_DROITE/PROL\_GAUCHE**

*PROL\_DROITE and PROL\_GAUCHE*

*They define the type of prolongation on the right (on the left) of the field of definition of variable:*

.

*“CONSTANT” for a prolongation with the last (or first) value of function,*

.

*“LINEAR” for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),*

.

*“EXCLUDED” if extrapolation from the values apart from the field of definition from parameter is prohibited.*

### **3.16.2.5 Operands NOM\_PARA\_FONC/INTERPOL\_FONC/PROL\_DROITE\_FONC/ PROL\_GAUCHE\_FONC**

*These key words make it possible to modify the attributes of the functions which intervene in the definition of tablecloths. They thus have the same significance as the key words without suffix FONC.*

### **3.17 Operand INFORMATION**

*INFORMATION*

=

*Specify the options of impression on the file MESSAGE.*

*1*

*no impression*

*2*

*impression of the descriptor of the function (default option) and of the list of the 10 first values of each function in the order ascending of the first 10 parameters.*

**5/10**

**3 Operands**

**3.1 Word**

**key**

**MAX**

**/MAX**

**=**

**Seek X-coordinates where the maximum and the minimum are reached.**

**This operation is available on functions of nature function or tablecloth.**

**FUNCTION = F**

**Name of the function of which one seeks the maxima.**

**If F is a function, the produced concept is a table whose parameters of access are:**

**FUNCTION, TYPE, the NOM\_PARA of the function, the NOM\_RESU of the function.**

**where one respectively finds the name of the function, MAXIMUM or MINI, the X-coordinate of the maximum/minimum,**

**the value of the minimum maximum/.**

**If F is a tablecloth, the produced concept is a table whose parameters of access are:**

**FUNCTION, TYPE, the NOM\_PARA of the tablecloth, the name of the parameter of the functions (NOM\_PARA\_FONC), the NOM\_RESU of the functions.**

### 3.2 Word

key

**NORMALIZES**

*This key word makes it possible to follow convergence in accordance with the L2 standard of a continuation of function F given*

**NR**

*in the form of a tablecloth. The table result comprises a line by function, the parameters of entry are STANDARD and FUNCTION.*

**FUNCTION = F**

*Name of the tablecloth whose standard must be evaluated.*

### 3.3 Word

key

**ECART\_TYPE**

**/ECART\_TYPE**

=

*One calculates the standard deviation of the function F (T) which is defined by:*

**1**

=

(

**2**

**tfin**

**T**

**F () - F)**

(

*where F is the average on [tdeb, tfin]*

**tfin - tdeb)**

**dt**

**tdeb**

*The key words are identical to those provided under the key word factor RMS.*

*The produced concept is a table whose parameters of access are:*

**FUNCTION, METHOD, AVERAGE, INST\_INIT, INST\_FIN, ECART\_TYPE.**

**3.4 Word**

**key**

**RMS**

**/RMS**

**=**

**One calculates value RMS of the function  $F(T)$  which is defined by:**

**1**

**$t_{fin}$**

**$RMS =$**

**2**

**(**

**$F$**

**$t_{fin} - t_{deb}$ )**

**$(T) dt$**

**$t_{deb}$**

**FUNCTION = F**

**Name of the function which one calculates value RMS.**

*Do not apply to the concepts of the tablecloth type.*

**METHOD =**

*Name of the METHOD which one uses to calculate the integral.*

*Two methods are available: method of the “TRAPEZOID” (by defect) and method of “SIMPSON”.*

**INST\_INIT = tdeb,**

**INST\_FIN = tfin,**

*Limits lower and higher of the interval of integration.*

*If these values are not indicated, the points of discretization inferior and superior (relation of order being defined compared to the parameter in X-coordinate) are taken as limits the interval of integration.*

**PRECISION =/0.001,**

**/**

**prec,**

**CRITERION =**

**/“ABSOLUTE”,**

**/**

**“RELATIVE”, [DEFECT]**

*One seeks a point of discretization of the function in an interval defined by the position absolute or relative around a value of the parameter of the X-coordinates for which the function must be estimated:*

**.**

**[inst (1-prec), inst (1+prec)] if CRITERION = “RELATIVE”**

**.**

**[inst - prec, inst + prec]**

**if CRITERION = “ABSOLUTE”**

*The produced concept is a table whose parameters of access are:*

*FUNCTION, METHOD, INST\_INIT, INST\_FIN, RMS.*

.  
 $\max \{v (T)\}$   
 $T [$   
 $T, \text{ it } F]$

According to the option, one must inform certain parameters, if one does not indicate an option, by defect, one thus calculate all the indices it is necessary all to inform.

The method of integration is the method of the “TRAPEZOID”

$INST\_INIT = tdeb,$   
 $INST\_FIN = tfin,$

Limits lower and higher of the interval of time.

If these values are not indicated, the points of discretization inferior and superior (relation of order being defined compared to the parameter in X-coordinate) are taken as limits the interval.

### ***3 Operands***

#### ***3.1***

##### ***Presentation of the curves***

***A whole of operands optional makes it possible to define the presentation of the curve. All have one default value.***

### **3.1.1 Operand FORMAT**

**FORMAT =**

*Format of impression of the function*

**“AGRAF”**

*impression intended for the software agraf, which also makes it possible to adapt them*

*parameters of presentation in interactive,*

**“TABLE”**

*the impression in columns makes it possible to import the data in one easily*

*spreadsheet, if several curves are given, it is the list of the X-coordinates of first function which is used to interpolate the values of the others functions,*

**“XMGRACE”**

*impression intended for the software xmgrace. One can also adapt them parameters of presentation in interactive. The use of the PILOT key word allows to directly produce a file image or postscript.*

### **3.1.2 Operand UNIT**

*UNIT = links*

*UNITE\_DIGR = unit\_digr if FORMAT = “AGRAF”*

*Allow to choose on which logical unit one prints the functions. The value of links must be the same one as in the interface askt.*

*If many curves are plotted, it is more flexible to use the repe type combined with order DEFI\_FICHER, the files will be in the ./REPE\_OUT repertory.*

*With format AGRAF, the data are written in UNIT whereas the directives are written in UNITE\_DIGR (is worth 26 per defect).*

*The default value of links is worth:*

- 8 with the format TABLE (corresponds to the file result),
- 25 with format AGRAF,
- 29 with format XMGRACE (optional if PILOT = “INTERACTIVE”)

### **3.1.3 Operand**

#### **PILOT**

By choosing *FORMAT* = “*XMGRACE*”, one has the pilots of exit used by *xmgrace* in using the *PILOT* key word. This amounts using the functions of export of *xmgrace* via its menu “*File/Print Setup...*”.

The exact list of the pilots available on your waiter is provided by the option “- version” of *xmgrace*.

Possible values of *PILOT*:

- . ”
- : in this case, no pilot is used, the file obtained is the *.agr* or *.dat* of *xmgrace* (file containing them data and directives of the graph),
- . “*POSTSCRIPTP*”, “*EPS*”
- : file postscript full-page or encapsulated,
- . “*PNG*”, “*JPEG*”, “*PNM*”
- : file of the image type,
- . “*PDF*”, “*MIF*”, “*SVG*”
- : formats
- private individuals,
- . “*INTERACTIVE*”
- : no file is turned over if one can open *xmgrace* with the screen.

**NB:** “*JPEG*” and “*pdf*” are not available on the waiter of calculation *EDF* (*clayastr*).

### **3.1.4 Page-setting of the graph common to XMGRACE and AGRAF**

#### **3.1.4.1 Operands**

##### ***BORNE\_X/BORNE\_Y***

*BORNE\_X =*

*Layout of the function in an interval of the X-coordinates given.*

*BORNE\_Y =*

*Layout of the function in an interval of the ordinates given.*

#### **3.1.4.2 Operands**

##### ***ECHELLE\_X/ECHELLE\_Y***

*ECHELLE\_X =*

*Type of scale desired for the X-coordinates, Linear or Logarithmic curve.*

*ECHELLE\_Y =*

*Type of scale desired for the ordinates, Linear or Logarithmic curve.*

#### **3.1.4.3 Operands**

##### ***LEGENDE\_X/LEGENDE\_Y***

*LEGENDE\_X =*

*Caption associated with the x-axis.*

*LEGENDE\_Y =*

*Caption associated with the y-axis.*

#### **3.1.4.4 Operands**

##### ***GRILLE\_X/GRILLE\_Y***

*GRILLE\_X = nx*

*For xmgrace, NOC is the distance between two vertical successive lines of the grid.  
For agraf, nx is the entirety defining the frequency of layout of these lines.*

*GRILLE\_Y = ny*

*Even thing for the horizontal lines of the grid.*

### **3.1.5 Page-setting with the format TABLE**

*One can define here the membership of the printed table: of a traditional table in columns with a format compatible csv or HTML...*

#### **Note:**

*The labels of the columns are suffixées by “\_ + n° of column” (while starting to 0) so to avoid the repetition because the names all of columns must be different.*

*SEPARATOR = separ*

*The separator used between two columns (a space by defect) defines.*

*COMMENT = COM*

*Character inserted at the beginning of line to indicate a line in comment (or titrates, # by defect).*

*DEBUT\_LIGNE = deb.*

*Chain inserted into the beginning of each line (vacuum by defect).*

*FIN\_LIGNE = fine*

*Chain inserted at the end of the line (“\ by defect).*

### ***3.1.6 Key words common to all the formats***

***TITRATE***

***SOUS\_TITRE***

***Allow to define the principal and secondary titles graph or table.***

### ***3.2 Word***

***key***  
***CURVE***

***CURVE***

***Key word factor allowing to print the definite functions or to trace one or more functions in the same graph (a function by occurrence of the key word factor).***

#### ***3.2.1 Complementary attributes for the layout of each function by the software xmgrace or agraf***

***STYLE = sty***

***This key word defines the style of feature of the curve.***

***For xmgrace, the correspondence is as follows:***

***0 step of line 1 continuous feature 2 dotted lines***

***3 short indents 4 long indents***

***5, 6, 7, 8 alternate indents dotted lines***

***For agraf, the styles are:***

***0 line***

***1 dotted lines***

***2 point***

***MARKER = marq***

***This key word defines the type of marker or symbol of the points of the curve.***

***For xmgrace:***

***0 step of marker***

***1 circle***

***2 square***

***3 rhombus***

***4 high triangle***

***5 left triangle***

***6 low triangle 7 right triangle 8 more***

***9 crosses***

***10***

***star***

***For agraf, the markers are:***

***0 circle***

***1 square***

***2 more***

***3 rhombus***

***4 full circle***

***5 full square***

***6 full rhombus 7 cercle+croix 8 losange+croix***

***COLOR = coul***

***This key word defines the color of the curve.***

***For xmgrace, the colors are:***

***0 white***

***1 black***

***2 red***

***3 green***

***4 blue***

**5 yellow**  
**6 brown**  
**7 gray**  
**8 purple**  
**9 cyan**  
**10 magenta**  
**11 orange**  
**12 chestnut**  
**13 indigo**  
**14 turquoise**  
**15**  
**green**  
**dark**

***For agraf, the colors are:***

**0 black**  
**1 red**  
**2 dark green**  
**3 blue**  
**4 magenta**  
**5 cyan**  
**6 green**  
**7 chestnut**  
**8 orange**  
**9 mauve**  
**10 yellow**  
**11 clear chestnut**

***CAPTION = legend***

***Caption given to the function (by defect one recovers the name of the function).***

***FREQ\_MARQUEUR = freqmarq***

***Entirety indicating the frequency of impression of the marker associated with a function. All the im points of discretization of the function, a marker is printed (by defect all points).***

***Instruction manual***

***Operator CREA\_TABLE***

***1 Goal***

***To create a table.***

***This order makes it possible to create a table starting from a function or lists of real numbers. count created has two parameters at least and as many lines as the user wishes it.***

***The lists used to generate the table must have the same number of terms, or it is necessary to indicate the numbers of the lines which one wishes to fill.***

***The function making it possible to fill the cells of the table is tabulée, which means that it is not known that in certain points. It will have to be as a preliminary defined in the command file with assistance of order DEFI\_FONCTION.***

***The concept created by this operator is of type counts or its derived types (tabl\_...).***

*3 Word*

*key*

*FUNCTION*

*3.1 Operand*

*FUNCTION*

*The table is created starting from a function. The first column of the table contains the X-coordinates of function and the second values of the function to the corresponding X-coordinates.*

*3.6 Operand*

*PARA*

*Names of the parameters of the table. This key word is optional: the names of the parameters are then*

*identical to the NOM\_PARA and NOM\_RESU of the function. If it is indicated, its cardinal must be equal to*

*2: name of parameter for the column associated with the X-coordinates, name of parameter for the column associated the ordinates.*

**4 Word  
key  
LIST**

*This key word must be provided at least 2 times: each occurrence makes it possible to define a column of count.*

*The lists do not have necessarily the same cardinal, one uses key word NUME\_LIGN to indicate which lines must be filled.*

**4.1 Operand  
LISTE\_R**

*A column is created in the table starting from a list of reality.*

**4.2 Operand  
LISTE\_I**

*A column is created in the table starting from a list of entirities.*

**3.5 Operand  
LISTE\_K**

*A column is created in the table starting from a list of character strings.*

**4.3 Operand  
TYPE\_K**

*Length of the character strings for case LISTE\_K.*

**4.4 Operand  
NUME\_LIGN**

*When the lists do not have all the same cardinal or to build a table with holes, one uses this key word to specify which lines are filled.*

**4.5 Operand**

## **PARA**

*Name of the parameter of the table associated with the provided list.*

**U4.33.02-B1 Page:**

**4/4**

## **5 Examples**

### **5.1**

**Creation of a table starting from a function**

```
FCT=DEFI_FONCTION (NOM_PARA=' X',  
VALE= (0.0, 5.0, 4.0, 17.5)) ;
```

```
T_FCT=CREA_TABLE (FONCTION=_F (FONCTION=FCT));
```

```
IMPR_TABLE (TABLE=T_FCT);
```

**The impression of the table created is as follows:**

```
X TOUTRESU
```

```
0.00000E+00 5.00000E+00
```

```
4.00000E+00 1.75000E+01
```

### **5.2**

**Creation of a table starting from three lists, heterogeneous types**

```

T_LST=CREA_TABLE (LISTE= (
_F (LISTE_R= (0.0, 4.0), PARA=' X'),
_F (LISTE_R = (5.0, 17.5), PARA=' Y'),);
_F (LISTE_I = (6.7), PARA=' K')

```

```

IMPR_TABLE (TABLE=T_LST);

```

*The impression of the table created is as follows:*

```

X Y K
0.00000E+00 5.00000E+00 6
4.00000E+00 1.75000E+01 7

```

### **5.3**

*Creation of a table with holes*

```

TAB=CREA_TABLE (
LISTE= (
_F (
PARA=' NUME_ORDRE',
LISTE_I= (8,15,156,67),
),
_F (
PARA=' VAR',
LISTE_R= (2. , 15. , 18),
NUME_LIGN= (1,3,4),
),
_F (
PARA=' COMMENT',
LISTE_K= ("VALUE"),
TYPE_K=' K24',
NUME_LIGNE=1,
),
),

```

*The impression of the table created is as follows:*

```

NUME_ORDRE

```

```

VAR
HOW
8 2.00000E+00
VALUE
15 -

```

-  
**156 1.50000E+01**

-  
**67 1.80000E+01**

-

## ***Procedure CALC\_TABLE***

### ***1 Goal***

***To handle the data of the tables to the manner of a spreadsheet.***

***The order makes it possible to carry out operations on the data of the tables. Following operations are currently available:***

.

***Concaténer/To combine two tables,***

.

***To apply a formula,***

.

***To re-elect parameters,***

.

***To filter the lines according to certain criteria,***

.

***To extract certain columns from a table,***

.

***To order the lines,***

***Product a structure of data counts.***

**Procedure CALC\_TABLE**

**Date:**  
**31/01/06**  
**Author (S):**  
**COURTEOUS Mr., F. LEBOUVIER Key**  
**:**  
**U4.33.03-A1 Page:**  
**4/10**

**3 Operands**

**3.1 Operand**  
**COUNT**

**COUNT = matable**

**Name of the initial table on which one will carry out handling**

**3.2 Operand**  
**COMB: concaténer/to combine two tables**

/  
**COMB**

**Key word COMB allows concaténer, to combine two tables between them, with seam on one common parameter list.**

### **3.2.1 Operand COUNT**

**COUNT = table**

**Name of the table whose values must come to overload and/or enrich the initial table.**

### **3.2.2 Operand NOM\_PARA**

**NOM\_PARA = will l para**

**Name of the parameters whose values must be identical in the two tables.**

**Remarks for the combination:**

**Ex: tab\_resu=CALC\_TABLE (TABLE=tab1,  
COMB=\_F (TABLE=tab2,  
NOM\_PARA= (“ABSC\_CURV”, “NODE”)))**

**When ABSC\_CURV and NODE are identical between tab1 and tab2, one inserts the values of tab2 on the line of tab1 (for the other parameters common to the 2 tables, it is thus value of tab2 which crushes that of tab1). If not one adds the line of tab2 at the end of tab1.**

**NOM\_PARA acts like a primary key: if one does not find more once couple (ABSC\_CURV, NODE), the line is added.**

**This operator is not répétable because the order of the occurrences of the key word factor could to modify the final result.**

### **3.3 Operand**

**OPER: To apply a formula**

**/  
OPER**

**Allows to apply a formula whose variables are the parameters of the table and to insert it result in a new column.**

**Note:**

**This operator is répétable.**

### **3.3.1 Operand** **FORMULATE**

*FORMULATE = formula*

*Name of the formula to be applied*

### **3.3.2 Operand** **NOM\_PARA**

*NOM\_PARA = para*

*Name of the new parameter.*

*Instruction manual*

*U4.3- booklet: Function HT-62/06/004/A*

---

### **Code\_Aster** ®

*Version*

8.2

*Titrate:*

*Procedure CALC\_TABLE*

*Date:*

31/01/06

*Author (S):*

**COURTEOUS Mr., F. LEBOUVIER** Key

:

*U4.33.03-A1 Page:*

5/10

### **3.4 Operand** **RE-ELECT: To re-elect parameters of a table**

/

**RE-ELECT**

*The key word RE-ELECTS makes it possible to re-elect one or more parameters of a table.*

### **3.4.1 Operand** **NOM\_PARA**

*NOM\_PARA = will l\_para*

*Name of the parameters: couples values (old name of the parameter, new name of parameter)*

**Note:**

*This operator is répétable.*

**3.5 Operand FILTERS: To filter the lines according to certain criteria**

/  
**FILTER**

*The key word factor FILTER makes it possible to retain in the table only the lines checking some criteria imposed by the user. The occurrences of the key word are added the ones to the others like successive filters. For each occurrence of this key word, one specifies the name of parameter for which one imposes a condition, the type of condition (equality, not-equality, more small.) as well as the value associated with the condition.*

**Note:**

*This operator is répétable.*

**3.5.1 Operand**

**NOM\_PARA**

*NOM\_PARA = para*

*para is the name of the parameter to which the constraint of filtering relates.*

**3.5.2 Operand**

**CRIT\_COMP**

*CRIT\_COMP = crit*

*crit is the type of the constraint of filtering.*

**EQ**

*“equality” for the entirities, the texts, realities or the complexes.*

*For the floating numbers (real or complex), this equality is evaluated with a certain tolerance given by the key words PRECISION and CRITERION.*

*“not-equality” (cf EQ)*

**LT**

***“smaller than”***

***Relations of order:***

***- natural for the entireties and realities***

***- alphabetical for the texts***

***- invalid for the complexes***

**WP**

***“larger than” (cf LT)***

***“smaller or equal to” (cf LT)***

**GE**

***“larger or equal to” (cf LT)***

**VACUUM**

***blank cell***

**NON\_VIDE**

***nonempty cell***

**MAXIMUM**

***the line selected will be that which will have the maximum value***

**ABS\_MAXI**

***the line selected will be that which will have the maximum absolute value***

**MINIS**

***the line selected will be that which will have the minimal value***

**ABS\_MINI**

***the line selected will be that which will have the minimal absolute value***

***Instruction manual***

***U4.3- booklet: Function HT-62/06/004/A***

---

**Code\_Aster ®**

**Version**

**8.2**

***Titrate:***

***Procedure CALC\_TABLE***

***Date:***

***31/01/06***

***Author (S):***

***COURTEOUS Mr., F. LEBOUVIER Key***

**:**

***U4.33.03-A1 Page:***

***6/10***

***3.5.3 Operands***

**VALE/VALE\_I/VALE\_C/VALE\_K**

*These various key words are used according to the type of the column associated with the parameter on which carries the constraint: entirety, reality, complex or text.*

*One gives in argument the value associated with the constraint; for example 12 if one is interested only in sequence number 12.*

*This operand is useless when the types of constraint are used: “VACUUM”, “NON\_VIDE”, “MAXIMUM”, “MINI”,...*

**3.5.4 Operands****CRITERION/PRECISION**

*When the constrained parameter is of floating type (real or complex) and that the type of constraint is the equality (or not-equality), this equality is evaluated with a certain tolerance.*

**PRECISION = eps,**

*eps is the tolerance*

**“RELATIVE” CRITERE=/,**

**|x-xref| < eps\*|xref|**

**/“ABSOLUTE”**

,

**|x-xref|**

**<**

**eps**

**3.5.5 Example of use of the key word FILTERS**

*If one specifies:*

**FILTRE= (\_F (NOM\_PARA= “NODE”, VALE\_K = “N7”),  
\_F (NOM\_PARA= “INST”, CRIT\_COMP= “WP”, VALE= 3.0),  
\_F (NOM\_PARA= “INST”, CRIT\_COMP= “LT”, VALE= 13.0),  
)**

*One thus selects the lines of the table such as the parameter NODE is worth “N7” and such as parameter INST lies between 3. and 13.*

### **3.6 Operand**

**EXTR: To extract certain columns from a table**

/

**EXTR**

*Key word EXTR makes it possible to extract certain columns from a table.*

#### **3.6.1 Operand**

**NOM\_PARA**

**NOM\_PARA = will l\_para**

*Name of the parameters which one wants to extract.*

**Note:**

*This operator is not répétable.*

### **3.7 Operand**

**SORTING: To order the lines**

/

**SORTING**

*The TRI key word makes it possible to order the lines according to values' of the parameters.*

**Note:**

*This operator is not répétable because the order of the occurrences of the key word factor could to modify the final result.*

**Instruction manual**

**U4.3- booklet: Function HT-62/06/004/A**

**COURTEOUS Mr., F. LEBOUVIER Key**

:

**U4.33.03-A1 Page:**

**7/10**

### **3.7.1 Operand**

**NOM\_PARA**

**NOM\_PARA = will l\_para**

**Names of the parameters to which the sorting relates.**

### **3.7.2 Operand**

**ORDER**

**ORDER =/“GROWING”**

**/**

**“DECREASING”**

**This key word is used to specify if one must use an order ascending or decreasing. By defect, one sort by ascending order.**

**The relations of order used are:**

**.**

**the natural order for the entireties and realities,**

**.**

**the alphabetical order for the texts and the names of concepts.**

**Note:**

**One cannot be useful oneself of a parameter complexes to classify the lines of a table.**

**For the parameters of the NODE type (or NETS), the order is alphabetical because these parameters contain the name of the nodes (or of the meshes).**

**If one specifies:**

**TRI=\_F (NOM\_PARA= (“NODE”, “INST”), ORDRE= “GROWING”),**

**One will sort the lines of the table in the alphabetical order of the nodes. If there are several lines corresponding to a given node, the second sort criterion (INST) will be used for**

*to classify these lines.*

### **3.8 Operand INFORMATION**

**INFORMATION = inf**

**Print in the file “message” of additional information if inf=2. Nothing occurs if inf=1.**

: 3/4

### **3 Operands**

#### **3.1 Operand**

**VALE**

**VALE = lr8**

*List realities which will form the structure of data *listr8* result.*

*This list can be built starting from a Python list.*

#### **3.2 Operand**

**BEGINNING**

**BEGINNING**

=

*It is the first reality of the list of realities which one wants to build.*

#### **3.3 Operand**

**INTERVAL**

**INTERVAL**

=

**JUSQU\_A**

=

**r1**

*It is the end of the interval which one will cut out with a constant step.*

**/A NUMBER**

**= nI**

*It is the number of steps which one wants in the interval which ends in r1.*

**/**

**NOT**

**=**

**r2**

*It is the step of division interval.*

**3.4 Operand**

**INFORMATION**

**INFORMATION**

**=**

**I**

*Indicate the level of impression of the results of the operator.*

*1: no impression,*

*2: impression of the list of realities created*

**3.5 Operand**

**TITRATE**

**TITRATE**

**= title**

*Titrate that the user wants to give to his list realities.*

**4 Remarks**

.

*when the key word STEP is used it may be that the number of calculated step is not rigorously entirety. One “will then adapt” the last interval to fall down exactly on the end value (JUSQU\_A). If for that, one modifies the step value of more than 1/1000 one emits an alarm,*

.

*caution: this order produces a structure of data listr8 which can only be used in the orders awaiting such structures of data and not in those which wait lists of realities (notation: l\_R).*

### ***3 Operands***

#### ***3.1 Operand***

***GRID***

***GRID***

***=***

***my***

***Name of the grid for which the curvilinear X-coordinate is defined.***

#### ***3.2 Operands***

***NOEUD\_INIT and NOEUD\_FIN***

***NOEUD\_INIT = nor/NOEUD\_FIN = nf***

***The function is defined on the whole of the grid. The nodes “INIT” and “END” allow to define the zone of application of the profile speed. Apart from this zone, the value of the function is null.***

#### ***3.3 Key word***

***QUICKLY***

***QUICKLY***

***Key word factor, it makes it possible to define the profile speed.***

***PROFILE***

***This operand, associated operands VALE and NB\_BAV, makes it possible to define a “standard” profile:***

***“UNIFORM” or “LEONARD”.***

***/***

**VALE = vale**

*Allows to define the level of the function, if the standard profile is “UNIFORM”.*

/  
**NB\_BAV**

*If the profile is of type “LEONARD”, NB\_BAV defines a “standard” profile stored in one catalogue.*

**Note:**

*BAV (Vibratory Anti Bar) is a terminology related to the tubes of generator of vapor. NB\_BAV corresponds to the number of anti-vibratory bars being in the zone of obtaining the profile.*

**3.4 Operand**  
**Interpol**

**Interpol**

*Type of interpolation of the function enters the values of parameter of the field of definition.*

· “FLAX”:

*linear,*

· “LOG”:

*logarithmic curve,*

· “NOT”:

*one does not interpolate (and thus the program will stop if one asks value of the function for a value of the parameter for which it was not defined).*

***Operator FONC\_FLUI\_STRU***

***1 Goal***

*To create a constant function parameterized by the curvilinear X-coordinate. This function gives the value of coefficient of mass added for a configuration of the type “beam of tubes under flow transverse”.*

*This function is used downstream by operator DEFI\_MATERIAU [U4.43.01], key word factor ELAS\_FLUI. Product a concept of the function type.*

**3 Operands**

**3.1 Key word**

**TYPE\_FLUI\_STRU**

**TYPE\_FLUI\_STRU = typeflui**

**Concept of the type [type\_flui\_stru] produced by operator DEFI\_FLUI\_STRU [U4.25.01], providing the value of the coefficient of added mass  $C_m$ .**

**Note:**

**The  $C_m$  value can be imposed via key word COEF\_MASS\_AJOU appearing in order DEFI\_FLUI\_STRU. If the coupling fluidelastic is taken in count, the coefficient of added mass can be calculated by the operator according to other characteristics of the beam.**

***Operator FONC\_FLUI\_STRU creates a concept of the type [function] which is then directly usable by DEFI\_MATERIAU [U4.43.01], key word ELAS\_FLUI.***

***The function constant, is parameterized by the curvilinear X-coordinate, and gives the Cm value.***

***The combined use of operators FONC\_FLUI\_STRU then DEFI\_MATERIAU option ELAS\_FLUI is necessary when one studies a configuration of the type “beam of tubes under transverse flow”, and it is allowed only for this type of configurations.***

*:*  
*U4.36.01-G Page*  
*: 5/6*

#### *5 Remarks* *of use*

*In addition to the produced concept of `tabl_intsp` type, the operator creates concepts of the `fonction_C` type associated the defined functions, of the matrix interspectrale. These functions are accessible to*

*the user using order **RECU\_FONCTION** [U4.32.03] or by printing them with **IMPR\_TABL** [U4.91.03]. They will be printed with format **MODULE\_PHASE**.*

*The names of the parameter and result of the functions have as a default value “**FREQ**” and “**DSP**”.*

## **5.1**

### *Syntax of the file*

*The information read on the file is made up of three parts:*

•  
*a key word of head of imposed chapter: **INTERSPECTRE**.*

•  
*the key word **DIM**, dimension of the matrix.*

•  
*“subfiles defining “complex functions. Each subfile starts with key word **FONCTION\_C** and ends in **FINSF**.*

•  
*the file ends obligatorily in **END**.*

## **5.2 Descriptor**

### **5.2.1 Key word describing caractérisques matrix**

***DIM = dim***

*Entirety makes it possible to define the dimension of the matrix.*

***Note:***

*The sign “=” is obligatory.*

### **5.2.2 Key word describing a fonction\_C**

***Notice preliminary:***

*“, the number of functions to be defined is equal to:  
 $N = (dim * (dim + 1)) / 2$ , since the matrix considered is “**SQUARE**”.*

*N functions are defined by their indices **I** and **J** in the matrix. Only the triangular part higher of the matrix is defined, (indices (1,1); (1,2); (2,2); (1,3); ... (N, N)).*

***FONCTION\_C***

***I = whole***

*index line of the function in the matrix.*

*J = whole*

*index column of the function in the matrix.*

*NB\_POIN = whole number of points of the FUNCTION*

*VALUE =*

*3\*NB\_POIN real must be present. The reading of the values is carried out  
line  
with  
line.*

*On each line are defined in the following order:*

*.  
the value of the parameter, the real part of the result, the imaginary part of the result  
(FORMAT = "REEL\_IMAG"),  
or*

*.  
the value of the parameter, the module of the result, the phase of the result  
(FORMAT = "MODULE\_PHASE"),*

*Note:*

*For format MODULE\_PHASE, the phase is given in degree.*

### **3.4 Operands**

#### ***PROL\_DROITE and PROL\_GAUCHE***

*PROL\_DROITE and PROL\_GAUCHE =*

*Define the type of prolongation on the right (on the left) of the field of definition of the variable:*

*.*

*“CONSTANT” for a prolongation with the last (or first) value of function,*

*.*

*“LINEAR” for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),*

*.*

*“EXCLUDED” if the extrapolation of the values apart from the field of definition of parameter is prohibited (in this case if a calculation requires a value function out of the field of definition, the code will stop in fatal error).*

*For example:*

*.*

*PROL\_DROITE = “CONSTANT”, PROL\_GAUCHE = “CONSTANT”*

*y*

*X*

*X*

*X*

*X*

*X*

*1*

*2*

*n-1*

*N*

.

*PROL\_DROITE = "LINEAR", PROL\_GAUCHE = "EXCLUDED"*

*y*

*X*

*X*

*X*

*X*

*1*

*x2*

*n-1*

*N*

**Note:**

*The type of prolongation and interpolation are independent one of the other.*

*Instruction manual*

*: 6/8*

**3.5 Operand**

## ***Interpol***

*Interpol*

=

*Type of interpolation of the function enters the values of the field of definition of the function: one type for the interpolation of the parameter and for the interpolation of the function. This is obtained in providing a list of texts among:*

*Interpol*

=

*(“FLAX”,  
“LOG”)*

*“FLAX”: linear,*

*“LOG”: logarithmic curve,*

*“NOT”: one does not interpolate (and thus the program will stop if for the value is asked function for a value of the parameter where it was not defined).*

### ***Note:***

*If only one value is specified, it is taken into account at the same time by the interpolation of parameter and of the function. Interpol = “LOG” is equivalent to (“LOG”, “LOG”).*

## **3.6 Word**

***key***

***CONSTANT***

***/CONSTANT***

=

*Key word factor which makes it possible to define a function of the matrix interspectrale like a noise white (constant).*

*All the key words under this key word factor have the same direction as for the key word factor KANAI\_TAJIMI except AMOR and FREQ\_MOY which do not have a direction here.*

## **3.7 Operand**

***Caution:***

***This average adapted perfectly to the “real” signals, results of a measurement is not appropriate not without precaution for functions close to a sine (the frequency of the average must***

*to be much higher than the frequency of the signal.*

**Note:**

*If the treated signals come from operator GENE\_FONC\_ALEA via possibly it calculation of a dynamic response (operator DYNA\_TRAN\_MODAL for example), then it is advised to treat each pulling of GENE\_FONC\_ALEA independently. In this case, it is necessary to choose durations of analysis and shift equal to the duration of each pulling GENE\_FONC\_ALEA (cf GENE\_FONC\_ALEA [U4.36.05]).*

### **3.3 Operand**

**NB\_POIN**

$NB\_POIN = N_p$

*A number of points of the parameter for one duration of analysis. For each point the functions will be calculated according to the type of definite interpolation and prolongation. The number of points must be a power of 2 (calculation of the fast transform of Fourier).*

**Note:**

*If the signals consist of a number (power of two) sufficient of points with one not constant, it is preferable to choose this number to avoid interpolations which can generate artifacts. In particular, if the treated signals come from the operator GENE\_FONC\_ALEA via possibly the calculation of a dynamic response (operator DYNA\_TRAN\_MODAL for example), this number will correspond to the double of the number of points informed in GENE\_FONC\_ALEA key word NB\_POIN or obtained by INFO=2 in GENE\_FONC\_ALEA (cf GENE\_FONC\_ALEA [U4.36.05]).*

### **3.4 Operand**

**FUNCTION**

**FUNCTION**

*: 4/8*

*3.4 Operand*

*DUREE\_TIRAGE*

*DUREE\_TIRAGE*

*=*

*duration*

*[R]*

*Lasted of the signal to generate, for each pulling (the total duration will be thus NT X duration).*

*If key word DUREE\_TIRAGE is not present, the duration of the signal to be generated is calculated by*

***duration = 1 / F***

***where F***  
***is the step in frequency of the interspectre (not minimum of origin of***  
***the interspectre, or not calculated starting from key words `FREQ_INIT`, `FREQ_FIN` and `NB_POIN`).***

***Note:***

***The generated signals start at moment 0. with a zero value.***

***Note:***

***To obtain the desired duration, the algorithm of generation adjusts the number of points used in the FFT (cf [§3.6](#) Operand `NB_POIN`) and the interspectre prolongs if need be with beyond frequencies min and max by zero values.***

### ***3.5 Operands***

***`FREQ_INIT`/`FREQ_FIN`***

***`FREQ_INIT`***

***=***

***$f_i$***

***[R]***

***`FREQ_FIN` = `FF`***

***[R]***

***First and last values of frequency for which the interspectre will be taken into account.***

***The presence of these key words causes to truncate the interspectre. If the key words are not present, in fact the values of minimal and maximum frequency of the interspectre are used.***

### ***3.6 Operand***

***NB\_POIN***

***NB\_POIN***

***=***

***nb\_poin [I]***

***A number of points of discretization of the interspectre to be used in the algorithm of generation.***

***This number must be a power of 2 but it corresponds to the number of points of the transform of fast Fourier reverses used by the algorithm of generation. If such is not the case, it is power of 2 immediately above than nb\_poin which is retained.***

***If key word NB\_POIN is not present, the number of points is calculated so that the theorem of Shannon is respected, i.e. that  $1/T$***

***> 2 fmax, where  $T$***

***is the step in time of the signal with***

***to generate (which depends on NB\_POIN and DUREE\_TIRAGE) and where fmax is the maximum frequency***

***reserve of the interspectre.***

***Suggestion:***

***It is advised not to specify the number of points, the coded algorithm choosing in this case automatically the optimal value. In particular, if key words DUREE\_TIRAGE and NB\_POIN are not present, then one is assured that the generated signal is coherent with time with the step of discretization of the interspectre and with the maximum frequency. However, if the user wants to specify NB\_POIN, the two remarks which follow must help there.***

***Note:***

***If key words***

***duration***

***DUREE\_TIRAGE and NB\_POIN are present then one a:  $T$***

***=***

***·  
2×nb\_poin***

***In this case, if nb\_poin too small by report/ratio is lasted so that the theorem of Shannon is respected; then an alarm is emitted and it is the minimum number of points allowing the respect of the theorem of Shannon who is retained. The value specified by NB\_POIN is thus taken into account only when it is higher than the value minimum. In imposing a number of points raised, one can force the signal to have a step of discretization in time smaller than that by defect. It is necessary then to be conscious that the discretization of temporal is finer than the maximum frequency of the interspectre allows it theoretically.***

***Instruction manual***

**U4.3- booklet: Function**  
**HT-66/05/004/A**

---

**Code\_Aster** ®

**Version**

**7.4**

**Titrate:**

**Operator** *GENE\_FONC\_ALEA*

**Date:**

**08/02/05**

**Author (S):**

**S. CAMBIER, A. DUMOND, G. JACQUART** *Key*

**:**

**U4.36.05-G** *Page*

**: 5/8**

**Note:**

*If INTERPOL='NON' and if nb\_poin is not compatible with the interspectre, an alarm is emitted and a power of 2 ad hoc is selected.*

**Note:**

*The number of points constituting the generated signals is equal to twice the number of points of discretization of the interspectre, and thus with twice nb\_poin when the key word is informed. This number of points is useful to know for a posterior use in [CALC\\_INTE\\_SPEC \[U4.36.03\]](#) (cf [\[§3.9\]](#) “Operand INFORMATION” and [\[§5\]](#) “Examples”).*

### **3.7 Operand**

**NB\_TIRAGE**

**NB\_TIRAGE**

**=**

**NT**

**[I]**

*A number of pullings which must contain the generated temporal signals. The signals results will contain NT end to end put statistically independent pullings.*

*One can then post-treat the results obtained starting from these signals generated with the operator [CALC\\_INTE\\_SPEC \[U4.36.03\]](#), cf [\[§5\]](#) “Examples”.*

**Caution:**

*If key word DUREE\_TIRAGE is present, the total duration of signal will be NT X duration. However, it is not of course equivalent to generate 1 pulling of duration NT X durée\_tirage and NT pullings of end to end put durée\_tirage duration. In particular,*

*in the second case, there is statistical independence between the various sections of duration D, however not in the first case.*

**3.8 Operand****INIT\_ALEA****INIT\_ALEA****=****nor****[I]**

*Cause initialization in its nor-ième term of the continuation of pseudo-random numbers employed for the generation of the signals.*

*If key word INIT\_ALEA misses, the terms used of the continuation are those immediately consecutive with those already used. If no term were still used, the continuation is initialized with sound first term.*

**Suggestion:**

*With less than one particular use, it is advised not to inform key word INIT\_ALEA in the operators according to: GENE\_FONC\_ALEA, GENE\_VARI\_ALEA and GENE\_MATR\_ALEA.*

*In this case, with the first call to the one of these operators, the continuation of pseudo numbers random is initialized in its first term. The omission of key word INIT\_ALEA to each one calls of these operators in the command file guarantees independence statistics of the pseudo-random numbers used.*

**Note:**

*The germ of the continuation remains identical of one execution to the other of Code\_Aster; results thus remain rigorously identical (one can thus test nonthe regression of results statistics not converged). If one wishes to generate results statistically independent from one execution to another, then it is necessary to use key word INIT\_ALEA with values raising the number of terms used in the former executions.*

**Caution:**

*The generator of random variable used is that of the module “random” of Python. It depends on the version of Python exploited by Code\_Aster. Not converged results statistically can thus vary from one version to another of Code\_Aster or a punt form with the other, if the version of Python is not the same one and that between the two versions it modulate random evolved/moved (case between Python 2.1 and 2.3).*

**Note:**

*In version Python 2.3, the period of the generator is 2 \*\* 19937-1 [bib1].*

## **1 Goal**

**To generate achievements of generalized matrices considered as random for structures or of the substructures. The law of probability of the matrices is built according to the principle of the maximum of entropy by considering information available (average and coefficient of variation) and theirs algebraic properties (definite symmetry positivity) [R4.03.05].**

**Product a structure of data *matr\_asse\_gene\_R* or *macr\_elem\_dyna* according to the type of data input.**

### **3 Operands**

*With or without under-structuring, this operator consists in in fine generating achievements of one or several noted random matrices in a generic way [A]. [A] is a random variable with value in the whole of the positive definite real matrices of dimension (N, N) whose law is parameterized by its average value []*

*With and its scatter coefficient [R4.03.05].*

#### **3.1 Word**

*key*

**MATR\_MOYEN**

**MATR\_MOYEN = average**

*average indicates the average matrix []*

*With random matrix [A].*

*So average is of type [matr\_asse\_gene\_R], then []*

*A is obtained by projection of one*

*stamp average assembly of the average model to the finite elements on a given number of modes clean of the dynamic system (operator MACRO\_PROJ\_BASE for example). []*

*With and them*

*achievements of [A] generated by GENE\_MATR\_ALEA can thus be matrices of masses, generalized stiffness or damping.*

**Caution:**

*The average matrix ([])*

*With) must be stored in mode of full storage (operator*

*NUME\_DDL\_GENE, key word STOCKAGE=' PLEIN' or operator MACRO\_PROJ\_BASE, key word PROFIL=' PLEIN').*

*So average is of type [macr\_elem\_dyna] (under-structuring), then []*

*A is a concept*

*containing the matrices of rigidity, mass and possibly of damping projected on base modal substructure supplemented by the matrices of connection of the interfaces, the model means.*

#### **3.2 Word**

*key*

**COEF\_VAR**

**COEF\_VAR =**  
/  
/  
**0.1**  
**[DEFECT]**

*This key word informs the parameter of control of the dispersion of the generalized matrix random [A] which can be of mass, stiffness or dissipation. This coefficient of variation is defined by:*

**2**  
**(N +)**  
**1 \* A F**  
**E [**  
**{A} - [ ] 2**  
**WITH F} 1 2**

**=**

can also be written:

2
E {[G] - [
With
G WITH F}
=

2
[G

**WITH F**

*with [L A] the lower triangular matrix resulting from the factorization of Cholesky*

$$[A] = [L] T$$

*With*

*[GA] [IT] of the average matrix {*

*E [A]*

*] = [ ]*

*A.*

*One must have (cf [R4.03.05]):*

*N + 1*

*0*

*0*

*< <*

*With*

*,*

*N + 5*

*0*

*where N NR is a constant of the probabilistic model selected so that  $N < N$*

*0*

*0*

*.*

**COEF\_VAR\_RIGI =/R**

**[R]**

**/ 0.1**

**[DEFECT]**

*This key word informs the parameter R of control of the dispersion of the random matrix of rigidity of a substructure. This coefficient of variation is defined in a way identical to definition given for key word COEF\_VAR.*

**COEF\_VAR\_MASS =/R**

**[R]**

**/**

**0.**  
**[DEFECT]**

*This key word informs the parameter **R** of control of the dispersion of the random matrix of mass of a substructure. This coefficient of variation is defined in a way identical to definition given for key word **COEF\_VAR**.*

**COEF\_VAR\_AMOR =/R**

**[R]**

**/**

**0.**  
**[DEFECT]**

*This key word informs the parameter **R** of control of the dispersion of the random matrix of dissipation of a substructure. This coefficient of variation is defined in a way identical to definition given for key word **COEF\_VAR**.*

**3.3 Operand**  
**INIT\_ALEA**

**INIT\_ALEA**

**=**

**nor**

**[I]**

*Cause initialization in its **nor**-ième term of the continuation of pseudo-random numbers used for the generation of the matrices.*

*If key word **INIT\_ALEA** misses, the terms used of the continuation are those immediately consecutive with those already used. If no term were still used, the continuation is initialized with sound first term.*

**Recommendation:**

*With less than one particular use, it is advised not to inform key word **INIT\_ALEA** in the operators according to: **GENE\_FONC\_ALEA**, **GENE\_VARI\_ALEA** and **GENE\_MATR\_ALEA**.*

*In this case, with the first call to the one of these operators, the continuation of pseudo numbers random is initialized in its first term. The omission of key word **INIT\_ALEA** to each one calls of these operators in the command file guarantees independence statistics of the pseudo-random numbers used.*

***Instruction manual***

Operator GENE\_MATR\_ALEA

Date:

22/02/06

Author (S):

**S. CAMBIER, C. DESCELIERS** Key

: U4.36.06-C1 Page:

5/6

**Note:**

*The germ of the continuation remains identical of one execution to the other of Code\_Aster; results thus remain rigorously identical (one can thus test nonthe regression of results statistics not converged). If one wishes to generate results statistically independent from one execution to another, then it is necessary to use key word INIT\_ALEA with values raising the number of terms used in the former executions.*

**Caution:**

*The generator of random variable used is that of the module “random” of Python. It depends on the version of Python exploited by Code\_Aster. Not converged results statistically can thus vary from one version to another of Code\_Aster or a punt form with the other, if the version of Python is not the same one and that between the two versions it modulate random evolved/moved (case between Python 2.1 and 2.3).*

**Note:**

*In version Python 2.3, the period of the generator is  $2^{19937-1}$  [bib1].*

**4 Example**

***By call, the order generates only one realization of the random matrix to simulate. For to generate several achievements of the same random matrix, it is necessary to repeat the order without to change its parameters or to place the order in a loop of the process control language of Code\_Aster - the language python.***

*In the following example, one generates NS achievements of a random matrix of average value MATR\_MOYEN with one = 0.1. These achievements are then used as values of matrix of mass.*

*ns=100*

*for K in arranges (1, ns+1):*

*# Generation*

*MAT\_ALEA=GENE\_MATR\_ALEA (  
MATR\_MOYEN=MAT\_MOY,  
COEF\_VAR=0.1,  
)*

*DYN=DYNA\_TRAN\_MODAL (*

*... MASS\_GENE=  
MAT\_ALEA,  
)*

*# Here for example, statistical processing of DYN*

*TO DESTROY (CONCEPT=\_F (NOM= (DYN, MAT\_ALEA)))*

*# End of the loop (indentation)*

*For more complete examples, to consult the cases test SDNS01 [V5.06.001], SDNL105d [V5.02.105] and SHLS200a [V2.06.200], like [U2.08.05].*

For to generate several achievements of the same random variable, it is necessary to repeat the order without to change its parameters or to place the order in a loop of the process control language of Code\_Aster - the language Python. Each realization is statistically independent of the others achievements.*

*In the following example, one generates NS achievements of a random variable gamma of average value 25000, of support and scatter coefficient 0.1 positive realities. These achievements are then used as values of stiffness of shock.*

*ns=100*

*for K in arranges (1, ns+1):*

*# Generation*

*KN = GENE\_VARI\_ALEA (TYPE=' GAMMA',*

*BORNE\_INF =0.,*

*VALE\_MOY =25000.,*

*COEF\_VAR =0.1,*

*)*

*# Extraction of the value in the produced table*

*VKN = KN ["NO.", 1]*

*DYN=DYNA\_TRAN\_MODAL (*

*...*

*CHOC=\_F (*

*...*

*RIGI\_NOR = VKN,*

...  
)  
)

*# Here for example, statistical processing of DYN*

*TO DESTROY (CONCEPT=\_F (NOM= (DYN, KN)))*

*# End of the loop (indentation)*

*For more complete examples, to consult [U2.08.05] or the case test SDNS01 [V5.06.001].*

## ***1 Goal***

***To define the modelled physical phenomenon (mechanical, thermal or acoustic) and the type of elements finished.***

***This operator allows to affect modelings on whole or part of the grid, which defines:***

***.  
degrees of freedom on the nodes (and the equation or the conservation equations associated),***

***.  
types of finite elements on the meshes,***

***.  
possibly:***

***-  
functions of interpolation on the meshes,***

***-  
points of integration of GAUSS on these meshes.***

***The possibilities of the easily affected finite elements are described in the booklets [U3].***

***The types of meshes are described in the document [U1.03.02].***

***Product a structure of data of the model type.***

### **3 Operands**

#### **3.1 Operand**

##### **GRID**

**GRID = my**

*Name of the associated grid on which one affects the elements.*

**Note:**

*For axisymmetric modelings, the axis of revolution is the axis Y of the grid. All the structure must be with a grid in X 0.*

#### **3.2 Word**

**key**

**AFFE**

**/AFFE**

*Defines the entities of the grid and the types of elements which will be affected for them. For each occurrence, one can introduce a list of modelings. The rule of overload applies between various modelings, from left to right.*

**For example:**

**AFFE=\_F (**

**TOUT=' OUI', PHENOMENE=' MECANIQUE', MODELISATION= ("AXIS", "AXIS\_SI"),**

**Various modelings “overload” the ones the others: AXIS\_SI overloads**

*AXIS on the meshes where AXIS\_SI exists.*

*Note:*

*The code stops in <F> error if modelings of the list are not very of even "dimension" (for example MODELISATION= ("3D", "D\_PLAN")). Moreover, for an occurrence of AFFE, the specified meshes whose dimension is that of the dimension of modeling must be all affected. If not the code emits a <A>larme. This alarm protects the user who uses modelings "with holes ". If for example, it uses only modeling AXIS\_SI on a grid containing only TRIA6.*

*The entities of the grid are specified by the operands:*

*Operands*

*Contents/significance*

*ALL*

*Assignment with the totality of the meshes (but not nodes!!)*

*GROUP\_MA*

*Assignment with a list of groups of meshes*

*GROUP\_NO*

*Assignment with a list of groups of nodes (see remark)*

*NET*

*Assignment with a list of meshes*

*NODE*

*Assignment with a list of nodes (see remark)*

*Note:*

*The use of elements being based only on nodes does not allow to affect materials via AFFE\_MATERIAU. So these elements are not usable neither in STAT\_NON\_LINE [U4.51.03] nor in DYNA\_NON\_LINE [U4.53.01]. In this case, it is necessary to create meshes as a preliminary. POI1 using key word CREA\_POI1 of CREA\_MAILLAGE [U4.23.02].*

*The use of such elements is thus reserved for linear calculations, on discrete elements, of which all the characteristics are affected by AFFE\_CARA\_ELEM.*

***Date:***

**31/01/06**

**Author (S):**

**J. Key PELLET, J.M. PROIX**

**:**

**U4.41.01-II Page**

**: 7/8**

### **3.3 Word**

**key**

**AFFE\_SOUS\_STRUC**

**/AFFE\_SOUS\_STRUC**

**Is usable only for one using model of the static substructures [U1.01.04].**

**/**

**NET = l\_mail**

***l\_mail is the list of the super-meshs which one wants to affect in the model. As for the finite elements, it is not obligatory to affect all the meshs of the grid. It is AFFE\_MODELE which confirms which are the substructures which will be used in model. The difference with the traditional finite elements is that on the super-meshs, one chooses neither MODELING nor the PHENOMENON because the macronutrient (built by the operator MACR\_ELEM\_STAT [U4.62.01]) who will be affected on the super-mesh has its own modeling and its own phenomenon (those which were used to calculate it).***

**/**

**ALL**

**=**

**“YES”**

**All them (super) meshs are affected.**

### **3.4 Operand**

**VERIF**

**VERIF:**

**Value**

**Contents/significance**

**“MESH”**

*check the assignment with all the meshes requested if not error*

**“NODE”**

*check the assignment with all the nodes requested if not error*

*By defect: no checking is carried out.*

#### **4 Phase of execution**

*From the key words PHENOMENON and MODELING, one creates a structure of data specifying it type of element attached to each mesh. There are possibly creations of meshes additional of type POI1 when assignments are made on nodes or groups of nodes. These meshes are not accessible to the user. This is why it is strongly advised to use CREA\_MAILLAGE [U4.23.02] to create meshes POI1 usable in the file of order (for STAT\_NON\_LINE for example).*

*A brief recall of the assignments is systematically printed (INFO=1) in the file message.*

*For example:*

**ON THE 612 MESHES OF GRID MA  
A the ASSIGNMENT OF 612 IS ASKED FOR  
ONE A PU TO AFFECT 612 OF THEM**

**MODELING FINITE ELEMENT STANDARD MESH NUMBERS**

**3D MECA\_TETRA4 TETRA4 52**

**3D MECA\_PENTA6 PENTA6 16**

**...**

**Generals**

**MODEL and VERIF**

**3.1 Operand**

**MODEL**

**MODEL = Mo**

**Concept of the model type, produced by the operator AFFE\_MODELE [U4.41.01] on whom are affected characteristics of the elements. Let us note that the model must contain explicitly with less one of the elements of structure, on which will carry the assignment (if not calculation stops).**

**3.2 Operand**

**VERIF**

**VERIF**

**=/"MESH"**

**/**

**"NODE"**

**Argument Significance**

*Check that the type of element supported by the meshes, to which one wants to affect a characteristic, is compatible with this "MESH" characteristic (including the orientations). In the contrary case, stop with error message.*

*Check that the nodes to which one wants to affect a characteristic "NODE" nodal support a type of element compatible with this (only with characteristic. In the contrary case, stop with error message. DISCRETE)*

### **3.3 Operand INFORMATION**

#### **INFORMATION**

=

/ 2

*Print on the file "MESSAGE", for all the elements, the list of values assigned to the elements:*

- angles of orientation in degrees (beams and discrete),*
- characteristics of the cross sections of beams and of bars,*
- impressions of the elementary matrices (discrete).*

### **Definition of the field of assignment**

**The choice of the elements of the model  $M_0$  to which the assignment relates makes in two stages:**

**1) the choice of the type of element concerned with the assignment (BEAM, DISCRETE,...),**

**2) meshes (of the type of definite element) to affect.**

**The choice of the key word factor defining the type of elements (BEAM, DISCRETE,...) imply that it exist in the model the types of adapted elements (checking carried out systematically).**

**The types of elements concerned depend on modeling:**

**· MECHANICAL phenomenon**

**Key word**

**Assignment of values**

**Two methods are usable to affect values of characteristics:**

**· traditional method: operand whose name evokes the treated characteristic followed by a value or of a list of values. Examples:**

**HULL = \_F (THICK = 1.E-2,**

**GROUP\_MA = "G1"),**

**HULL = \_F (ANGL\_REP = (0. , 90.), GROUP\_MA = "G2"),**

**· for the assignments relating to BAR, BEAM and DISCRETE, like ORIENTATION for elements of beam and discrete elements, the great number of characteristics which can be affected led to a better adapted syntax:**

**CARA = (...) # lists names of characteristics**

**VALE = (...) # lists values corresponding to the characteristics**

**One gives an illustrative example below this case.**

**0,4**

**0,05**

**0,02**

***COQUE\_D\_PLAN, COQUE\_3D, integrations are done by taking of account the variations in function thickness.***

***OFFSETTING***

***=/E,***

***/0.***

*The distance between surface with a grid and average surface defines, in the direction of the normal (modelings DKT, DST, GRID).*

**INER\_ROTA**  
= "YES"

*Taking into account of the inertia of rotation for modeling DKT, DST and Q4G. It is obligatory in the event of offsetting. One can omit this key word for thin hulls, where terms of inertia of rotation are negligible compared to different in the matrix of mass [R3.07.03].*

**COEF\_RIGI\_DRZ = KRZ,**

*KRZ is a coefficient of fictitious rigidity (necessarily small) on the degree of freedom of rotation around the normal with the hull. It is necessary to prevent that the matrix of rigidity is singular, but must be selected smallest possible. The default value (1.E-5) is appropriate for majority of the situations (it is a relative value: rigidity around the normal is equal to KRZ time the diagonal minor term of the matrix of rigidity of the element).*

**Note:**

*Attention, in STAT/DYNA\_NON\_LINE, this coefficient can involve iterations of Newton additional (more than one iteration for a linear problem for example).*

**8.3.3 Operand**  
**ANGL\_REP**

**ANGL\_REP = (,)**,

*This key word is used for the definition of a local reference mark in the tangent plan in any point of a hull.*

*The construction of the local reference mark is done using the two "nautical" angles and (provided in degrees) which define a vector  $v$  whose projection on the tangent level with the hull fixes direction  $xl$ .*

*The vector  $V$  is defined in the total reference mark (O, X, Y, Z) by two rotations and:*

**Y**  
**Z**  
**YI**

**X**

**I**  
**V**

**O**  
**X**

**O**  
**XI**

**Z**  
**V**  
**Y1**  
**Y**  
**X**

***Appear 8.3.3-c***

*One can define a single vector  $V$  for all the structure, or one by zone (key words  $GROUP\_MA/MESH$ ).*

*The construction of the local reference mark in a point of an element of hull is carried out starting from  $V$ , of following way:*

- the projection of  $V$  on the tangent level provides the axis  $x_l$ ,*
- the normal in tangent plan  $N$  is known for each element.*

*The local reference mark is thus:  $(P, x_l, y_l, z_l)$  with:  $x_l = XR$ ,  $z_l = N$  and  $y_l$  supplements the trihedron.*

*$z_l = N$   
 $V$   
 $y_l$   
 $P$   
 $x_l$   
 tangent plan*

*Important remark:*

*The definition of this reference axis is useful:*

- on the level it postprocessing, to define the local trihedron in which the efforts are expressed generalized or constraints. The user will have to take care that the selected reference axis does not find itself parallel with the normal of certain meshes of the grid: (Example: In case or  $ANGL\_REP = (0. , 0.)$  by defect for a parallel plate in plan  $(Y, Z)$  of the reference mark  $TOTAL$  an error message is transmitted during the calculation of option “ $EFGE\_ELNO\_DEPL$ ” of  $CALC\_ELEM [U4.81.01]$ ). The possibility of defining a posteriori a group of meshes of which normal is in a given solid angle is possible by order  $DEFI\_GROUP [U4.22.01]$ ,*
- to lay down the orientation of fibres of a multi-layer hull (cf operator  $DEFI\_COQU\_MULT [U4.42.03]$ ).*

### **8.3.4 Operand** **$COQUE\_NCOU$**

*A number of layers used for integration in the thickness of the hull, the operators  $STAT\_NON\_LINE$  and  $DYNA\_NON\_LINE$  (modelings  $DKT$ ,  $COQUE\_3D$ ,  $COQUE\_AXIS$ ,  $COQUE\_C\_PLAN$ ,  $COQUE\_D\_PLAN$ ).*

### **9.3 Rules**

#### **of use**

#### **Note:**

***The orientation of the elements of beams is done by the key word ORIENTATION [§10]. The angle of gimlet***

***(which makes it possible to direct the transverse section of the beam around its neutral fibre) is always given to direct the principal axes of the section what is not very practical because these axes are in general unknown before the calculation of the geometrical characteristics of the section (cf MACR\_CARA\_POUTRE [U4.42.02]).***

- It is possible starting from version 6 to directly provide (via variables python) them characteristics of the sections (general) resulting from a calculation with MACR\_CARA\_POUTRE.***

***This******is implemented in test SLL107F.***

- The various names of characteristics arguments of operand CARA are described further for each argument of the operand SECTION.***

- For a given mesh:***

- One cannot overload a type of variation of section (constant or variable) by another.
- One cannot overload a type of section (CIRCLE, RECTANGLE, GENERAL) by another.
- For the beams non-prismatic, the names with suffix 1 or 2 are incompatible with names without suffix. Example: A is incompatible with A1 and A2.
- "H" is incompatible with "HZ" and "HY" (like H1, H2,...)
- "EP" is incompatible with "EPY" and "EPZ" (like EP1, EP2,...).
- "RY", "RZ" and "RT" intervene only for the calculation of the constraints.

## **9.4 Operands**

### **9.4.1 Operand**

**VARI\_SECT**

*Allows to define the type of variation of section between the two nodes ends of the element of beam (elements **POU\_D\_E** and **POU\_D\_T** [R3.08.01]).*

*The possibilities are:*

*Section Closely connected Homothetic*

*ring not yes*

*rectangle*

*yes (according to Z)*

*yes*

*general not*

*yes*

- *“Closely connected” means that the surface of the section varies in a linear way between the two nodes.  
dimensions in the direction are there constant (HY, EPY) and that in direction Z vary linearly (HZ1, HZ2, EPZ1, EPZ2).*
- *“Homothetic” means that 2 dimensions of the section vary linearly between values given to the two nodes, the surface of the section thus evolves/moves in a quadratic way.*

#### **9.4.2 Operand**

##### **MODI\_METRIQUE**

*Allows to define for the elements PIPE the type of integration in the thickness (modelings TUYAU\_3M, TUYAU\_6M):*

- *MODI\_METRIQUE = “NOT” resulted in assimilating in integrations the ray to the average radius. This is thus valid for the pipes low thickness (relative with the ray),*
- *MODI\_METRIQUE = “YES” implies a complete integration, more precise for pipings thick, but being able in certain cases to lead to oscillations of the solution.*

#### **9.4.3 Operand**

## 9.5 Operand

**FCX**

FCX

=

$f_v$

Assignment of a function describing the dependence of the force distributed with respect to the speed of wind relative (see test SSNL118 [V6.02.118]). The loading of the wind type is applicable on elements of bar of cable and beam (modelings POU\_D\_E, POU\_D\_T, POU\_D\_T, POU\_D\_TG, POU\_D\_TGD, POU\_D\_TGM).

## 9.6 Operands

**TUYAU\_NSEC/TUYAU\_NCOU**

TUYAU\_NSEC =/nsec,

TUYAU\_NCOU =/ncou,

A number of layers in the thickness (ncou by defect = 3) and of sectors (nsec by defect = 16) on the circumference used for integrations in the elements PIPE [R3.08.06].

## 9.7 Operands

**PREC\_AIRE/PREC\_INERTIE**

PREC\_AIRE

=/precise,

PREC\_INERTIE

=/precise,

The use of the multifibre beams (POU\_D\_EM or POU\_D\_TGM) requires to provide additional information, compared to key words VALE and CARA, using the key words AFFE\_SECT and/or AFFE\_FIBRE [§12.3].

The objective is to check the coherence of the information (SURFACE and INERTIA) provided on the one hand by the key word BEAM and in addition by key words AFFE\_SECT and AFFE\_FIBRE. The criterion of error is based on the error relating and is compared either with the default value or to that given by the user via key words PREC\_AIRE and PREC\_INERTIE.

If the criterion is not satisfied a fatal error is generated.

*The relative error is calculated in the following way:*

$$\frac{SURFACE (BEAM) - (SURFACE (AFFE\_SECT) + AIRE (AFFE\_FIBRE))}{SURFACE (BEAM)} \leq PREC\_AIRE$$

$$\frac{INERTIA (BEAM) - (INERTIA (AFFE\_SECT) + INERTIE (AFFE\_FIBRE))}{INERTIA (BEAM)} \leq PREC\_INERTIE$$

Date:

31/01/06

Author (S):

**J-L. Key FLÉJOU**

:

*U4.42.01-II Page*

: 21/54

**Note:**

· *SURFACE (AFFE\_SECT) is calculated by making the sum of the surfaces of the elements defined in grid, under key word MAILLAGE\_SECT in operand AFFE\_SECT.*

· *SURFACE (AFFE\_SECT) is calculated by making the sum of the surfaces of fibres defined in the operand  
AFFE\_FIBRE.*

· *INERTIA (AFFE\_SECT) is calculated by making the sum of the  $s.d^2$  elements defined in grid, under key word MAILLAGE\_SECT in operand AFFE\_SECT. (S: represent surface of an element and D the distance between the centre of gravity of the element and the axis defined by*

*key word CARA\_AXE\_POUTRE under operand AFFE\_SECT).*

· *INERTIA (AFFE\_FIBRE) is calculated by making the sum of the  $s.d^2$  fibres defined in operand AFFE\_FIBRE. (S: represent the surface of a fibre and D the distance between fibre and the axis defined by key word CARA\_AXE\_POUTRE under operand AFFE\_FIBRE).*

**Note:**

*When the section is defined by a grid (key word MAILLAGE\_SECT under the operand AFFE\_SECT) the total calculation of the inertia of the surface whole of the elements does not hold account*

*inertia suitable for each element. It is thus necessary to define a sufficient number of fibre so that this error is weak and remains lower than PREC\_INERTIE.*

*For example a rectangular section cut out uniformly in the height in “N” elements conduit with the following errors, on the values of inertias:*

*Cutting*

2 3 4 5 6

*Inertia error*

**10 Word**

**key**

**ORIENTATION**

**10.1 Characteristics**

**easily affected**

*This key word makes it possible to affect the **orientations**:*

- of the principal axes of the cross sections of the elements of the beam type,*
- of the **discrete elements** assigned to nodes or meshes of the type PO11 (discrete elements nodal) or with meshes of the type SEG2 (discrete elements of connection).*

**Note:**

*There is always a local reference mark by defect attached to the elements of the BEAM type or DISCRETE*

*even if the operand ORIENTATION is not used. It corresponds to ANGL\_VRIL = 0 for elements attached to a mesh SEG2 (beams or discrete) and ANGL\_NAUT = (0. , 0. , 0.) for nodal discrete elements,*

*For the elements of the PIPE type, the key word ORIENTATION makes it possible to define a generating line*

*continue defining for each section the angular origin.*

### **10.3 Rules of use**

***One can assign successively to the same mesh or the same node, several values of orientation: the orientation finally taken is the composition of the orientations.***

#### **Example:**

**ORIENTATION= (  
\_F (  
CARA = ' ANGL\_NAUT', VALE= (1. , 1. , 1.), MESH = “P1”),  
\_F (  
CARA = ' ANGL\_VRIL', VALE = 45. , MESH = “M1”),  
\_F (  
CARA = ' ANGL\_VRIL', VALE = 90. , MESH = “m2”),  
)**

- to define the local reference mark associated with a mesh of the type PO11 or a node (discrete element), it is necessary to use either ANGL\_NAUT, or VECT\_X\_Y,*
- to define the local reference mark around the axis defined by a mesh SEG2 (beam or discrete), it is necessary to use either ANGL\_VRIL, or VECT\_Y,*
- to define a generating line on the elements pipe, it is necessary to use GENE\_TUYAU.*

## **11 Word**

**key**

**DEFI\_ARC**

### **11.1 Characteristics**

**easily affected**

*Allows to assign to curved beams (POU\_C\_T) (elements with 2 nodes) of the characteristics related to curve of the element (radius of curvature and orientation of the plan of the arc). Those can be defined in the choice by the key words: POIN\_TANG, CENTRE or (ORIE\_ARC and).*

### **11.2 Notice**

**The key words of DEFI\_ARC are used to define the geometrical characteristics (radius of curvature and**

**plan of the elbow) of the curved element of beam. The principal reference mark of inertia is not defined here, and must**

**to be given as for the right beams by the key word ORIENTATION (ANGL\_VRIL/VECT\_Y), in supposing that the element is right (segment NR NR**

**I**

**J).**

### **11.3 Syntax**

*11.8 Operand COEF\_FLEX, COEF\_FLEX\_XZ, COEF\_FLEX\_XY: coefficients of flexibility*

*COEF\_FLEX*

*= cflex*

*COEF\_FLEX\_XZ*

$= cflex_{xz}$   
 $COEF\_FLEX\_XY$   
 $= cflex_{xy}$

*For the modeling of the elbows of pipings the representation by elements of beam circular is insufficient to represent the flexibility of a thin hull. The coefficient of flexibility corrects the geometrical data (geometrical moments of inertia) in accordance with rules of construction. For example, rules  $RCC\_M$  lead, to make the calculation of rigidity of inflection with one geometrical moment of inertia:*

$I_y, Z$  (tube)

$I$   
 $=$   
 with  $cflex$   
 $y, Z$   
 $> .$   
 $I$   
 $cflex$

*A traditional value of  $cflex$ , for a piping thickness  $E$  and average radius  $R_{moy}$ , is*

$65$   
 $\cdot$   
 $I$   
 $E R$   
 given by:  
 $courb$   
 $cflex =$   
 with  
 $=$   
 $\cdot$   
 $2$

$R_{moy}$   
*This value can be calculated directly in the command file (see test  $FORMA01A$  for example).*

$I$  (tube)  
 $y$   
 $I_y = cflex_{xz}$

*If 2 coefficients are given, one obtains:*

$I$  (tube)  
 $I$   
 $Z$

$Z = cflex\_xy$

*By defect,  $cflex = cflex\_xz = cflex\_xy = 1$  (not of modification of geometrical inertias).*

### ***11.9 Operands INDI\_SIGM/INDI\_SIGM\_XZ/INDI\_SIGM\_XY: Index of intensification of the constraints***

***INDI\_SIGM***

***= isigm***

***INDI\_SIGM\_XZ***

***= isigm\_xz***

***INDI\_SIGM\_XY***

***= isigm\_xy***

***For the calculation of bending stresses in the curved elements of beams of section tubular, one can take account of a coefficient of intensification due to ovalization. The constraints are written then:***

***My. R***

***Mz. R***

***xx =***

***\*isigm or***

***\*isigm; with isigm 1.***

***Iy***

***Iz***

***If 2 indices are given, one a:***

***My. R***

***xx =***

***.isigm\_xz***

***Iy***

***Mz. R***

***or***

***xx =***

***.isigm\_xy***

***Iz***

*Key words used to define the section of the multifibre beams, (modelings POU\_D\_EM or POU\_D\_TGM) either using a grid (AFFE\_SECT) or fibre by fibre (AFFE\_FIBRE).*

## **12.2 Drank**

*Within the framework of a modeling of the multifibre type, there are two "levels" of modeling. It there with modeling known as "longitudinal" which will be represented by a beam (geometrical support SEG2)*

*and a modeling planes section (perpendicular to the SEG2). Key word AFFE\_SECT allows to associate a plane grid of section (read beforehand by operator LIRE\_MAILLAGE) an element beam. AFFE\_FIBRE makes it possible to describe the section in the form of specific surfaces.*

**Note:**

*It may be that in modeling section planes, several materials cohabit. By example, in a section concrete reinforced, there are at the same time concrete and reinforcements. In this case, operator CREA\_MAILLAGE allows to duplicate support SEG2 so that there is one material by support. (see for example test SSNL119 [V6.02.119]).*

**Caution:**

*The information given in AFFE\_SECT or AFFE\_FIBRE, makes it possible to calculate some integrated characteristics of the cross-sections (surface, moments static and quadratic). In spite of that, it is necessary to give coherent values for operands A, IY, IZ under the key word BEAM. A checking is carried out on the coherence of these sizes. If the relative error is too important (cf key words PREC\_AIRE, PREC\_INERTIE) a fatal error is emitted.*

## ***AFFE\_SECT and AFFE\_FIBRE***

***/AFFE\_SECT***

***/AFFE\_FIBRE***

***The entities of the grid of beams concerned and the sections define which are to them affected. Key word AFFE\_SECT makes it possible to affect a section defined by a plane grid (the elements of this grid are the sections of fibres) and key word AFFE\_FIBRE allows to affect a section where the fibres are defined by points.***

***The rule of overload applies between several occurrences of the key words factors AFFE\_SECT or AFFE\_FIBRE [U1.03.00].***

### ***12.3.1 Operands commun runs with AFFE\_SECT and AFFE\_FIBRE***

## **NAME**

*This operand makes it possible to define a name for the cross-section (8 characters). This name is pointed out*

*in the messages concerning this cross-section (see operand INFORMATION).*

*If NAME is not used under AFFE\_SECT, the name of the section (allotted automatically) is “SECT\_i” where I is the ième occurrence of AFFE\_SECT in the data file. The same if NAME is not used under AFFE\_FIBRE, the name of the automatic section is “PONCT\_j” where J is jème occurrence of AFFE\_FIBRE in the data file.*

## **12.3.2 Operands specific to AFFE\_SECT**

### **MAILLAGE\_SECT**

*Name of the plane “grid” which contains the “description of the section”.*

*By “grid”, one understands a whole of triangular meshes with 3 nodes and/or quadrilaterals with 4 nodes.*

*By “description of the section”, one understands part of this “grid” specified by one of operands TOUT\_SECT, MAILLE\_SECT or GROUP\_MA\_SECT. Each mesh represents section of a fibre.*

*/TOUT\_SECT*

*/MAILLE\_SECT*

*/GROUP\_MA\_SECT*

*Operands*

*Contents/Significance*

*TOUT\_SECT*

*The section is defined by the totality of the meshes of the grid defined under*

*MAILLAGE\_SECT*

*MAILLE\_SECT*

*The section is defined by a list of meshes*

*GROUP\_MA\_SECT*

*The section is defined by a list of groups of meshes*

*Note:*

- Since it is not used as support with finite elements, the “grid” does not have obligatorily to have a connectivity, it can be composed of a whole of juxtaposed meshes which touch or do not touch themselves.*
- All the meshes defined in the “description of the section” will have the same behavior, that of the finite element of beam to which they are affected (see remark in §1).*
- The co-ordinates y and Z of the plane grid of the section (y horizontal, Z vertical) are defined in a plan perpendicular to the axis of the beam. This axis is defined using the operand COOR\_AXE\_POUTRE. To define the angle of gimlet, i.e. the angle enters the axis there of the grid plan of the section and the axis Y of the element beam, it is necessary to use the key word ORIENTATION of operator AFFE\_CARA\_ELEM (see example).*

### *12.3.3 Operands specific to AFFE\_FIBRE*

*The cross-section of the element beam is defined by a whole of “specific” fibres.*

*CARA*

*Allows to specify if the third value given for each fibre is surface (by defect) or the diameter (see VALE).*

*VALE*

*Each fibre is described by a triplet of values: y, Z and valley. It is necessary to give them*

values according to this sequence, and there are as many triplets as of fibres.

- *Y* and *Z* are the co-ordinates of the center of fibre in a plan perpendicular to the axis of beam. The position of the axis of the beam can be modified thanks to the operand *COOR\_AXE\_POUTRE*. To give an angle of gimlet, the operand *ORIENTATION* should be used.
- *Val* is either the surface of a fibre, or the diameter of a cylindrical fibre.

**13 Word**

**key**

***DISCRETE and DISCRET\_2D***

**13.1 Characteristics**

***easily affected***

*These key words make it possible to assign directly to entities (meshs or nodes), which support elements of the type *DIS\_T*, *DIS\_TR* (*DISCRETE*) or *2D\_DIS\_T*, *2D\_DIS\_TR* (*DISCRET\_2D*), of matrices of **rigidity**, **mass** or **damping**.*

*On all the entities one can affect matrices corresponding to the degrees of freedom of translation (*T*) only or with the degrees of freedom of translation and rotation (*TR*). The matrices can be diagonals (*D*) or full. In this case, they are obligatorily symmetrical and one will only provide triangular higher, with a convention of classification of the terms imposed (see examples).*

*The matrices can be affected:*

- *with nodes or meshs of the types *POI1*; they are then known as nodal matrices (*NR*),*

· with meshes of the type *SEG2*; they are then known as matrices of connection (*L*).

In the event of assignment of matrices to meshes or nodes, the type of *DISCRETE* element must be affected, au préalable, with these meshes or these nodes by operator *AFFE\_MODELE* [U4.41.01].

**Note:**

*Two options  $M_{T_L}$  and  $M_{TR_L}$  do not correspond in general to an option of modeling having a mechanical significance. They are usable to only import in Aster of matrices of masses discretized on a mesh of the type SEG2 by another software. Indeed, one affect usually values of specific mass and inertia (mesh POI1) by  $M_{T_D_N}$  or  $M_{TR_D_N}$ .*

### **13.3.4 Operand *AMOR\_HYST***

***AMOR\_HYST = amor\_h,***

*Allows to assign to a discrete element a coefficient to build a matrix of rigidity complex (hysteretic modeling of damping) the built matrix is:*

(1+

)

**J**

***amor\_H K***

*where K is the  $K_*$  matrix whose values are provided in the same occurrence of the key word DISCRETE. The matrix of rigidity complexes will be actually built at the time of a call to CALC\_MATR\_ELEM [U4.61.01] with option AMOR\_HYST (see test SDLD313) and [R5.05.04].*

### **13.3.5 Operand *LOCATES***

***LOCATE***

***=/“LOCAL”,***

***/“TOTAL”,***

*By defect the values of the matrices provided for the discrete elements are used for*

*to express the corresponding quantities in the REFERENCE MARK = "TOTAL".*  
*If one wishes to define a particular reference mark in a node (or nets of type PO11) one will specify LOCATE = "LOCAL" by defining this reference mark by the key word ORIENTATION [§10].*  
*For a matrix defined on a mesh of the type SEG2 the operand LOCATES = "LOCAL" allows to refer to the local reference mark attached to the mesh (initial node, final node) supplemented if necessary of an angle of gimlet defined by the key word ORIENTATION [§10].*

## **15.2 Characteristics easily affected**

*This key word factor makes it possible to define the characteristics of rigidity of the finite element (quadrangle in four nodes) associated modeling “ASSE\_GRIL” (cf orders AFFE\_MODELE [U4.41.01]).*

*This modeling relates to the representation of the grids of the fuel assemblies, by one technique of homogenisation. It must be associated modeling "ASSE\_GRIL", allowing to model by homogenisation a network, periodical of beams, bathed in a fluid incompressible (cf [R4.07.05], cf key word factor POUTRE\_FLUI).*

### **15.3 Operand**

#### **GROUP\_MA/MESH**

*Place of employment of the elementary characteristics:*

- list meshes (key word NETS),*
- list of groups of meshes (key word GROUP\_MA).*

### **15.4 Operand**

#### **ANGL\_REP**

*ANGL\_REP = (,)*

*A reference mark (L, T, NR) is associated each mesh. The direction L is the direction perpendicular to the plan means of the mesh.*

*The angles in degree (,) make it possible to define compared to the reference mark of reference the vector to project on the average level of the mesh and which will indicate the direction T (as for the key word HULL, operand ANGL\_REP [Figure 8.3.3-c]).*

### **15.5 Operand**

#### **PAS\_T/PAS\_N/COEF\_ECHELLE**

*These operands define the geometrical characteristics of the characteristic periodic cell grid. COEF\_ECHELLE defines the coefficient of homothety making it possible to transform the cell periodical real in the basic periodic cell with which the homogenized coefficients are calculated.*

*PAS\_T and PAS\_N define dimensions of the rectangular basic cell along the axes T, NR local reference mark.*

### **15.6 Operands**

#### **CARA/VALE**

*These operands make it possible to define all rigidities of the springs associated with this modeling (HI-75/96/074/0).*

## **18.2 Characteristics**

### **easily affected**

*This functionality corresponds to a methodology used by the SEPTEN to determine them characteristics of discrete elements (springs of translation and/or rotation) to apply to the nodes of a foundation raft starting from results obtained by the code PARASOL.*

*One must affect modeling "DIS\_TR" or "DIS\_T" on the group of nodes which make it up to erase.*

*The meshes which make the foundation raft (pertaining to the l\_gma groups) carry when to them one modeling of plate (DKT, DST) cf test SDLS108 [V2.03.108] or a modeling of face of 3D.*

## **18.3 Description of the operands**

- **GROUP\_MA**: list groups of meshes which make the foundation raft.
- **GROUP\_MA\_POII**: list groups of points including/understanding the nodes of the groups of meshes surface defined by **GROUP\_MA**. That makes it possible to declare the nodes of a foundation defined by surface meshes like specific meshes **POII** in order to affect the characteristics to them **RIGI\_PARASOL** what makes it possible to affect materials or behaviors to them for the use of a nonlinear operator. If it is not present, the nodes are regarded as late meshes for a strictly linear study for example.
- **FONC\_GROUP/COEF\_GROUP**: list real functions or coefficients. There are as many arguments in this list that there are groups of meshes which make the foundation raft (definite under the key word **GROUP\_MA**). The functions must have as a X-coordinate the distance to the centre of gravity (key word defined by **GROUP\_NO\_CENTRE/NOEUD\_CENTRE/COOR\_CENTRE**).
- The total stiffnesses of ground, resulting from the code **PARASOL** are provided by the user using key words **CARA** and **VALE** as for the discrete elements. One can also select nature reference mark (total or local) in which one defines the characteristics of the springs (key word **LOCATE**). Stiffnesses or the depreciation only defined in translation can also to be distributed (**K\_T\_D\_N** or **A\_T\_D\_N**, not stiffness in rotation), in this case it is only necessary to give 3 values behind **VALE** = (kx, ky, kz).
- To define the center of the foundation raft (calculated by the code **PARASOL**), one can is to give them co-ordinates (three realities given behind key word **COOR\_CENTRE**), is to give the name of a node

*grid (for more facility, one accepts also the name of a group of nodes but this one must contain that only one node: key word *GROUP\_NO\_CENTRE* or *NOEUD\_CENTRE*).*

*· *GROUP\_MA\_POII* makes it possible to specify a group of specific meshes containing the nodes of groups of surface meshes (to erase) definite under *GROUP\_MA*. On these nodes of foundation, one will be able to affect various behaviors materials for the use by an operator not linear.*

#### ***18.4 Principle of determination of the characteristics of the elements discrete [R4.05.01]***

*One represents the foundation raft by a whole of surface elements of centre of gravity *O*. Using code *PARASOL*, one obtains 6 total sizes which characterize the coupling ground-foundation raft: three stiffnesses*

*of *Kx* translation, *Ky*, *Kz* and three stiffnesses of rotation *Krx*, *Kry*, *Krz*.*

*In each node of the grid of the foundation raft, Code\_Aster seeks the characteristics in stiffness of one discrete element of type *K\_TR\_D\_N* (*kx*, *ky*, *kz*, *krx*, *kry*, *krz*) cf [R4.05.01].*

*To determine the stiffnesses of translation, one forces that they are proportional to surface represented by the node and with a function of distribution depending on the distance to the centre of gravity*

*foundation raft. That is to say *S (P)* the surface attached to the node *P* and *F (R)* the function of distribution where *R* is the distance node *P* with the node *O*.*

*For the stiffnesses of rotation, one distributes the remainder (what remains after having removed the contributions had with the translations) in the same way that translations.*

*If one calculates the efforts and the moments resulting at the point *O* due to the distribution from the springs in*

*each node of the grid of the foundation raft and if one identifies them with the values obtained by PARASOL, one obtains the following formulas:*

$$K = K/S$$

*X*

*X*

$$(p) F (COp); K (P) = K S$$

Document: U4.42.02***

***Macro-order MACR\_CARA\_POUTRE***

***1 Goal***

***To calculate the characteristics of a cross section of beam starting from a grid 2D of section.***

***It makes it possible to build a table of values, usable by order AFFE\_CARA\_ELEM [U4.42.01] to assign characteristics of cross-sections to all the finite elements of beam (modelings POU\_D\_E, POU\_D\_T, POU\_C\_T, POU\_D\_TG, POU\_D\_EM, POU\_D\_TGM) or of bar (modeling BARS) unspecified section.***

***The characteristics necessary are defined in the note of reference [R3.08.03]. It is:***

***.  
the geometrical characteristics (which can be calculated on the complete grid, half grid with symmetry compared to X or with Y, quarter of grid with two symmetries by report/ratio with X and Y),***

***.  
characteristics of torsion: ray of torsion, constant of rigidity in torsion, position and eccentricity of the center of torsion for the coupling inflection-torsion,***

***.  
characteristics of shearing for the models with deformations of shearing action,***

***.  
characteristics of warping for the models of “open” torsion of the sections nonsymmetrical.***

***Product a table containing the characteristics of the section. Values contained in this table can be introduced directly (via python) into order AFFE\_CARA\_ELEM for a calculation of the beam type.***

### *3 Operands*

#### *3.1 Operand*

*UNITE\_MAILLAGE*

*UNITE\_MAILLAGE*

*Logical number of unit for the reading of the grid 2D of the section of beam which one will calculate characteristics with the format Aster: i.e. a grid which can be read by LIRE\_MAILLAGE.*

*Note:*

*If one must call several upon MACR\_CARA\_POUTRE in the same command file on the same grid or of the different grids UNITE\_MAILLAGE should then be changed.*

#### *3.2 Operands*

***SYME\_X/SYME\_Y******/ SYME\_X***

***Specify that the grid provided by the user corresponds to a half grid. The calculation of characteristics of the cross-section takes account of a symmetry compared to  $X = 0$ .***

***/ SYME\_Y***

***Specify that the grid provided by the user corresponds to a half grid. The calculation of characteristics of the cross-section takes account of a symmetry compared to  $Y = 0$ .***

***The simultaneous use of the two options makes it possible to provide only one quarter of the grid.***

***The properties of symmetry are used to accelerate the calculation of the characteristics geometrical.***

***Note:***

***Key words SYME\_X and SYME\_Y are used only for the calculation of the characteristics geometrical. Mechanical characteristics (constant of torsion, constant of warping, coefficients of shearing) do not hold account of it. To calculate them, it is necessary thus to net the section in entirety. This is why SYME\_X and SYME\_Y cannot be informed simultaneously with GROUP\_MA\_BORD.***

**3.3*****Calculation of the mechanical characteristics***

***GROUP\_MA\_BORD = lgb***

***lgb indicates one (or several) group of meshes (SEG2 or SEG3) describing the contour (closed) of the section with a grid. It is the presence of this key word which involves the calculation of the characteristics mechanics of the section (cf [U4.42.01] AFFE\_CARA\_ELEM, key word BEAM).***

***GROUP\_MA\_INTE = lgi***

***lgi indicates one or more groups of meshes describing contours of possible holes. This data is used for calculation of the constant of torsion.***

***GROUP\_MA = lgm***

***lgm corresponds to a list of groups of meshes for which the calculation of the characteristics must to be carried out independently. This functionality makes it possible in particular to seek them characteristics of beam equivalent to several disjointed sections. If one wishes the calculation of***

*mechanical characteristics for each group of mesh, it is then necessary to give a group of meshes of edge by section (using key word GROUP\_MA\_BORD). The lists lgb and lgm must then to correspond.*

#### **4.2.2 Characteristics**

**“mechanical”**

*These characteristics are provided in the table for all the grid and each group of mesh list lgm.*

##### **4.2.2.1 Characteristics of torsion**

- *constant of torsion: CT*

*The resolution of a stationary thermal problem of unknown factor phi makes it possible to determine constant of torsion and stresses shear.*

- *ray of torsion: RT*

*The ray of torsion “RT” can vary along external contour; indeed, for a section unspecified, shearings due to torsion vary on the edge. One chooses to take the value of Rt leading to shearings maximum on the external edge, i.e. the maximum value of Rt (in absolute value) on external contour. Moreover, if the section is alveolate, there are several “several rays of torsion”:  $Rt = 2 \cdot A(K) / L(K)$  (or  $A(K)$  represents the surface of the cell K and L(K) sound perimeter).*

*If one is satisfied to seek the maximum value of shearing, it is necessary to take the maximum of Rt values obtained on the external edge and the cells.*

- *Position of the center of torsion (point C) in reference mark GXY: PCTX and PCTY. One deduces some*

*the eccentricity of the center of torsion (component of CG in the principal reference mark of Gyz inertia): EY and*

*EZ.*

- *Constante of warping (usable for modelings POU\_D\_TG and POU\_D\_TGM with 7 degrees of freedom): JG*

##### **4.2.2.2 Characteristics of shearing**

*The coefficients of shearing are given, in the principal reference mark of Gyz inertia, in the form of report/ratio (> 1) of the total surface to the actually sheared surface: AY and AZ*

#### **4.3 Assignment of the sizes in AFFE\_CARA\_ELEM**

*The values contained in this table can be in order AFFE\_CARA\_ELEM for one calculation of the beam type.*

*In AFFE\_CARA\_ELEM, the characteristics are to be provided in the principal reference mark of inertia (G, y, Z).*

*Quantities required (IY, IZ.) correspond to those calculated in the principal reference mark of inertia defined starting from G, X, Y (IY\_PRIN\_G, IZ\_PRIN...).*

*It is thus necessary to take guard with directing well the local reference mark of the elements of beam (key word*

*ORIENTATION of AFFE\_CARA\_ELEM) in order to affect the quantities correctly.*

*It is possible to directly provide (via variables python) the characteristics of the sections (general) resulting from a calculation with MACR\_CARA\_POUTRE. This is implemented in the test SSSL107F.*

***3 Operands***

***3.1 Operand***

## **MODEL**

**MODEL = model**

**Concept produced by operator AFFE\_MODELE [U4.41.01] allowing to define the types finite elements assigned to the meshes of the grid.**

### **3.2 Operand**

**CHAM\_MATER**

**CHAM\_MATER = chmat**

**Concept produced by operator AFFE\_MATERIAU [U4.43.02] allowing to affect materials with the meshes of the grid.**

### **3.3 Operand**

**CARA\_ELEM**

**CARA\_ELEM = caelem**

**Concept produced by operator AFFE\_CARA\_ELEM [U4.42.01] allowing to affect mechanical and geometrical characteristics with the elements of the studied structure.**

### **3.4 Operand**

**GROUP\_MA\_BETON**

**GROUP\_MA\_BETON = l\_grmabe**

**Name of (or of) the group (S) of meshes of the grid representing the structure concrete. One defines thus**

**precisely the locus of projection of the cables, preliminary stage to the determination relations kinematics between the DDL of the nodes of the cables and the DDL of the nodes of structure concrete.**

**Note: the groups of concrete meshes can have elastoplastic properties different but the characteristics specific to BPEL\_BETON () must be identical.**

### **3.5 Key word**

**DEFI\_CABLE**

**DEFI\_CABLE**

**Key word factor allowing the definition of a cable by designation of the topological entities of grid which represent it. The multiple occurrences are authorized, in order to be able to define several cables.**

***/GROUP\_MA = grmaca***

***Name of the group of meshes of the grid representing the cable.***

***/***

***NET***

***=***

***l\_maca***

***List meshes of the grid representing the cable. Functionality incompatible with key word CONE (to use GROUP\_MA).***

***/NOEUD\_ANCRAGE = l\_noa***

***List nodes defining anchorings of the cable, i.e the ends. This list must to comprise 2 arguments, neither more nor less.***

***/***

***GROUPE\_NOEUD\_ANCRAGE***

***=***

***l\_gnoa***

***List groups of nodes defining anchorings. The cardinal of this list must be less than or equal to 2. In each group of node, one will not retain like anchoring that the first node of the group.***

### **3.6 Operand**

#### **TYPE\_ANCRAGE**

**TYPE\_ANCRAGE = l\_tya**

*List arguments of the text type characterizing anchorings of the cable: “ACTIVE” or “PASSIVE” (only licit arguments). This list must comprise 2 arguments, neither more nor less, and must be ordinate compared to the list of the nodes defining anchorings (operand NOEUD\_ANCRAGE above). It should be noted that if several cables are defined in DEFI\_CABLE then the first argument of TYPE\_ANCRAGE applies to all the first nodes which define anchorings. Idem for the second argument.*

#### **Note:**

*The operator reconstitutes the driving related way of the first to the second anchoring of the cable by traversing the meshes which represent it. Nonthe existence of a related way enters two anchorings causes a program stop in fatal error.  
Active anchorings are those where an initial tension is applied.*

### **3.7 Operand**

#### **TENSION\_INIT**

**TENSION\_INIT = f0**

*Value of the initial force applied to active anchorings of the cables.  
This value must be positive.*

### **3.8 Operand**

#### **RECU\_L\_ANCRAGE**

**RECU\_L\_ANCRAGE = delta**

*Value of the retreat to active anchorings of the cables.  
This value must be positive.*

### **3.9 Key word**

#### **CONE**

#### **CONE**

*This key word factor makes it possible to define a geometrical volume around anchorings, and to affect, in exit of AFFE\_CHAR\_MECA key word RELA\_CINE\_BP, with all the nodes (concrete and cable) contained*

*in this volume, a kinematic relation of type LIAISON\_SOLIDE (rigid body). The definition this volume makes it possible to attenuate the constraints which the tensions at the ends generate of cables on the concrete. In reality, this phenomenon is avoided thanks to the installation of a cone of diffusion of constraint (material harder than the concrete) which distributes the force of prestressed on a great surface of the concrete. In practice, the practically right cone being, one defined a volume cylindrical:*

*ray*

*length*

*Real situation*

*Modeling EF*

*Author (S):*

**S. MICHEL-PONNELLE, A. ASSIRE** Key

:

*U4.42.04-C Page*

: 5/8

*It should be noted that several rigid cones and thus several blocks are defined if the key word **PRESENT** two “YES” (a block per end of the cable contains) and/or if several cables are defined under **DEFI\_CABLE**.*

**Note:**

*In practice, the cylinder is defined by order **DEFI\_GROUP** option **TUNNEL**. methodology of extraction of the nodes contained in the cone is described in the document **U4.22.01** (order **DEFI\_GROUP**).*

*/RAY = ray*

*Ray of the cone.*

*/*

**LENGTH**

=

*length*

*Length of the cone, with the curvilinear direction X-coordinate on the cable. One defines the cone as a succession of cylinder while stopping when the overall length of the cylinders is equalize with the parameter length.*

*/PRESENT = l\_pre*

*This list must comprise 2 arguments, neither more nor less, and must be ordered in glance list of the nodes defining anchorings (operand **NOEUD\_ANCRAGE** above). The only valid arguments are “YES” or “NOT”, and make it possible to define the cone on*

two anchorings (  
**PRESENT** = (“YES”, “YES”,)  
 ), on the first anchoring  
 (**PRESENT** = (“YES”, “NOT”,)) or on the second anchoring  
 (**PRESENT** = (“NOT”, “YES”,)). It should be noted that if several cables are defined in  
**DEFI\_CABLE** then the first argument of **PRESENT** applies to all the first  
 nodes which define anchorings. Idem for the second argument.

### **3.10 Key word GRID**

**GRID**

Name of the grid on which one works. This concept is obligatory since the key word **CONE**  
 is well informed. It will be removed in version 8.

### **3.11 Key word RELIEVING**

**RELIEVING**

Key word factor allowing the definition of a parameter for the taking into account of the losses of  
 tension by relieving of steel. This key word factor being optional, by defect losses of  
 tension by relieving of steel are not taken into account.

$R_J = r_j$

Value of the adimensional function  $R(J)$  characterizing the evolution of the relieving of steel  
 in time; for example the BPEL 91 recommends:

$J$   
 $R(J) =$   
 with  $J$  in days  
 $J + 9 \times r_m$

surface of the concrete section  
 and  $r_m =$   
 average radius  
 perimeter of the concrete section

This value must be positive or null.

$J$  corresponds to the date (in days) for which one wants to estimate the state of stress in  
 structure. For the case where, in the structural analysis, the bars would be modelled with one  
 behavior of the type creep, one should not inform this key word in **DEFI\_CABLE\_BP**.

*TITRATE = l\_titr*

*List arguments of the text type defining a title attached to the concept [cabl\_precont].*

**4**

***Theoretical complement: estimate of the losses of tension in a cable of prestressed according to the regulations of BPEL***

*The evolution of the tension (in Newton) along a cable of prestressing is calculated by using them relations prescribed by the BPEL. These relations are as follows:*

**4.1**

***Evolution of the tension in the vicinity of anchoring***

~

~

5

*F (S)*

~

$$F(S) = F(S) - X$$

$$\mu$$

$$flu \times F_0 + xret \times F_0 + R(J) \times$$

$$\times$$

$$-$$

$$\times F(S)$$

$$0$$

1000

100

S

 $\times y$  has

where  $S$  indicates the curvilinear  $X$ -coordinate along the cable. Parameters introduced into this expression are:

.  
 $F_0$   
 initial tension (NR);

.  
 $X_{flu}$   
 standard rate of loss of tension by creep of the concrete, compared to the tension initial;

.  
 $xret$   
 standard rate of loss of tension by shrinking of the concrete, compared to the tension initial;

.  
 1000 relieving of steel at 1000 hours, expressed in %;

.  
 $I_{ts}$   
 surface of the cross-section of the cable defined in  $AFFE\_CARA\_ELEM$ ;

.

$y$   
stress ultimate elastic steel;

$\mu_0$   
adimensional coefficient of relieving of prestressed steel.

$R(J)$  is an adimensional function characterizing the evolution of relieving in time:

$J$   
surface of the concrete section  
 $R(J) =$   
with  $J$  in days and  $R =$   
average radius  
 $J + 9 \times R$   
 $m$   
 $m$   
perimeter of the concrete section

The function  $R(J)$  depend on the geometry of the structure, the value used is defined in operator  $DEFI\_CABLE\_BP$ .

$F(S)$  is the evolution of the tension in the vicinity of anchoring after taking into account of the loss by retreat of anchoring and the losses by contact between the cable and the concrete.

$F(S)$   
2  
is defined by the relation:  $FC(S) \times F(S) = [FC(D)]$

$FC(S)$  indicates the evolution of the tension along the cable after taking into account of the losses by contact between the cable and the concrete:  $FC(S) = F_0 \exp(p - F - S)$   
indicate the cumulated angular deviation and the parameters introduced into the expression of  $FC(S)$  are:

$F$  coefficient of friction of the cable on the partly curved concrete, in rad1;  
coefficient of friction per unit of length.

### **3 Operands**

#### **3.1 Operands**

**MODEL/CHAM\_MATER/CARA\_ELEM**

**MODEL = Mo**

*Name of the model whose elements are the subject of mechanical calculation.*

**CHAM\_MATER** = *chmat*

*Name of the affected material field on the grid. Attention, all meshes of the model must be associated a material.*

**CARA\_ELEM** = *carac*

*Name of the characteristics of the elements of hull, beam, pipe, bars, discrete cable and elements affected on the model Mo.*

### **3.2 Word**

*key*

**EXCIT**

**EXCIT** =

*This key word factor makes it possible to describe a load with each occurrence. It is necessary to provide them*

*boundary conditions for the structure, possibly of the instantaneous loadings like*

*gravity as well as the connections kinematics related to the cables having already been put in tension by a preceding call to CALC\_PRECONT. To in no case, one should not include the loading of the cable that one wants to put in tension by the call to this macro-order.*

#### **3.2.1 Operands**

**CHARGE**

**CHARGE** = *chi*

*CH is the mechanical loading specified with the ième occurrence of*

*I*

**EXCIT**.

### **3.3 Word**

*key*

**COMP\_INCR**

*The syntax of this key word common to order STAT\_NON\_LINE is described in the document [U4.51.03].*

### **3.4 Word**

*key*

**INCREMENT**

**INCREMENT** =

*Defines the intervals of time taken in the incremental method.*

### **3.4.1 Operands**

#### ***LIST\_INST***

*LIST\_INST = litps*

*The moments of calculations are those defined in the concept litps by the operator DEFILIST\_REEL [U4.34.01]. This list must be ordered in a chronological way (increasing).*

#### **Note:**

*Even if calculation is carried out with several steps of time, only the last step of time is stored in the concept result.*

*During the process of setting in tension of the cables, moments are generated automatically in addition to those provided by the user. It is thus completely normal to see to appear in the file of message of calculations with STAT\_NON\_LINE at moments that the user did not specify. These moments are not stored in the concept result.*

*U4.42.05-A Page*

*: 5/10*

### **3.4.2 Operands**

#### ***INST\_INIT/INST\_FIN***

*INST\_INIT*

= *instini*

*The initial moment of the calculation (which thus (Re) is not calculated) must be indicated by its value.*

*If this initial moment is not recomputed, the defect is calculated in the following way:*

.  
*if an initial state is specified (operand ETAT\_INIT) and if it definite one moment corresponding (by EVOL\_NOLI or INST\_ETAT\_INIT) then the initial moment is that defined by the initial state,*

.  
*if there is no initial state (operand ETAT\_INIT) or that it does not define a moment corresponding (the fields are given in ETAT\_INIT without specifying INST\_ETAT\_INIT), then one takes the first moment of the list of moments litps (NUME\_INST\_INIT =0).*

*INST\_FIN*

=

*instfin*

*The final moment (last calculated step) is indicated same manner as the initial moment, except that it is not possible to refer to the moment of the initial state.*

### **3.4.3 Operand PRECISION**

*PRECISION*

=

*prec (cf [U4.71.00])*

### **3.4.4 Operand SUBD\_PAS/SUBD\_PAS\_MINI/COEF\_SUBD\_PAS\_1**

*SUBD\_PAS = subpas,*

*SUBD\_PAS\_MINI = submini,*

*COEF\_SUBD\_PAS\_1 = coefsub,*

*Allows to carry out an automatic recutting of the step of time when the algorithm of Newton do not converge.*

*The step of time is redécoupé in subpas under step. By defect there is no recutting (SUBD\_PAS = 1). The automatic subdivision stops when the new steps created are more*

*small that SUBD\_PAS\_MINI. The new steps created are of identical size, except the first who is equal to this size multiplied by COEF\_SUBD\_PAS\_1 (by defect 1). This allows best to take into account the problems of discharge of the structure (change of tangent matrix) without using the elastic matrix (PREDICTION = ' ELASTIQUE' or MATRIX = "ELASTIC" under the operand NEWTON).*

### **3.5 Word**

*key*

**CABLE\_BP**

$CABLE\_BP = l\_cabl\_pr$

*It is a question here of providing a list of the concepts of the cabl\_precont type produced by the operator DEFI\_CABLE\_BP [U4.42.04]. All the cables concerned will be tended at the end of this calculation.*

### **3.6 Word**

*key*

**CABLE\_BP\_INACTIF**

$CABLE\_BP\_INACTIF = l\_cabl\_pr$

*It is a question here of providing a list of the concepts of the cabl\_precont type produced by the operator DEFI\_CABLE\_BP [U4.42.04]. The macro-order is given the responsibility to generate the connections kinematics related to these inactive cables, and does not take into account the rigidity of these cables.*

.

*Preliminary calculation before setting in tension of the cables (optional)*

*It is a question here of taking into account the loadings which apply to the structure before the setting in tension of the cables. Not to take into account the rigidity of the cables, and not to introduce one loading on the cables, it is necessary to carry out calculation is on a model not containing the cables*

*maybe in their affecting a law of behavior WITHOUT, which imposes that the constraint remains null in these elements.*

```
RES1 = STAT_NON_LINE (MODELE=MO,  
CHAM_MATER=CMAT,  
CARA_ELEM=CE,  
COMP_INCR= (_F (RELATION = "ELAS"),  
_F (RELATION = "WITHOUT",

***1 Goal***

*To define the behavior of a material or the parameters associated with tiredness, the damage, or with simplified methods.*

*The allowed laws of behavior currently by this operator relate to the following fields:*

*Linear mechanics and Thermics or not, Metallurgical for the modeling of steels, Hydration and Drying for the concretes, Fluid for accoustics, Thermo-Hydro-Mechanics for the modeling of the porous environments saturated with thermomechanical coupled and Soil mechanics.*

*If necessary, the same material can be defined at the time of a call to **DEFI\_MATERIAU** with several behaviors, such as rubber band, thermics,...*

*Product a Structure of data of the type **MATER**.*

)  
**Note:**

*For the majority of the behaviors, it is possible to define constant characteristics or many characteristics depending on one or two variables. We chose to gather them two key words factors, single-ended spanner words being identical in both cases, only their arguments are characterized by the type of associated concept.*

*In the syntax of each behavior, one will adopt following convention to indicate it or the variables of which can depend the concepts of the function type.*

***ALPHA/TEMP\_DEF\_ALPHA/PRECISION***

***ALPHA =***

***[function \*\*]***

***Isotropic thermal dilation coefficient.***

***The thermal dilation coefficient is an average dilation coefficient which can depend on the temperature T.***

***The values of the dilation coefficients are determined by tests of dilatometry which have place at the ambient temperature (0°C or more generally 20°C).***

***So one in general has the values of the dilation coefficient defined compared to 20°C (temperature to which one supposes the null thermal deformation).***

*Certain studies require to take a temperature of reference different from ambient temperature (null thermal deformation for another temperature that ambient temperature). It is then necessary to carry out a change of reference mark in the calculation of thermal deformation [R4.08.01].*

**TEMP\_DEF\_ALPHA = Tdef**  
**[R]**

*It is the value of the temperature to which the values of the thermal dilation coefficient have summer determined, and were well informed under the key word ALPHA.*

*This key word becomes obligatory as soon as ALPHA was informed.*

*The calculation of the thermal deformation is done by the formula [R4.08.01]:*

*(T) T - T*  
*- T*  
*T*  
*- T*  
*HT*  
*(def) (ref.) (ref. def)*  
*(T)*  
*= \$ (T) (T - Re*  
*T F) with \$ (T) =*  
*T - ref.*  
*T*

*and*  
*HT (ref.*  
*T) = 0*

**PRECISION: /prec**

/

1.

**[DEFECT]**

*This key word is used when key word TEMP\_DEF\_ALPHA is specified.*

*It is a reality which indicates with which precision a temperature  $T_i$  (of the list of the temperatures being used for the definition of  $(T_i)$ ) is close to the temperature of reference  $T$ ,  $i=$ ,*

***1 NR***

**Key J.P. LEFEBVRE**

**:**

**U4.43.01-II Page**

**: 25/148**

### **3.5.2 Operands of elasticity**

**The reader will be able to refer to following documentations:**

**[U4.42.03] DEF1\_COQU\_MULT**

**[U4.42.01] AFFE\_CARA\_ELEM**

**to define the reference mark of orthotropism (*L, T, NR*) related to the elements.**

**$E_L$  = *ygl* longitudinal Modulus Young.**

***NR***

***T***

***L***

***L, T* and *NR*: directions of orthotropism  
longitudinal, transverse and normal**

**$E_T$  = *ygt* transverse Modulus Young.**

*$E_N$  = ygn normal Modulus Young.*

*$GL_T$  = glt Modulus of rigidity in plan LT.*

*$G_{TN}$  = gtn Modulus of rigidity in plan TN.*

*$G_{LN}$  = gln Modulus of rigidity in plan LN.*

*Note:*

*For the hulls, the transverse moduli of rigidity are not obligatory; in it case, one calculates in thin hull by assigning an infinite rigidity to transverse shearing (DST elements, DSQ and Q4G).*

*$NU_{LT}$  = nult Poisson's ratio in plan LT.*

*Important remarks:*

*ygt  
nult is not equal to nutl. In fact, one with the relation:  $nult =$   
nult  
\**

*ygl  
nult must be interpreted in the following way:*

*if one exerts a traction according to the axis L giving place to a deformation according to this axis equalizes with  
L*

*L  
L =  
, there is a deformation according to the axis T equalizes with:  $T = - nult^*$*

*ygl  
ygl*

*The various moduli of elasticity  $E_L$ ,  $G_{LN}$  and  $NU_{LN}$  cannot be selected of unspecified way: physically, it is necessary always that a nonnull deformation causes one strictly positive deformation energy. That results in the fact that the matrix of Hooke must be definite positive. Operator  $DEFI\_MATERIAU$  calculates the eigenvalues of this matrix and emits an alarm if this property is not checked.  
For the models 2D, like the user its  $MODELING$  ( $D\_PLAN$  did not choose yet,*

*C\_PLAN,...), one checks the positivity of the matrix in the various cases of figure.*

*ygn*

*The various moduli of elasticity  $E_L$ ,  $G_{LN}$  and  $NU_{LN}$  cannot be selected of unspecified way: physically, it is necessary always that a nonnull deformation causes one strictly positive deformation energy. That results in the fact that the matrix of Hooke must be definite positive. Operator  $DEFI\_MATERIAU$  calculates the eigenvalues of this matrix and emits an alarm if this property is not checked. For the models 2D, like the user its  $MODELING$  ( $D\_PLAN$  did not choose yet,  $C\_PLAN$ ,...), one checks the positivity of the matrix in the various cases of figure.*

2

0 0 2

*For the orthotropic hulls whose moduli of elasticity are obtained by a method of homogenisation, it is not possible in the case general to find a Young modulus equivalent  $E_{eq}$ , and an equivalent thickness  $h_{eq}$  to find the preceding expressions.*

*The matrices of rigidity are thus given directly in the form:*

*Membrane:*

*Inflection:*

*Shearing:*

$C_{1111} \ C_{1122} \ 0$

$D_{1111} \ D_{1122} \ 0$

$G_{11} \ 0$

$C = C_{1122} \ C_{2222} \ 0$

$D = D_{1122} \ D_{2222} \ 0$

$G = 0$

$G_{22}$

0

0

$C_{1212}$

0

0

$D_{1212}$

*On the other hand, one limits oneself to the cases where the thermal dilation coefficient is homogeneous isotropic.*

*These coefficients are to be provided in the local reference mark of the element. It is defined by key word ANGL\_REP*

*AFFE\_CARA\_ELEM [U4.42.01].*

*Notice concerning the taking into account of transverse shearing following the models of hulls:*

*If one wishes to use ELAS\_COQUE with transverse shearing it is necessarily necessary to employ DST modeling. If one uses modeling DKT, transverse shearing will not be taken into account, some are the values of  $G_{11}$  and  $G_{22}$ . Correspondence for one isotropic material is as follows:*

.

*The material ELAS\_COQUE, DST modeling with  $CISA_* = 5/12 * (Eh/(1+\nu))$  is equivalent with the material ELAS, DST modeling.*

•  
*The material ELAS\_COQUE, DST modeling with  $CISA_* = 5/12 * (Eh/(1+\nu)) * N$ , where NR is one great number (for example 105), is equivalent to the material ELAS, modeling DKT.*

•  
*The material ELAS\_COQUE, modeling DKT is equivalent to the material ELAS, modeling DKT.*

*Matrices of behavior connecting the efforts generalized to the deformations for the elements of plate and fascinating account the terms of coupling are in the following way defined:*

*Membrane:*

*Inflection:*

*Membrane - inflection:*

*H1111 H1122 H1112*

*A1111 A1122*

*A1112*

*B1111 B1122 B1112*

*The curve of work hardening used in  
E  
models of behavior is then:  
T*

*sigm  
R (p) = + H  
y  
p  
E. AND  
E  
with H =*

*E - AND  
I  
It is thus necessary to respect: E  
E  
T <*

*The Young modulus E is to be specified by key words ELAS or ELAS\_FO.*

**4.3**  
*Key words factor PRAGER/PRAGER\_FO*

*When the way of loading is not monotonous any more, work hardenings isotropic and kinematic are not more equivalent. In particular, one can expect to have simultaneously a kinematic share and one isotropic share. If one seeks to precisely describe the effects of a cyclic loading, it is desirable to adopt modelings sophisticated (but easy to use) such as the model of Taheri, for example, cf [R5.03.05]. On the other hand, for less complex ways of loading, one can wish to include only one linear kinematic work hardening, all nonthe linearities of work hardening being carried by the isotropic term. That makes it possible to follow a curve precisely of traction, while representing nevertheless phenomena such as the Bauschinger effect [R5.03.16].*

*The characteristics of work hardening are then given by a traction diagram and a constant, said of Prager, for the term of kinematic work hardening linear. Key word PRAGER makes it possible to define the constant of PRAGER, used in the models with mixed work hardening (kinematic linear compound with isotropic) VMIS\_ECMI\_LINE or VMIS\_ECMI\_TRAC.*

### 4.3.1 Syntax

*ecrod*  
*[R]*,

)

### *5.3.2 Operand ALPHA*

*Constant of coupling between the evolution of the damage of traction and that of the damage of compression. It must be taken between 0 and 1, rather near to 1. The value by defect is 0.9.*

### *5.3.3 Operands K0/K1/K2*

*K0 = k0*  
*Constant part of the function threshold. Allows to gauge the height of the peak in traction.*

*K1 = k1*  
*Parameter of the function threshold allowing to increase the threshold in compression.*

*K2 = k2*  
*Parameter of control of the shape of the envelope of rupture for biaxial tests. The value by defect is 7.104.*

### *5.3.4 Operands ECROB/ECROD*

*ECROB = ecrob*

*Term of blocked energy (equivalent to an energy of work hardening) relating to the evolution of*

*the damage of traction. Allows to control the shape of the peak in traction.*

***ECROD = ecrod***

*Term of blocked energy (equivalent to an energy of work hardening) relating to the evolution of the damage of compression. Allows to control the shape of the peak in compression.*

*The Young modulus E and the Poisson's ratio are to be specified by key words ELAS or ELAS\_FO.*

*In the case of a nonlocal calculation with formulation GRAD\_EPSI, the characteristic length is to specify behind key word NON\_LOCAL.*

#### **5.4.2 Operands**

**LONG\_CARA/COEF\_RIGI\_MINI**

**LONG\_CARA:**

*Determine the length characteristic or scale length internal to material.*

**COEF\_RIGI\_MINI**

*With as for him an algorithmic role since it fixes, for the models of damage which degrades rigidity of material, the proportion of initial rigidity IE of the Young modulus defines under ELAS (0,1% for example) in on this side which one stops the damage mechanism: this residual rigidity allows to preserve the character posed well of the elastic problem.*

#### **5.5**

**Key word factor RUPT\_FRAG/RUPT\_FRAG\_FO**

*The theory of the rupture of Frankfurt and Marigo makes it possible to model the appearance and the propagation of cracks in a fragile springy medium, to see [R7.02.11]. It is based on the criterion of Griffith who compare the elastic restitution of energy and the energy dissipated during the creation of a surface fissured, provided by key word GC.*

*The joined elements use operand GC and operands SIGM\_C and SAUT\_C within the framework of the law of behavior BARENBLATT.*

### **Key word factor SECH\_NAPPE**

*The coefficient of diffusion, characterizing the nonlinear equation of drying, is expressed using one tablecloth, tabulée function of the water concentration, variable of calculation, and the temperature, variable*

*auxiliary of calculation, given in the form of a structure of data of the evol\_ther type. For resolution of drying by operator THER\_NON\_LINE, the concentration out of water is comparable with one*

*temperature, of type "TEMP".*

*For the coherence of the data, parameters of the tablecloth, i.e. the variable of calculation and auxiliary variable cannot be of the same type. A new type of variable was added in DEFI\_NAPPE, the "type of the temperature calculated drying before", "TSEC", which corresponds indeed to a temperature.*

)

***BETON\_DOUBLE\_DP makes it possible to define all the characteristics associated with the law with behavior with double criterion of Drücker Prager. In complement of these characteristics, the modulus of elasticity, the Poisson's ratio, and the thermal dilation coefficient, as well as the coefficients of withdrawal endogenous and of withdrawal of desiccation, must be defined under key word ELAS for the coefficients realities, or ELAS\_FO, for the coefficients defined by functions, or tablecloths. All them characteristics of the model, (E, naked, f' C, f' T, Gc, WP) on type [fonction\*] can depend on one or of two variables among the temperature, the hydration and drying. When they depend on temperature, they are functions of the maximum of the temperature reached during the history of loading, which is stored for each point of Gauss, in the form of variable intern. This makes it possible to take into account the irreversible variations of these characteristics to high temperature.***

### 7.8.4 Operands

***LONG\_CARA***

***This operand makes it possible to overload the automatically calculated characteristic length, for each mesh, according to its dimensions (starting from its surface in 2D, its volume in 3D).***

***The automatically calculated characteristic length allows, when the smoothness of the grid evolves/moves from one calculation to another, to preserve stable results by avoiding the phenomena of localization. This length calculated automatically or given by the user, conduit with the value of ultimate work hardening in traction according to the formula (for a linear work hardening post-peak):***

**2 G**

.

**U ()**

**T ()**

=

**lc. ft ()**

*In the particular case of a grid containing of the adjacent meshes whose dimensions are very different, ultimate work hardenings of model **BETON\_DOUBLE\_DP** calculated starting from the length*

*characteristic of the meshes are consequently very different, which can generate problems of convergence or to lead to a not very physical state of stresses. (This characteristic length is calculated starting from the volume of the current mesh). For this reason, one proposes to give possibility with the user of defining an average length which overloads the characteristic length calculated for each mesh. The defect of Code\_Aster is the characteristic length calculated for each mesh.*

*To choose an arbitrary and identical length for all the meshes can also generate difficulties of convergence. The best solution consists in creating a network of which variations of dimensions meshes respect the direction of variation of the stress field, and to use the length characteristic calculated automatically according to the size of the meshes. The overload by **LONG\_CARA** must be to hold for particular cases, when the user cannot freely intervene on the grid.*

*If the user defines the characteristic length in material, it will choose a couple (**WP,***

**2 G**

**. T ()**

**LONG\_CARA)** such as

*the value is worth which it wishes for ultimate work hardening in traction **U.***

**lc. ft ()**

*(The usual value of the deformation associated with ultimate work hardening in traction with an average concrete is of **5.E-4**).*

**NADAI\_B**

***The law of behavior NADAI\_B is a model of behavior of the integral concrete of plastic deformations in compression and a model of cracking in traction. This model allows to represent the behavior of the concrete under cyclic loading, a detailed attention being brought to the management of the openings and closings of the cracks.***

***For behaviour in compression, modeling is developed within the framework of standard elastoplasticity: threshold of reversibility (standard Drücker-Prager), normal plastic flow associated.***

***For behaviour in traction, the model is within the framework of cracking distributed. A threshold of reversibility in traction is defined. The first cracking is detected in a geometrical point given when the constraints exceed the threshold in traction for the first time. The point is then declared fissured, direction of the crack being direction perpendicular to the principal constraint major at this moment. The law of behavior of the concrete in this point becomes an orthotropic law then, them axes of orthotropism being those parallel and perpendicular to the crack (of which the orientation of will change more)***

***The parameters of the law are given starting from a test in uniaxial pressing, resistance in traction of the concrete:  $F$***

***and of the deformation with rupture in traction: rupture***

***Stress-strain curve in compression, one deduces the stress-strain curve plastic in compression.***

***BETON\_UMLV\_FP***

*The law of creep UMLV supposes a total decoupling between the spherical components and deviatoric: the deformations induced by the spherical constraints are purely spherical and the deformations induced by the deviatoric constraints are purely deviatoric. In addition, clean deformation of creep is supposed to be proportional to internal relative moisture:*

*Spherical part: S*

*= H F (S*

*) and, left deviatoric: D = H (~*

*F*

*)*

*Where H indicates internal relative moisture.*

*The model of behavior BETON\_UMLV\_FP is a nongrowing old viscoelastic model developed in partnership with the University of Marne-the-Valley to describe the clean creep of concretes. It is particularly adapted to the multiaxial configurations by not presupposing the value Poisson's ratio of creep.*

*The spherical constraints are at the origin of the migration of the water absorptive with the interfaces between*

*hydrates on the level of the macroporosity and absorptive within microporosity in porosity capillary. Diffusion of the inter-lamellate water of the pores of hydrates towards capillary porosity be carried out in an irreversible way. The total spherical deformation of creep is thus written like*

*summon of a reversible part and an irreversible part:*

*fs*

*fs*

*fs*

=

+

{

*R*

{

*I*

*part*

*part*

Date:

22/02/06

Author (S):

Key **J.P. LEFEBVRE**

:

*U4.43.01-II Page*

: 100/148

*One will be able to refer to [§ 3.3.2.3] of the documentation of order STAT\_NON\_LINE [U4.51.03].*

*One then defines the “total” pressures and the temperature by:*

*p*

*pddl*

*pref*

;

*T*

*Tddl Tref*

=

+

=

+

*Values written by*

*ddl*

*ddl*

*IMPR\_RESU are the nodal unknown factors p*

*and T*

*. In the same way them*

*boundary conditions must be expressed compared to the nodal unknown factors.*

*On the other hand, in fact the pressures and the total air temperature are used in the laws of*

*p  
R  
D  
dp  
behavior*

*=  
T  
L  
L  
=  
-*

*for perfect gases,  
3 dT for the liquid and in  
M*

*K  
L  
L  
L  
relation capillary saturation/pressure.*

*Let us note that the nodal values can be initialized by key word ETAT\_INIT of the order  
STAT\_NON\_LINE.*

*The user must be very careful in the definition of the values of THM\_INIT: indeed, the definition of  
several materials with values different from the quantities defined under THM\_INIT leads to  
discontinuous values initial of the pressure and the temperature, which is not in fact not compatible  
with the general treatment which is made of these quantities. We thus advise with the user  
following step:*

*.  
if at the beginning, there is a uniform field of pressure or of temperature, one returns it directly  
by key word THM\_INIT,*

*.  
if there is a nonuniform field, one enters for example a reference by key word THM\_INIT  
order initial DEFI\_MATERIAU, and values compared to this reference by  
key word ETAT\_INIT of order STAT\_NON\_LINE.*

### **9.2.2 Operand TEMP**

*Temperature of reference ref.*

*T*

### **9.7.2 Operand R\_GAZ**

*Constant of perfect gases.*

### **9.7.3 Operand RHO**

*For the hydraulic behaviors homogenized density.*

**Note:**

*For modelings utilizing it thermal, one uses also the density of solid matter constituents, which one reads under key word RHO of the key word factor ELAS.*

### **9.7.4 Operand CP**

*For the thermal behaviors specific heat with constant constraint of the solid alone.*

### **9.7.5 Operand BIOT\_COEF**

*Coefficient of Biot.*

### **9.7.6 Operand SATU\_PRES**

*For the unsaturated material behaviors (LIQU\_VAPE\_GAZ, LIQU\_AD\_GAZ\_VAPE, LIQU\_GAZ, LIQU\_GAZ\_ATM), isotherm of saturation function of the capillary pressure.*

### **9.7.7 Operand**

## ***D\_SATU\_PRES***

***For the unsaturated material behaviors (LIQU\_VAPE\_GAZ, LIQU\_AD\_GAZ\_VAPE, LIQU\_GAZ, LIQU\_GAZ\_ATM), derived from saturation compared to the pressure.***

### ***9.7.8 Operand***

#### ***PESA\_X***

***Gravity according to X, used only if the modeling chosen in AFFE\_MODELE includes 1 or 2 variable of pressure.***

### ***9.7.9 Operand PESA\_Y***

***Gravity according to y, used only if the modeling chosen in AFFE\_MODELE includes 1 or 2 variable of pressure.***

### ***9.7.10 Operand PESA\_Z***

***Gravity according to Z, used only if the modeling chosen in AFFE\_MODELE includes 1 or 2 variable D pressure.***

***Instruction manual***

### ***9.7.11 Operand PERM\_IN***

***Intrinsic permeability: function of porosity (in the isotropic case).***

***The permeability to the traditional direction K, whose dimension is that a speed is calculated way***

*following:*

*K K*

*K*

*int*

*rel*

*=*

*G where K*

*L*

$\mu$

*int is the intrinsic permeability, Krel the relative permeability,  $\mu$  viscosity, L density of the liquid and G the acceleration of gravity. Kint is in fact one diagonal tensor, in the isotropic case its three components are equal to the well informed value.*

#### *9.7.12 Operand PERMIN\_X*

*In the orthotropic case, component in X of the intrinsic tensor of permeability. In this case, PERMIN\_Y and PERMIN\_Z are obligatory.*

#### *9.7.13 Operand PERMIN\_Y*

*In the orthotropic case, component in there of the intrinsic tensor of permeability.*

#### *9.7.14 Operand PERMIN\_Z*

*In the orthotropic case, component in Z of the intrinsic tensor of permeability.*

#### *9.7.15 Operand PERM\_LIQU*

*Permeability relating to the liquid: function of saturation.*

#### *9.7.16 Operand D\_PERM\_LIQU\_SATU*

*Derived from the Permeability relating to the liquid compared to saturation: function of saturation.*

#### *9.7.17 Operand PERM\_GAZ*

*Permeability relating to gas: function of the saturation and the gas pressure.*

#### *9.7.18 Operand D\_PERM\_SATU\_GAZ*

*Derived from the permeability to gas compared to saturation: function of the saturation and of gas pressure.*

#### *9.7.19 Operand D\_PERM\_PRES\_GAZ*

*Derived from the permeability to gas compared to the gas pressure: function of the saturation and of*

*gas pressure.*

### **9.7.20 Operand FICKV\_T**

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of temperature for the diffusion of the vapor in the gas mixture. The coefficient of Fick which can be function of saturation, the temperature, the pressure of gas and the steam pressure, one defines it like a product of 4 functions: FICKV\_T, FICKV\_S, FICKV\_PG, FICKV\_VP. In the case of LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, only FICKV\_T are obligatory.*

### **9.7.21 Operand FICKV\_S**

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of saturation for the diffusion of the vapor in the gas mixture.*

*Instruction manual*

*U4.4- booklet: Modeling*

*HT-62/06/004/A*

### **9.7.22 Operand *FICKV\_PG***

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of gas pressure for the diffusion of the vapor in the gas mixture.*

### **9.7.23 Operand *FICKV\_PV***

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of steam pressure for the diffusion of the vapor in the gas mixture.*

### **9.7.24 Operand *D\_FV\_T***

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, derived from coefficient *FICKV\_T* compared to the temperature.*

### **9.7.25 Operand *D\_FV\_PG***

*For behaviors LIQU\_VAPE\_GAZ and LIQU\_AD\_GAZ\_VAPE, derived from coefficient *FICKV\_PG* compared to the gas pressure.*

### **9.7.26 Operand *FICKA\_T***

*For the behavior LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of the temperature for diffusion of the air dissolved in the liquid mixture. The coefficient of Fick which can be a function of saturation, the temperature, the pressure of dissolved air and the pressure of liquid, one defines it as one product of 4 functions*

*: *FICKA\_T*, *FICKA\_S*, *FICKV\_PA*, *FICKV\_PL*. In the case of *LIQU\_AD\_GAZ\_VAPE*, only *FICKA\_T* are obligatory.*

### **9.7.27 Operand FICKA\_S**

*For the behavior LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of saturation for diffusion of the air dissolved in the liquid mixture.*

### **9.7.28 Operand FICKA\_PA**

*For the behavior LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of the pressure of dissolved air for the diffusion of the air dissolved in the liquid mixture.*

### **9.7.29 Operand FICKA\_PL**

*For the behavior LIQU\_AD\_GAZ\_VAPE, coefficient of Fick function of the pressure of liquid for the diffusion of the air dissolved in the liquid mixture.*

### **9.7.30 Operand D\_FA\_T**

*For behavior LIQU\_AD\_GAZ\_VAPE, derived from coefficient FICKA\_T compared to temperature.*

### **9.7.31 Operand LAMB\_T**

*For multiplicative behavior THER\_POLY left the thermal conductivity of the mixture depending on the temperature (cf [R7.01.11]).*

*For thermal behavior THER\_HOMO conductivity of the mixture.*

*This operand is obligatory in the thermal case.*

### **9.12 Key word factor CJS**

*The law (Cambou, Jaffani, Sidoroff) is a law of behavior for the grounds. It comprises three mechanisms, one corresponds to nonlinear elasticity, another corresponds to a plasticization for isotropic states of stresses, and the third mechanism corresponds to a dependent plasticization in a state of stress déviatoire. The document [R7.01.13] described with precision the equations corresponding.*

*The elastic characteristics must be defined under key word ELAS.*

*Law CJS covers three possible forms (CJS1, CJS2 and CJS3), according to whether one authorizes or not the activation of the nonlinear mechanisms.*

*Table Ci below gives the mechanisms activated for three levels CJS1, CJS2 and CJS3:*

***Elastic mechanism isotropic plastic Mechanism***

***Plastic mechanism***

***déviatoire***

***CJS1***

*linear*

*not activated*

*activated, perfect plasticity*

***CJS2***

*nonlinear*

*activated*

*activated, isotropic work hardening*

***CJS3***

*nonlinear*

*activated*

*activated, kinematic work hardening*

**Note:**

*By adopting the correspondence of the parameters for the limiting states, it is possible to use behavior CJS1 to model a law of Mohr Coulomb in soil mechanics.*

*Indicate the plastic constraint. This operand is related to the combination of the binding fraction  $6C \cos ()$*

*C with the angle of friction in the following way:  $SY =$*

*.*

*$3 - \sin ()$*

### **9.14.6 Operand H**

*Indicate the module of work hardening,  $H < 0$  if the law is lenitive. This operand is obligatory for work hardening of a linear type (operand `WORK HARDENING = `LINEAR ``).*

### **9.14.7 Operand SY\_ULTM**

*Indicate the ultimate constraint. This operand is obligatory for work hardening of a parabolic type (operand `WORK HARDENING = `PARABOLIC ``).*

## **9.15 Key word BARCELONA factor**

*The model of Barcelona describes the elastoplastic behavior of the unsaturated grounds coupled with hydraulic behavior (cf [R7.01.14] for more detail). This model is reduced to the model Cam\_Clay in the saturated case. Two criteria intervene: a mechanical criterion of plasticity (that of Cam\_Clay) and a hydrous criterion controlled by suction (or capillary pressure). It cannot be used that within the framework of behaviors THHM and HHM. Characteristics necessary to model must be given under this key word and key words `CAM_CLAY` and `ELAS`. It is thus obligatory to inform the parameters of key words `CAM_CLAY` and `ELAS`.*

### **10.3 Key word factor ECRO\_ASYM\_LINE (cf [R5.03.09])**

***It makes it possible to model a behavior with linear isotropic work hardening, but with limits of elasticity and different modules of work hardening in traction and compression. This is used by the model of behavior 1D VMIS\_ASYM\_LINE, usable for elements of bar.***

***Elastic behaviour in traction and compression is the same one: even Young modulus.***

***There are two fields of isotropic work hardening defined by RT and RC. The two fields are independent one of the other. We adopt an index T for traction and C for compression.***

**YT**

***Effort limits in traction. In absolute value.***

**YC**

***Effort limits in compression. In absolute value.***

**Pt**

***Plastic deformation cumulated in traction. Algebraic value.***

**PC**

***Plastic deformation cumulated in compression. Value***

*algebraic.*

*ETT*

*Slope of work hardening in traction.*

*Etc*

*Slope D`work hardening in compression.*

*The equations of the model of behavior are:*

.

678

$\sigma = \sigma - -$

1

-  $\sigma_{th}$

$\sigma = \sigma$

$\sigma$

+

$C$

$\sigma T$

$\sigma = \sigma$

$C$

$\sigma C$

$\sigma = \sigma$

$T$

$\sigma T$

-  $R p 0$

$T ($

$T)$

- -  $R p 0$

$C ($

$C)$

*with*

$\dot{\epsilon}_p$   
 $= 0$  if  $\dot{\epsilon} - R_p < 0$   
 $C$   
 $C$  (  
 $C$ )

$\dot{\epsilon}_p$   
 $0$  if  $\dot{\epsilon} = R_p$   
 $C$   
 $C$  (  
 $C$ )

$\dot{\epsilon}_p = 0$  if  $\dot{\epsilon} - R_p < 0$   
 $T$   
 $T$  (  
 $T$ )

$\dot{\epsilon}_p 0$  if  $\dot{\epsilon} = R_p$   
 $T$   
 $T$  (  
 $T$ )

where:

$\dot{\epsilon}_p$  & PC: speed of plastic deformation in compression,

$\dot{\epsilon}_p$  & Pt: speed of plastic deformation in traction

HT: thermal deformation of origin:  $HT = (T - ref.$

$T)$ . is defined under ELAS.

It is noticed that one cannot have simultaneously plasticization in traction and compression: that is to say

$\dot{\epsilon}_p C = 0$ , either  $\dot{\epsilon}_p T = 0$ , or both is null.

### 10.3.1 Syntax

$ECRO\_ASYM\_LINE = \_F (DT\_SIGM\_EPSI$   
 $= RT,$

***SY\_T = yT,***

***private individuals***

***11.1 Key word factor LEMAITRE\_IRRA***

***Characteristics (specific to the irradiation) of the creep of the pencils or fuel assemblies (behavior LEMAITRE\_IRRA of STAT\_NON\_LINE).***

***The elastic characteristics must be defined under key word ELAS or ELAS\_FO.***

***The uniaxial form of the law of growth is:***

$$S(T) = (At + b) T$$

***G***  
***. D***

***0***

***T***

***where is the neutron flux and D the fluence, recovered in STAT\_NON\_LINE by the key word***

***0***  
***IRRA of VARI\_COMM. T is in °C.***

***If one adopts a modeling 1D (the behavior is then applied to an element of beam in the axial direction, cf [R5.03.09]), this uniaxial form is used just as it is.***

***On the other hand, for modelings 2D and 3D, the law of growth is written (cf [R5.03.08]):***

***S***

$$G(T) = (At + b) T$$

***.***

***0***

***D***

***0***

***G***

***1 0 0***

***with:***

***0***

**= 0 0 0**

**G**

**0 0 0**

**1R**

*One must then define using operand ANGLE\_REP of the MASSIVE key word of the operator AFFE\_CARA\_ELEM local axes corresponding to the R1 reference mark (see [U4.42.01]). This operand awaits 3 nautical angles of which one uses only the 2 first (the third can thus be unspecified).*

*The parameters of growths are provided behind key words GRAN\_A, GRAN\_B and GRAN\_S. One informs four key words QSR\_K, BETA, PHI\_ZERO, L (the other parameters of creep are identical to those of behavior LEMAITRE) and behaviour in creep is then according to:*

**N**

**Q**

**1**

**-**

**eq**

**R (T +T0)**

**&p =**

**+ L E**

**(T =**

**•**

**0**

**)**

**1 /**

**p m K**

**273,15 C**

**0**

*where is the neutron flow calculated starting from the fluence recovered in STAT\_NON\_LINE by operand IRRA of key word VARI\_COMM (see [R5.03.08] or [R5.03.09] according to modeling). T is in °C.*

*If it is wished that the behavior not depend on the fluence, but comprises nevertheless the term in exp (- Q/RT), it is possible, only for modelings 2D and 3D, to use key word LEMAITRE\_IRRA in STAT\_NON\_LINE by informing key word LEMAITRE\_IRRA in DEFI\_MATERIAU. It is then necessary imperatively to affect UN\_SUR\_K, A, B, S with zero and PHI\_ZERO with one. Under these conditions, it is not necessary to define a field of fluence.*

***ECRO\_RES = gamma\_ressort***

***Parameter of work hardening allowing to treat the friction of the springs (in N/m)  
This parameter does not have a physical direction, and is introduced only to help the convergence of calculation  
when there is slip (idem perfect plasticity).***

***FORC\_SER = forc\_serrage***

***Force tightening (positive) initial pencil in the grid (equal to the force applied to the springs)  
(in NR).***

***DIST\_BOS = distance\_bossette***

***Outdistance between the bosses (in m).  
This parameter must be readjusted if one uses only one discrete to model several connections  
grid-pencil, and thus does not correspond necessarily to the true distance between the bosses  
measured on the grids of the assembly.***

#### ***11.4 Key word factor GATT\_MONERIE***

***Thermomechanical law of behavior of fuel “GATT-Monerie” in order to simulate tests  
of indentation. This law of behavior is an isotropic élasto-viscoplastic law without work hardening  
whose specificities are:***

- the potential of dissipation is the sum of two potentials of the Norton type (without threshold),***
- the fuel having a residual porosity likely to evolve/move in compression  
(thickening), this potential depends, in addition to the equivalent constraint, of the constraint  
hydrostatic.***

***The two internal variables of this model are the plastiquecumulée deformation and the fraction  
voluminal of porosity.***

**Behavior “DIS\_CONTACT”:**

**Behavior concerning the degrees of freedom of translation**

*COULOMB = driven*

*Value of the coefficient of friction.*

*EFFO\_N\_INIT = Finished*

*Initial normal effort in the spring (in general negative, so that there is contact at the initial moment).*

*KT\_ULTM = ktu*

*Slope of regularization which simulates a nonperfect slip.*

*RIGI\_N\_FO = Fn (T)*

*Multiplying function (depend on time) of rigidity, in general decreasing with time, to simulate the effect of the irradiation on the rigidity of the spring.*

*RIGI\_N\_IRRA = FF (fluence)*

*Multiplying function (depend on the fluence) of rigidity, in general decreasing with fluence, to simulate the effect of the irradiation on the rigidity of the spring. To define this function, it is necessary*

*to use order DEFI\_FONCTION and to take for example as NOM\_PARA, “INST”: for the moment the fluence does not form part of the possible NOM\_PARA.*

**Behavior concerning the degrees of freedom of rotation**

*RELA\_MZ = f\_mz*

*Curve (moment) according to DR. (degree of rotation)*

$ANGLE\_1 = a1, MOMENT\_1 = m1,$   
 $ANGLE\_2 = a2, MOMENT\_2 = m2,$   
 $ANGLE\_3 = a3, MOMENT\_3 = m3,$   
 $ANGLE\_4 = a4, MOMENT\_4 = m4,$

*Definition of the curve moment-angle of the characteristic in rotation of the connection grid-pencil, 2 parameters moment and angle depend on the temperature and the fluence.*

$C\_PRAGER\_MZ = cpr$

*Constant of Prager which makes it possible to define mixed work hardening.*

***Behavior “DIS\_CHOC”:***

$COULOMB = driven$

*Value of the coefficient of friction*

$RIGI\_NOR = kN$

*Value of the normal rigidity of shock. If RIGI\_NOR is present it is this value which is taken in count. If it is not present, the discrete elements to which one affects this material must have their stiffness defined in addition (for example using order AFFE\_CARA\_ELEM with key words DISCRETE or RIGI\_PARASOL).*

$RIGI\_TAN = Kt$

*Value of the tangential rigidity of shock*

$AMOR\_NOR = Cn$

*Value of the normal damping of shock*

$AMOR\_TAN = Ct$

*Value of the tangential damping of shock*

### 3 *Catalogue Matériaux Aster*

*Code\_Aster has a Catalogue Materials whose objectives are:*

- to provide the users, the data materials necessary to the realization of studies numerical,*
- to ensure the perennality of information,*
- to guarantee the reliability and the coherence of the data available,*
- and to facilitate and automate the access to the data.*

*In Code\_Aster, the material is defined by a whole of characteristics necessary to the setting in work of a law of behavior, which is introduced by the general order **DEFI\_MATERIAU**.*

*In the Catalogue Materials, the material is indexed by its designation in standard AFNOR.*

*The Catalogue Materials distinguishes two types of materials according to the type of study:*

*• the “material of reference” for generic studies. It corresponds to a whole of products manufactured according to the same well defined specification. It is characterized by values median, minimal and maximum typical of the population concerned. It is it material which it is advised to use if one does not have a perfect description of material to be modelled,*

*• the “particular material” for specific studies. It corresponds to a product well identified or with a concept of material given. This material is characterized by values specific of its properties, together with extreme values related to the heterogeneity of material and/or with uncertainty on the values. This material is finely documented so to avoid its systematic use without precaution.*

*In addition, one can index various materials (of reference or private individual) corresponding to even designation AFNOR. The RCC-M distinguishes, for the same designation AFNOR, them characteristics material following the technical specification of reference, the type of product (forged, rolled-iron product, tube, sheet,...) and dimensions of the component. In order to take account of this dimension additional, in the Catalogue Materials, one associates each material a letter of the alphabet.*

*To summarize, in the Catalogue Materials the materials are indexed by a chain of*

*characters which is composed of the concatenation:*

- *designation in standard AFNOR,*
- *word ref. (if material of reference) or BY (if particular material),*
- *of a letter of the alphabet.*

*For example: 18MND5\_REF\_A*

*The Catalogue Materials is presented in two distinct forms:*

- *a form “files” usable by Code\_Aster by order INCLUDE\_MATERIAU.  
It is a whole of files having for name the character string previously  
described (for example 18MND5\_REF\_A) and for extension one of the character strings  
following: NOMI (for the median values), MINIS (for the minimal values) and MAXIMUM  
(for the maximum values),*

- *a form “cards”, where the user can consult the characteristics materials in form  
tables and to obtain the origin of the characteristics. This shape of the catalogue is accessible  
on the site of Code\_Aster: [www.code-aster.org](http://www.code-aster.org) under the mitre “Use”. Each card  
material is the subject of an independent validation by department MMC.*

#### **4 Operands**

**NOM\_AFNOR/TYPE\_MODELE/ALTERNATIVE/  
TYPE\_VALE**

*These operands make it possible to choose material to be used and thus to define its name according to the rule presented in [§3].*

**NOM\_AFNOR**

=

**nomafnor**

**[K8]**

*Allows to specify the designation of material in standard AFNOR (for example: 18MND5).*

**TYPE\_MODELE =/**

**“Ref.”,**

**/**

**“BY”,**

*Allows to specify if they are the characteristics of material of reference or those of particular material which one wishes to use.*

**ALTERNATIVE**

=

**/**

**“A”,**

**.....**

**/**

**“Z”,**

*Allows to specify the alternative of the material which one wishes to use (the characteristics are in general different according to the thickness or the diameter and this for the same designation in standard AFNOR). The paragraph of description of material of the card material allows to know the alternative interesting the user.*

**TYPE\_VALE**

=

**/**

**“NOMI”,**

**/“MAXIMUM”,**

*/“MINI”,*

*Allows to specify if one wants to use the median values, minimal or maximum.*

**5 Operand**  
**NOM\_MATER**

**NOM\_MATER**

**=**

*to subdue*  
**[K8]**

*Allows the user to specify the name which will be affected with the MATER concept used in Aster. The user can thus carry out several INCLUDE\_MATERIAU in the same Aster calculation, with condition of giving different names of MATER concept to each call to INCLUDE\_MATERIAU.*

**Instruction manual**  
**U4.4- booklet: Modeling**

**:**  
**U4.43.02-C Page**  
**: 5/6**

**6 Word**  
**key**  
**EXTRACTION**

*The values of characteristics material contained in the Catalogue Materials are generally*

*tables of values depending on the temperature. So one did not inform in the Catalogue Materials that certain key words control ratios **DEFI\_MATERIAU**: those for which operands are defined by functions (for example: **ELAS\_FO**, **THER\_NL**,...). On the other hand, words key factors for which the operands are defined by realities (for example: **ELAS**,...) are not not well informed in the various files composing the form "files" of the Catalogue Materials. One can however generate these key words in order **DEFI\_MATERIAU** by the key word **EXTRACTION** by specifying the behavior which one wishes to generate and by specifying the value of temperature to which one wishes to extract the values from the function.*

## **6.1 Operand**

### **COMPOR**

#### **COMPOR**

=

*compor*

**[K16]**

*Behavior to be created in order **DEFI\_MATERIAU** (for example **ELAS** from **ELAS\_FO** for a given temperature) (must correspond to a key word factor of **DEFI\_MATERIAU**).*

## **6.2 Operand**

### **TEMP\_EVAL**

#### **TEMP\_EVAL**

=

*temp*

**[R8]**

*Temperature to which, one wishes to extract the values from the characteristics materials. By example, one creates in order **DEFI\_MATERIAU** the operand  $E = E$  under the key word  $0$  factor **ELAS** by extracting the value with  $T$  from the operand  $E = E(T)$  definite under the key word  $0$  factor **ELAS\_FO**. To be able to carry out such an operation, it is necessary of course, that the word key **ELAS\_FO** is defined in the file associated with selected material. The interpolation, if need is, is linear, except if it is not authorized.*

## **7 Operand**

### **UNITE\_LONGUEUR**

**UNITE\_LONGUEUR =/“Me**

,  
**[DEFECT]**

/

**“MM”**

,

*Allows to use the data of the catalogue material with the millimetre like unit of length.*

*The values indicated in the catalogue material are and remain in meters. If the user specifies UNITE\_LONGUEUR = “MM” in the order INCLUDE\_MATERIAU, that means that the user wishes to handle units of length in millimetres, and orders it INCLUDE\_MATERIAU carries out the transformation of the units.*

**8 Operand**

**INFORMATION**

**INFORMATION**

=

/

1,

**[DEFECT]**

/

2,

1

*no impression of the contents of the file included,*

2

*impression of the contents of the file included, in the file “MESSAGE”.*

### **3 General information**

*This order is used to affect the material characteristics on the finite elements of the model (even if in fact the meshes of the grid are really affected). These characteristics material are defined by the materials which one affects on the meshes (key word **MATER**). Each material contains a certain number of parameters (Young modulus, density,...). These parameters can be related to certain variables. We will call these variables of “variable of order”.*

*Currently, the variables of order used (in mechanics) are the temperature, the hydration, drying, phases metallurgical, irradiation, corrosion,... But only affected variables via order **AFFE\_MATERIAU** for the moment the irradiation (**IRRA**) and corrosion (**CORR**) are.*

### **4 Operands**

#### **4.1**

#### **GRID**

**GRID** = my,

*Name of the grid (or the skeleton) which one wants to affect by material characteristics.*

**Note:**

*The operation of assignment is the same one for the meshes of a skeleton as for the meshes of one grid. In the continuation of the document, one will always say grid to simplify.*

*When one affects materials on the meshes of a skeleton, it is that one wants to calculate*

*constraints (for example) on the meshes of postprocessing (coarser).*

## ***4.2 Place of assignment***

### ***AFFE***

*Key word factor which makes it possible to affect various materials on “pieces” of the grid.*

*/ALL = “YES”,*

*This key word makes it possible to affect on all the meshes of the grid.*

*/GROUP\_MA = l<sub>gma</sub>,*

*This key word makes it possible to affect on a list of groups of meshes of the grid.*

*/  
NET  
=  
l<sub>ma</sub>,*

*This key word makes it possible to affect on a list of meshes of the grid.*

*With each group of meshes, (key word GROUP\_MA) or each list of meshes (key word NETS), or with all the grid (key word ALL) is affected a material chechmate, which is a concept product by one of operators DEFINI\_MATERIAU [U4.43.01] or DEFINI\_COQU\_MULT [U4.42.03].*

*Let us recall that order DEFINI\_MATERIAU [U4.43.01] makes it possible to define the parameters of relations of behavior to be used for a mechanical, thermal, acoustic analysis. order DEFINI\_COQU\_MULT [U4.42.03] allows to define a homogenized material representative of a laminated material multi-layer.*

*If a mesh appears explicitly (or implicitly) in several occurrences of the key word factor AFFE, the rule of overload is applied: it is the last assignment which precedes [U2.01.08].*

***J. Key PELLET***

***:***

***U4.43.03-II Page***

***: 4/6***

## 4.3

***Quantities to be affected***

### ***4.3.1 Notice concerning calculations of breaking process***

***In general, the material characteristics must be known finite elements modelling “matter”: “voluminal” elements (or of structure). The finite elements of “skin” are there for to apply boundary conditions and do not have to know the material properties of the matter subjacent. An exception exists for the calculation of option CALC\_K\_G of the operators . For these calculations, the finite elements modelling the lips of the crack must be affected by same material as the “voluminal” elements subjacent.***

### ***4.3.2 Operand***

***MATER***

***MATER = chechmate,***

***Name of the material which one wants to affect.***

***In the case general, each mesh is affected only by one material. Sometimes, it is necessary to indicate a material list when the nonlinear mechanical behavior is obtained by order DEFI\_COMPOR [U4.43.06].***

### ***4.3.3 Operand***

***TEMP\_REF***

***TEMP\_REF = Tref,***

***The temperature of Tref reference introduced behind key word TEMP\_REF is the temperature for which it does not have there thermal deformation (cf [R4.08.01]).***

*If the thermal dilation coefficient (of which the value is introduced into the order HT*

*DEFI\_MATERIAU [U4.43.01]) does not depend on the temperature:*

*(T) = (T - ref.  
T).*

*If the thermal dilation coefficient depends on the temperature the mathematical expression allowing the calculation of the thermal deformation differs according to the specification from thermal dilation coefficient in order DEFI\_MATERIAU:*

*.  
the values of the thermal dilation coefficient (introduced into DEFI\_MATERIAU) have summer determined by tests of dilatometry carried out at the Tref temperature. In this case, key word TEMP\_DEF\_ALPHA should not be specified in the order DEFI\_MATERIAU and the thermal deformation are calculated by the expression:*

*HT (T) = (T) (  
HT  
T - ref.  
T) and (ref.  
T) = 0*

*where (T) is well informed under the key word ALPHA (or ALPHA\_\*) in DEFI\_MATERIAU.*

*.  
the values of the thermal dilation coefficient are determined by tests of dilatometry which took place at a Tdef temperature different from the temperature from Tref reference. It is then necessary to carry out a change of reference mark in the calculation of the deformation thermics [R4.08.01].*

*HT (T) = HT (T) - HT  
m  
m (ref.  
T)*

*where thm is the thermal deformation measured (definite compared to the temperature Tdef),*

*HT is the thermal deformation calculated (definite compared to the temperature Tref).*

#### **4.3.4 Operand**

**SECH\_REF**

**SECH\_REF: c0 [R]**

*c0 represents the water content initial of the concrete. The user must provide this number when it does one mechanical calculation (MECA\_STATIQUE or STAT\_NON\_LINE) with a loading of the type SECH\_CALCULEE.*

*c0 must be given in the same units as the “drying” of SECH\_CALCULEE (for example in L/m3). This unit must be coherent with parameter DEFI\_MATERIAU/ELAS\_FO/K\_DESSIC.*

*With this water content initial, the withdrawal of desiccation is null since:  
 $EPS_{rd} = K_{DESSIC} (C0 - C)$ .*

#### **4.4 Word**

**key**

**AFFE\_VARC**

*This key word factor makes it possible to affect fields of variables of order on the meshes of grid. An event of the key word is used to affect a variable of order. For the moment, both variables of order usable in this order (IRRA and CORR) have each one only one*

*component (IRRA and COOR) but it is envisaged for example that a deformation (6 components EPXX, EPYY,...) can be a variable of order.*

#### **4.4.1 Operand**

**NOM\_VARC**

**NOM\_VARC = nomvarc,**

*Name of the variable of order which one wants to affect (IRRA or CORR).*

#### **4.4.2 Operands**

**TOUT=' OUI', GROUP\_MA=lgma, MAILLE=lmail**

*These key words make it possible to indicate the zone to be affected.*

#### **4.4.3 Operand**

**CHAMP\_GD=chvarc**

*This key word makes it possible to associate the variable of order nomvarc the field chvarc. This field is a field of realities (not of functions). It is thus independent of time and will be used throughout transitory calculations.*

*If the values of the variable of order are dependent on time, it is necessary to use key word EVOL (see below).*

*In the field chvarc, the program will seek a of the same component name than nomvarc.*

#### **4.4.4 Operands**

**EVOL=evovarc and NOM\_CHAM=nomsym**

*These key words make it possible to associate the variable of order nomvarc the transient evovarc. key word NOM\_CHAM makes it possible to indicate the reference symbol of the fields of SD\_résultat to be used.*

*By defect, the code chooses NOM\_CHAM=' IRRA' for NOM\_VARC=' IRRA' and NOM\_CHAM=' CORR' for*

*NOM\_VARC=' CORR'. The fields are fields of realities (not functions). In these fields, it program will seek a of the same component name than nomvarc.*

#### **4.4.5 Operand**

**VALE\_REF=vref**

*This key word makes it possible to define a value of “reference” for the variable of order nomvarc. By example, when drying is treated like a variable of order in the key word AFFE\_VARC, key word VALE\_REF will replace key word current SECH\_REF. 2 current variables (IRRA and CORR) do not have a value of reference.*

**Author (S):**

**J. Key PELLET**

**:**

**U4.43.03-II Page**

**: 6/6**

**5 Examples**

**Example 1**

**chmat = AFFE\_MATERIAU (GRID = my, AFFE = (**

**\_F (ALL = "YES", MATER = steel),**

**\_F (MAILLE= ("ma1", "ma2", "ma3"), MATER=alu,  
TEMP\_REF=20.),),**

**)**

**On the whole of the grid (except the meshes: ma1, ma2, ma3) are affected the material of name steel with the temperature of reference per defect: 0.**

**On the meshes ma1, ma2, ma3 are affected the material aluminum with the temperature of reference 20.**

**Example 2**

*Assignment on all the grid of the material CHECHMATE whose certain parameters are related to irradiation. The temporal evolution of the irradiation is given via the SD result EVOL = FLUENC.*

```
CHMAT = AFFE_MATERIAU (GRID = MA,
AFFE = _F (TOUT=' OUI', MATER = CHECHMATE,),
AFFE_VARC=_F (NOM_VARC=' IRRA', EVOL =FLUENC,),
)
```

**Example 3**

*Use of the variable of order “NEUT1” to simulate a dependence of the coefficients materials according to the Young modulus.*

*In this example (resulting from the case test ssnv130c), one wants to illustrate the possibility of using a field of*

*Young modulus whom one supposes known (CHYOUNG). For example, this field is read in a file (LIRE\_CHAMP) or it is the result of a calculation. One then will define a material for which Young modulus (key word E) is the function “identity” of variable “NEUT1” and the field is affected CHYOUNG like variable of order “NEUT1”.*

```
CHYOUNG=...
```

```
NU_F=DEFI_CONSTANTE (VALE=0.3)
```

```
E_F = DEFI_FONCTION (NOM_PARA=' NEUT1', VALE= (- 1.E-9, - 1.E-9, 1.E+9,1.E+9));
```

```
MA=DEFI_MATERIAU (ELAS_FO=_F (E=E_F, NU=NU_F),,);
```

```
CM=AFFE_MATERIAU (MAILLAGE=M,
```

```
AFFE=_F (TOUT= “YES”, MATER= MA),
```

```
AFFE_VARC=_F (NOM_VARC=' NEUT1', CHAMP_GD=CHYOUNG),
```

```
)
```

**: 3/6**

### **3 Operands**

#### **3.1 Word**

**key**

**HIST\_EXP**

**HIST\_EXP**

**=**

**An occurrence of the key word factor HIST\_EXP makes it possible to define the ferrite evolutions, pearlite and bainite associated with a thermal history with cooling and conditions with austenitization data.**

#### **3.1.1 Operand**

**VALE**

**VALE = lval**

**List values defining the austenitization, the thermal history (T T) and ferrite evolutions, pearlite and bainite.**

**The first value is the value of derived from the function (T T) (i.e. the speed of cooling) when T is worth 700°C.**

**The second value is the size of grain (i.e. their diameter) resulting from the conditions of austenitization associated with the TRC.**

**The 6 following values define the thermal history between AR3 and TMF (temperature of beginning of decomposition of austenite in “quasi-static” cooling and temperature of end of martensitic transformation respectively). These values are the respective coefficients of students'rag processions of degree 0 to 5 such as the polynomial of a nature 5 thus built either the interpolation enters**

**AR3 and TMF within the meaning of least squares of the function (F)**

**T deduced from the thermal history and such as:**

(  
*F*)  
 $T = \ln (T (T))$

*If the experimental thermal history to define is a function closely connected of time (i.e. where the speed of cooling is constant) one will inform these six values like all equal to zero.*

*The following values (necessarily by group of 4) define the respective proportions of ferrite, pearlite and bainite present at a temperature given for the thermal history experimental defined by the first 8 values.*

*The ferritic, perlitic and bainitic transformations associated a thermal history are defined by the whole of the final proportions of each phase (final Z1, final Z2, Z3 final) and corresponding temperatures, for each transformation with:*

- *the temperature to which the transformation begins,*
- *the temperature to which 1% of new phase are formed,*
- *the temperature to which Zfinal 1% of new phase is formed,*
- *the temperature to which the transformation is finished (with Zfinal of formed phase).*

#### 3.2.1 Operand

##### **THRESHOLD**

##### **THRESHOLD**

= zS,

**Z**

*is the quantity of austenite transformed into on this side which  $ms$  is*

**S**

*invariant.*

#### 3.2.2 Operand

##### **AKM**

**AKM**

= akm,

*akm is the factor of proportionality between the reduction in temperature  $ms$  and quantity of transformed austenite ( $Z + Z + Z$  1 2 3 ).*

### **3.2.3 Operand BKM**

**BKM**  
**=  $bkm$ ,**

*bkm is the ordinate at the origin of the equation closely connected connecting the reduction in  $ms$  to quantity of transformed austenite.*

### **3.2.4 Operand TPLM**

**TPLM**  
**=**  
 **$V_c$ ,**

*$V_c$  is the speed of cooling with  $700^\circ\text{C}$  of the experimental history more slow, which makes it possible to form a little martensite.*

*These four key words define the values of the sizes THRESHOLD, AKM, BKM intervening in law of evolution of  $ms$  that one supposes independent of the size of grain.*

## **3.3 Word**

**key**  
**GRAIN\_AUST**

*Allows to define the influence of the size of grain on the metallurgical transformations in cooling defined by the diagram  $trc$ .*

### **3.3.1 Operand DREF**

**DREF =**  
 **$C$ ,**

*$C$  is the size of grain (i.e. its diameter) associated the diagram defined under the key word factor HIST\_EXP.*

### **3.3.2 Operand**

**With**

**With =**

**has**

**,**

*A is a parameter material which makes it possible to characterize the effect of the size of grain on diagram TRC of a steel (cf [R4.04.01]).*

*: 3/4*

*3 Operands*

### **3.1 Word**

*key*

**PLAN**

**PLAN**

:

*An occurrence of the key word **PLANE** factor makes it possible to lay down a crystallographic orientation in  
to leave the data:*

.

*of the three nautical angles laying down the orientation of the crystal compared to the reference mark total,*

.

*and of the proportion of the crystals of this orientation.*

#### **3.1.1 Operand**

**ANGL\_NAUT**

**ANGL\_NAUT: a1i, a2i, a3i**

*Defines the three nautical angles compared to the total reference mark for the ième orientation crystallographic. This is to be as many repeated once as of orientations present.*

*The maximum number of orientation is fixed at 40 in the source.*

#### **3.1.2 Operand**

**PROPORTION**

**PROPORTION: vali**

*The proportion of the crystals defines, of which orientation laid down above, compared to the whole of*

*crystals. This is to be repeated of as many time as of orientations present. The sum of well informed proportions must be equal to 1.*

### **3.2 Word**

*key*

**SYST\_GLISSEMENT**

**SYST\_GLISSEMENT**

:

*The key word factor **SYST\_GLISSEMENT** makes it possible to define the whole of the plans and the directions*

*of slip.*

***Currently, only the structures of the Cubiques type to Centered Faces are possible. That mean, that SYST\_GLISSEMENT must necessarily define four slip surfaces and three directions of slip for each one of these plans.***

*In fact, one directly defines the whole of all the directions of slip (thus 12 on the whole in the case CFC) and, for each directions of slip, one defines (by his normal vector) it slip surface which is associated for him (either 12 also in case CFC).*

*The complete syntax of SYST\_GLISSEMENT is thus necessarily, for a structure CFC:*

*SYST\_GLISSEMENT =*

*(*

*NR = (1. , 1. , 1. , 1. , 1. , 1. , -1. , -1. , -1. , -1. , -1. , -1.),*

*L = (- 1. , 0. , -1. , -1. , 0. , 1. , 0. , 1. , 1. , -1. , 1. , 0.)*

*)*

*(*

*NR = (1. , 1. , 1. , -1. , -1. , -1. , 1. , 1. , 1. , -1. , -1. , -1.),*

*L = (0. , -1. , 1. , 0. , 1. , 1. , -1. , 1. , 0. , 1. , 0. , 1.)*

*)*

*(*

*NR = (1. , 1. , 1. , 1. , 1. , 1. , 1. , 1. , 1. , 1. , 1. , 1.),*

$L = (1, 1, 0, 1, 1, 0, 1, 0, 1, 0, 1, 1)$

)

*One specifies however below the general standard of the operands NR and L.*

***Operator DEFI\_COMPOR***

## **1 Goal**

**To define the behavior of a monocrystal or a polycrystal, while allowing the user to choose them components of the single-crystal law of behavior. One gives, according to this definition, only its name of the crystallographic structure, knowing that directions of the systems of slip of each family of systems of slip are defined once for all in the source. behavior is defined in an external way with STAT\_NON\_LINE.**

**The structure of produced data contains names of systems of slip, associated names material parameters, for each behavior of monocrystal. Names of the systems of slip refer to internal objects with the code specifying for each one the orientations of slip surfaces.**

***3 Operands***

***3.1 Word***  
***key***  
***MONOCRYSTAL***

*An occurrence of the key word factor MONOCRYSTAL makes it possible to define a law of behavior elastoviscoplastic single-crystal. This is to be repeated once as many as one has laws of behavior single-crystal different [R5.03.11].*

### **3.1.1 Operand MATER**

*The name of the SD material defines used for the monocrystal. This operand makes it possible to check that parameters associated with the behaviors chosen under the key words FLOW, ECRO\_ISOT, ECRO\_CINE and ELAS exist well in material.*

### **3.1.2 Operand FLOW**

*The viscoplastic type of flow used in the definition of the law of behavior defines MONOCRYSTAL. This is to be chosen among: ECOU\_VISC1, ECOU\_VISC2, ECOU\_VISC3.*

### **3.1.3 Operand ECRO\_ISOT**

*The isotropic type of work hardening used in the definition of the law of behavior defines MONOCRYSTAL. This is to be chosen among: ECRO\_ISOT1 or ECRO\_ISOT2.*

### **3.1.4 Operand ECRO\_CINE**

*The kinematic type of work hardening used in the definition of the law of behavior defines MONOCRYSTAL. This is to be chosen among: ECRO\_CINE1 or ECRO\_CINE2.*

### **3.1.5 Operand ELAS**

*The type of the elastic behavior used in the definition of the law of behavior defines MONOCRYSTAL. This is to be chosen among: ELAS or ELAS\_ORTH.*

### **3.1.6 Operand FAMI\_SYST\_G LIS**

*The surname of the systems of slip defines on which one defined the law of behavior MONOCRYSTAL. Orientations of the normals in the slip surfaces and of directions of slip are calculated automatically by the code starting from the name of family.*

*This one is to be chosen among: BASAL, PRISMATIC, OCTAHEDRAL, PYRAMIDAL1, PYRAMIDAL2,*

## ***CUBIQUE1, CUBIQUE2, STIRRING, JOINT\_GRAIN, RL.***

### ***3.2 Word***

***key***

***POLYCRYSTAL***

***An occurrence of the key word factor POLYCRYSTAL makes it possible to define a phase of the behavior***

***polycrystalline, starting from the data of a single-crystal behavior, voluminal fraction of this phase, and of the orientation of this phase. This is to be repeated once as many as one has different single-crystal phases. Moreover, one rule of localization, commune to all them phases, is defined by the key word LOCALIZATION [R5.03.11].***

#### ***3.2.1 Operand***

***MONOCRYSTAL***

***The name of the SD compor defining defines the monocrystal.***

***J.M. PROIX, T. KANIT Key***

***:***

***U4.43.06-A Page***

***: 4/6***

#### ***3.2.2 Operand***

***FRAC\_VOL***

***The voluminal fraction of the phase in progress defines. The sum of the whole of the values of fvol must be equal to 1.***

#### ***3.2.3 Operand***

## ***ANGL\_REP***

*Defines the 3 nautical angles (provided in degrees) which make it possible to direct the monocrystal corresponding to the phase defined by the current occurrence of POLYCRYSTAL. For more specified on the nautical angles, to consult the documentation of AFFE\_CARA\_ELEM [U4.42.01].*

### ***3.3 Key word***

#### ***LOCALIZATION***

*The name of the rule of localization used for the polycrystal defines.*

#### ***3.3.1 Operands***

##### ***DL and DA***

*If the rule of localization is "BETA", two real parameters should be provided: dl and da.*

### ***3.4 Examples***

*The following example corresponds to a traditional use of MONOCRYSTAL. It results from the test SSNV171B:*

***ACIER=DEFI\_MATERIAU (ELAS=\_F (E=145200.0,***

***NU=0.3,)***

***ECOUC\_VISC2=\_F (N=10.0,***

```

K=40.0,
C=1.0,
D=36.68,
A=10.0,),
ECRO_ISOT2=_F (R_0=75.5,
Q1=9.77,
B1=19.34,
H=0.5,
Q2=-33.27,
B2=5.345,),
ECRO_CINE1=_F (D=36.68,));

```

```

COMPORT=DEFI_COMPOR (MONOCRISTAL= (_F (MATER=ACIER,
ECOULEMENT=' ECOU_VISC2',
ECRO_ISOT=' ECRO_ISOT2',
ECRO_CINE=' ECRO_CINE1',
ELAS=' ELAS',
FAMI_SYST_G LIS=' OCTAEDRIQUE',),),);

```

The following example, implementing POLYCRYSTAL, results from test SSNV125:

```

MATPOLY=DEFI_MATERIAU (ELAS=_F (E=192500.0,
NU=0.3,),
ECOULEMENT=_F (N=10.0,

### **3 General information**

**Possible error messages related to order** *AFFE\_CHAR\_MECA*

**It happens sometimes that a mechanical ordering of calculation** (*MECA\_STATIQUE*, *STAT\_NON\_LINE*,...)

**stop in fatal error during the calculation of the second elementary members due to the loadings defined in the** *AFFE\_CHAR\_MECA\_xx* **orders. When the code stops during these calculations elementary, important information of the error message is the name of the option of calculation asked by the code.**

**The name of this option is in general unknown to the user and it is thus difficult for him to include/ understand the message.**

**In the table below, one gives in with respect to the names of the options of calculation, the name of order and key word factor which make it possible to activate this option.**

**Elementary option of calculation**

## **4 Operands**

### **4.1**

#### **General information on the operands**

##### **4.1.1 Two categories of operands**

*The operands under a key word factor are of two forms:*

.

*operands specifying the geometrical entities on which are affected them loadings (key words GROUP\_NO, GROUP\_MA, etc...). The arguments of these operands are identical for the two operators,*

.

*operands specifying the affected values (DX, DY, etc...). Significance of these operands is the same one for the two operators. The arguments of these operands are all the real type for operator AFFE\_CHAR\_MECA and of the function type (created in particular by one of operators DEFI\_FONCTION, DEFI\_NAPPE or DEFI\_CONSTANTE) for operator AFFE\_CHAR\_MECA\_F.*

*This is true near with an exception: the argument of COEF\_MULT for the key word factor LIAISON\_DDL in AFFE\_CHAR\_MECA\_F is obligatorily of real type.*

*We will thus not distinguish in this document, except mention express of the opposite, both operators AFFE\_CHAR\_MECA and AFFE\_CHAR\_MECA\_F.*

##### **4.1.2 Designation of the topological entities of assignment of the loadings**

*In a general way, the entities on which values must be affected are defined:*

*.  
by node and in this case:*

*- is  
by  
the operand  
GROUP\_NO allowing to introduce a list of groups of nodes:  
let us note that in certain cases a group of node must contain one node,  
-  
maybe by the operand NODE allowing to introduce a list of nodes.*

*.  
by mesh and in this case:*

*- is  
by  
GROUP\_MA allowing to introduce a list of groups of meshes,  
- is  
by  
NET allowing to introduce a list of meshes.*

#### *4.1.3 Regulate of overload*

*To define the field of assignment most simply possible, the rule of overload is used defined in the document " Règles of overload " [U1.03.00]:  
it is the last assignment which precedes.*

#### *4.1.4 Structural elements, continuous mediums*

*For the assignment of the loadings distributed on the elements with average layer (plate - hull) or with  
average fibre (beam, cable, bar) the key words factors are distinct from those used for  
continuous mediums.*

***4.1.5 Normals and tangents with the meshes***

***Normals:***

***.***

***SEG2 or SEG3 in 2D (coordinated defined by COOR\_2D in the file of grid in format Aster). Normal N is such as (N, T) form a direct reference mark, T being carried by segment directed by the first two nodes of the segment.***

***2***

***T***

***1***

***N***

***.***

***QUAD4,..., QUAD9, TRIA3, TRIA6 in 3D (coordinated defined by COOR\_3D in the file of grid to the format Aster). The orientation of normal N is that corresponding to the direction direct of the description of the mesh.***

***N***

***N***

***3***

***4***

***3***

***1***

***2***

***1***

***2***

***Tangents:***

*Can be specified only if the mesh is of type SEG2 or SEG3 in 2D. The tangent is that defined by the segment directed by its first two nodes.*

*2  
1  
T*

*If DNOR (or DTAN) are specified, the normal (or the tangent) on a node is the average of normals or of the tangents of the meshes which have this joint node (except for the elements quadratic curves where the normal is correctly calculated in any point)*

*N  
N  
N*

*4.2 Operand  
MODEL*

*MODELE= Mo,*

**Concept produced by operator AFFE\_MODELE where the types of affected finite elements are defined on the grid.**

#### **4.3 Operand VERI\_NORM**

```
/ VERI_NORM=/“YES”  
[DEFECT]  
/  
“NOT”
```

**Checking of the orientation of the normals to the surface in 3D and linear meshes in 2D. If a normal is not outgoing, there is emission of an error message.**

#### **4.4 Operand LIAISON\_XFEM (AFFE\_CHAR\_MECA only)**

```
/ LIAISON_XFEM=  
“YES”,
```

**During a calculation with method X-FEM [R7.02.12], it is necessary to create a load additional to cancel some ddl's nouveau riches. It is thus necessary imperatively to indicate LIAISON\_XFEM=' OUI' in this specific charge for any calculation X-FEM, as on the following example:**

```
chxfem  
= AFFE_CHAR_MECA (MODEL  
= model,  
LIAISON_XFEM = “YES”,  
)
```

#### **4.5 Operand TEMP\_CALCULEE (AFFE\_CHAR\_MECA only)**

```
/ TEMP_CALCULEE= temple,
```

**Concept produced by a linear thermal calculation or not linear (THER\_LINEAIRE [U4.54.01], THER\_NON\_LINE [U4.54.02]) or created starting from values of temperatures affected by order CREA\_CHAMP [U4.72.04] key word AFFE or starting from order CREA\_RESU [U4.44.12]. If the concept temple is of cham\_no\_TEMP\_R type then the thermal loading will be supposed to be constant in time. If it is of type evol\_ther, the possible prolongations to the terminals of transitory calculation will be supposed to be constant.**

#### **4.6 Operand**

**HYDR\_CALCULEE (AFFE\_CHAR\_MECA only)**

**/ HYDR\_CALCULEE**

**=**

**hydr,**

**Concept produced by a nonlinear thermal calculation (THER\_NON\_LINE [U4.54.02]) gathering fields of hydration and temperature in a concept of the evol\_ther type.**

#### **4.7 Operand**

**SECH\_CALCULEE (AFFE\_CHAR\_MECA only)**

**/ SECH\_CALCULEE**

**=**

**sech,**

**Concept produced by a nonlinear thermal calculation (THER\_NON\_LINE [U4.54.02]) gathering fields of drying.**

**This concept can be either of evol\_ther type, or of cham\_no\_TEMP\_R type (if the loading is constant in time), that is to say of carte\_temp\_R type (if the loading is constant spaces some and in time), that is to say of carte\_temp\_F type (loading function of space).**

**Author (S):**

**X. DESROCHES Key**

**:**

**U4.44.01-II Page**

**: 14/92**

#### **4.8 Operand**

**EPSA\_CALCULEE (AFFE\_CHAR\_MECA only)**

**/EPSA\_CALCULEE**

=

*epsa,*

*Anelastic deformations resulting from external software (Cyrano3 Code for example) and converted into result of the evol\_noli type by order LIRE\_RESU [U7.02.01] option “EPSA\_ELNO”. This loading is taken into account by STAT\_NON\_LINE [U4.51.03].*

#### **4.9 Operand**

**EVOL\_CHAR (AFFE\_CHAR\_MECA only)**

**/EVOL\_CHAR**

= *evch,*

*Evolutionary loadings in the time of the type “evol\_char” [U5.01.17] produced by LIRE\_RESU [U7.02.01] and containing fields of pressure, densities of voluminal force in 2D or 3D and densities of surface force in 2D or 3D.*

#### **4.10 Operand**

**GRAVITY (AFFE\_CHAR\_MECA only)**

**/GRAVITY = (G, ap, LP, CP),**

*Acceleration and direction of gravity. The loading which results from it is form:*

*where*

*is the total Cartesian reference mark.*

*is the definite density like characteristic of material (see operators DEFI\_MATERIAU [U4.43.01] and AFFE\_MATERIAU [U4.43.03]).*

#### **4.11 Operand**

**ROTATION (AFFE\_CHAR\_MECA only)**

**/ROTATION**

= (*, rear, Br, Cr*),

*Number of revolutions and direction of the vector rotation which leads to:*

*The loading which results from it is: (OM) where is the origin of the co-ordinates and a point running of the structure with definite density like characteristic of material (see operators DEFI\_MATERIAU [U4.43.01] and AFFE\_MATERIAU [U4.43.03]).*

***CENTER = (X, y, Z),***

***If the center is not the origin, one can specify his co-ordinates (X, y, Z).***

***Important remark:***

***One can vary in time the number of revolutions by breaking up the rotation in way multiplicative between space loading and evolution in time***

***, then in***

***multiplying the LOAD by a multiplying function (key word FONC\_MULT) in calculation transient (DYNA\_TRAN\_MODAL, DYNA\_LINE\_TRAN, DYNA\_NON\_LINE). However, it is appropriate to pay attention: the loading [(OM)] being proportional squared number of revolutions,***

***, it is necessary to affect the square of the evolution in time,***

***, behind FONC\_MULT.***

: 21/92

#### **4.14.4 Precautions of use**

##### **4.14.4.1 Components in rotation**

The components of displacement in rotation *DRX*, *DRY*, *DRZ* can intervene only in combinations **only** assigned to nodes which belong to **discrete** elements of translation-rotation, of **beam** or **hull** (see *DDL\_IMPO*: cf [§4.10]).

##### **Linear 4.14.4.2 Relation between the ddl of the same node**

In this particular case, one will as many repeat behind the key word *NODE* the name of the node time as there is

of *ddl* in the relation. Example: to impose on the *N1* node, one will write:

*LIAISON\_DDL* = *\_F* (*NODE* = ("N1", "N1"),

*DDL* = ("DX", "DY"),

*COEF\_MULT*

=

(1.,

-1.),

*COEF\_IMPO*

=  
0.,

)

#### ***Linear 4.14.4.3 Relation between groups of nodes***

*It is important to note that to an occurrence of the key word factor LIAISON\_DDL corresponds one and one only linear relation.*

*If one wants to impose the same relation between 2 groups of nodes GRN01 and GRN02 (even displacement node with node for example) **one cannot write:***

*LIAISON\_DDL = \_F (GROUP\_NO = ("GRN01", "GRN02"),*

*DDL = ("DX" "DX"),*

*COEF\_MULT*

=

*(1.*

,

*-1.),*

*COEF\_IMPO*

=

*0.,*

)

*This writing has direction only if GRN01 and GRN02 contain each one one node. It will be necessary*

*in the case above to clarify each linear relation, node by node, or to use LIAISON\_GROUP [§4.14] which makes it possible to condense the writing of same linear relations between two groups of nodes in opposite.*

#### ***4.16.5 Determination of the couples of nodes in opposite***

***It is in the same way made that in AFFE\_CHAR\_THER.***

***Initially, one draws up the two lists of nodes to be put in opposite (IE to be paired), for each occurrence of the key word factor LIAISON\_GROUP:***

.

***for key words GROUP\_NO\_1 and GROUP\_NO\_2, they are the nodes constituting them groups of nodes,***

.

***for key words GROUP\_MA\_1 and GROUP\_MA\_2, they are the nodes of the meshes setting up the groups of meshes.***

***The redundancies being eliminated, the two lists of nodes obtained must have the same one length.***

***The determination of the couples of nodes in opposite is done in several stages:***

.

***for each N1 node of the first list, one seeks the node image  $N2 = F(N1)$  of second list. If  $F$  is not injective (a node  $N2$  is the image of two distinct nodes  $N1$  and  $N1'$ ), the error message according to is emitted:***

***<F> <AFFE\_CHAR\_MECA> <PACOAP> CONFLICT IN WITH RESPECT TO THE NODES***

***The NODE N2 EAST IT WITH RESPECT TO the NODES N1 AND N1'***

.

***for each node N2 of the second list, one seeks the node N1 image =  $G(N2)$  of***

*first list. If  $G$  is not injective (a  $N1$  node of two distinct nodes  $N2$  is the image and  $N2'$ ), the error message according to is emitted:*

**<F> <AFFE\_CHAR\_MECA> <PACOAP> CONFLICT IN WITH RESPECT TO THE NODES**

**The NODE  $N1$  EAST IT WITH RESPECT TO the NODES  $N2$  AND  $N2'$**

*it is checked that  $G = f1$ , i.e. the couples obtained by the stages has) and b) are them same (one wants to have a bijection  $F$  between the two lists of nodes). If  $F$  is not surjective, the error message according to is transmitted:*

**<F> <AFFE\_CHAR\_MECA> <PACOAP> CONFLICT IN OPPOSITE GENERATE**

**SUCCESSIVELY FROM LISTS LIST1 AND LIST2**

**The NODE OF the FIRST  $N1$  LIST IS NOT the IMAGE Of ANY NODE BY CORRESPONDENCE OPPOSITE**

**:**

**U4.44.01-II Page**

**: 28/92**

*For a node NR given, one calls node image F (NR) the node of the other list of nodes which carry out the minimum of the distance with NR. to facilitate pairing, in particular in the case of particular geometries (where borders 1 and 2 could “almost” result one from the other by the composition of a translation and a rotation), one makes it possible to do one virtual geometrical transformation of the first group of nodes (translation and rotation before to calculate distances (key words TRAN, CENTER and ANGL\_NAUT).*

*For each occurrence of the key word factor LIAISON\_GROUP, one builds the list thus of new couples in opposite. When all the occurrences were swept, list is removed couples in double.*

*Note:*

*In the couples of nodes in opposite, the order of the nodes is important. If for first occurrence of LIAISON\_GROUP, a node NR belonged to the first group of nodes and a node M with the second group of node, and that for the second occurrence LIAISON\_GROUP, it is the reverse, one will obtain with the exit pairing the couples (NR, M) and (M, NR). They will not be eliminated during detection of the redundancies; by against, the matrix obtained will be singular. Thus, one advises to keep same logic during the description of the edges in opposite.*

*: 29/92*

*4.17 Key word*

*LIAISON\_MAIL*

*4.17.1 Drank*

***Key word factor usable to define linear relations allowing “to restick” two “edges” of one structure.***

***The characteristic of this key word (compared to LIAISON\_GROUP for example) is to make it possible to bind displacements of unconstrained nodes on the grid. Grids of FACE 1 and FACE 2 can be incompatible.***

***Examples:***

***) a condition of periodicity has (study of a cell of homogenisation)***

***FACE 1  
FACE 2***

***b) a cyclic condition of repetitivity***

***FACE 1  
FACE 2***

***c) a condition of simple sticking together***

***FACE 1 FACE 2***

***In the continuation of this paragraph, one will speak about the face “slave” (FACE 2) and about the face “Master” (FACE 1).***

***The “sticking together” of the 2 faces will be done by writing of linear relations between the ddls of the 2 faces.***

***Displacements of the nodes of the face slave will be connected to displacements of their projections on the face Master. For each node of the face slave, one will write 2 (in 2D) or 3 (in 3D) relations linear.***

***If FACE 1 and FACE 2 are not geometrically confused but that there is a isometry (rotation + translation) between the two, the user must define this isometry (that which transforms FACE 2 opposite 1).***

***An application of this functionality is for example the sticking together of a formed grid of elements linear (P1) on another quadratic grid (P2). In this case it is rather advised to choose like face “slave” the quadratic face.***

### ***4.17.3 Operands***

#### ***4.17.3.1 GROUP\_NO\_ESCL/NOEUD\_ESCL/GROUP\_MA\_ESCL/MAILLE\_ESCL***

*These key words make it possible to define the whole of the nodes of the face slave. One takes all them nodes specified by key words **GROUP\_NO\_ESCL** and **NOEUD\_ESCL** more all nodes carried by meshes specified by key words **GROUP\_MA\_ESCL** and **MAILLE\_ESCL**.*

#### ***Note:***

*When one wants to restick only normal displacements of the faces (cf key words **DDL\_MAIT** and **DDL\_ESCL**), it is necessary to be able to determine the normal direction of the faces. The normal direction is calculated on the face slave. It is thus necessary in this case to use key words **GROUP\_MA\_ESCL** and **MAILLE\_ESCL** with meshes of the type “facets”.*

#### ***4.17.3.2 GROUP\_MA\_MAIT/MAILLE\_MAIT***

*These key words make it possible to define the whole of the meshes where they with respect to the nodes will be sought face slave.*

**Caution:**

*In 3D, one should not give meshes of surface, but the voluminal meshes adjacent with face. The specified meshes are “candidates” for the research of the points opposite. One can in giving too much, that is not awkward.*

*In the same way, in 2D, the meshes “Masters” must be surface (QUAD, SORTED) and nonlinear*

**4.17.3.3 CENTERS/ANGL\_NAUT/TRAN**

*These key words make it possible to define the geometrical transformation (rotation and/or translation) allowing to pass from the face main slave to the face.*

*If these key words miss, it is that the geometrical transformation is “the identity” i.e. the faces Master and slave are geometrically confused.*

*It should be noted that the program carries out initially rotation and then the translation. Caution: the direction transformation is slave --> main.*

**4.17.3.4 DDL\_MAIT/DDL\_ESCL**

*If one wants to restick only normal displacements with the faces, it is necessary to specify:*

*DDL\_MAIT = “DNOR”*

*DDL\_ESCL = “DNOR”*

**Note:**

*The normal direction is calculated on the face slave (it is necessary to give meshes of facet). This normal direction is transformed by the possible rotation of the geometrical transformation for to determine the normal direction on the face Master.*

: 31/92

#### **4.17.3.5 ELIM\_MULT= “YES”/“NOT” (defect)**

*This key word is used to solve the difficulty which can arise when several surfaces are restuck adjacent slaves (i.e who have one or more common nodes).*

*Let us imagine for example that one writes (in 2D):*

```
LIAISON_MAIL= (  
_F (GROUP_MA_ESCL=' LIGNE_AB', GROUP_MAIT=...)  
_F (GROUP_MA_ESCL=' LIGNE_BC', GROUP_MAIT=...)
```

*If the user forces ELIM\_MULT=' OUI', the program will treat each occurrence of LIAISON\_MAIL in way independent. The node B, pertaining to LIGNE\_AB and LIGNE\_BC will be eliminated 2 times and it*

*is unfortunately probable that calculation will stop during the factorization of the matrix with message “Pivot almost no one...” because the linear relations generated by LIAISON\_MAILLE are redundant.*

*Most of the time, defect (ELIM\_MULT=' NON') is the good choice. The only case where the user could use ELIM\_MULT=' OUI' is that of the use of key word DDL\_ESCL=' DNOR' bus if in the 2 occurrences, the normals “slaves” are not the same ones, elimination is not redundant.*

#### ***4.18 Key word***

***LIAISON\_CYCL***

##### ***4.18.1 Drank***

***Key word factor usable to define the linear relations allowing to impose conditions of cyclic symmetry with taking into account of a dephasing. It is mainly dedicated to being used in the restrictive framework of dynamic calculation with cyclic symmetry.***

***The characteristic of this key word (with the image of LIAISON\_MAIL) is to make it possible to bind displacements unconstrained nodes on the grid. The grids of FACE G and FACE D can be incompatible.***

***The cyclic condition of repetitivity applied within the framework of dynamics is based on method of duplication of grid. The operator thus leaves on the postulate that the initial grid one sector is duplicated in two grids identical to the image of the following figure.***

***In the continuation of this paragraph, one will speak about the face “slave” and the face “Master”. The “sticking together” of the 2 faces will be done by writing of linear relations between the ddls of the 2 faces.***

***Displacements of the nodes of the face slave will be connected to displacements of their projections on the face Master. For each node of the face slave, one will write 2 (in 2D) or 3 (in 3D) relations linear.***

***If FACE G and FACE D are not geometrically confused but that there is a isometry (rotation + translation) between the two, the user must define this isometry (that which transforms***

**FACE G opposite D).**

**Note:**

**An application of this functionality is for example the sticking together of a formed grid linear elements (P1) on another quadratic grid (P2). In this case it is rather advised to choose like face “slave” the quadratic face.**

**The expression of the cyclic condition of symmetry for a dephasing AND element given and in considering G as the interface slave is as follows:**

**X. DESROCHES Key**

**:**

**U4.44.01-II Page**

**: 34/92**

### **4.20.3 GROUP\_MA\_MAIT2/MAILLE\_MAIT2**

*These key words make it possible to define the whole of the meshes of 1 (or 2) where one will seek opposite nodes of the face slave of grid 1 or 2.*

**Caution:**

*In 3D, one should not give meshes of surface, but the voluminal meshes adjacent with face. The specified meshes are “candidates” for the research of the points opposite. One can in giving too much, that is not awkward.*

*In the same way, in 2D, the meshes “Masters” must be surface (QUAD, SORTED) and nonlinear*

#### **4.20.4 CENTER/ANGL\_NAUT/TRAN**

*These key words make it possible to define the geometrical transformation (rotation and/or translation) allowing to pass from the face main slave to the face.*

*If these key words miss, it is that the geometrical transformation is “the identity” i.e. the faces Master and slave are geometrically confused.*

*It should be noted that the program carries out initially rotation and then the translation. Caution: the direction transformation is slave --> main.*

#### **4.20.5 COEF\_MAIT1/COEF\_MAIT2/COEF\_ESCL**

*These key words make it possible to define the coefficients of the linear relation to apply, in the case of cyclic symmetry it acts of the cosine and sines of the angle of dephasing AND element considered. These coefficients must thus be coherent with the definition of the interfaces Masters and slaves. coefficient COEF\_ESCL makes it possible to pass a coefficient in front of the dds slaves.*

*For example:*

#### **4.20.6 DDL\_MAIT/DDL\_ESCL**

*If one wants to restick only normal displacements with the faces, it is necessary to specify:*

*DDL\_MAIT = “DNOR”*

*DDL\_ESCL = “DNOR”*

*Note:*

*The normal direction is calculated on the face slave (it is necessary to give meshes of facet). This normal direction is transformed by the possible rotation of the geometrical transformation for to determine the normal direction on the face Master.*

***:***

***U4.44.01-II Page***

***: 35/92***

***4.21 Key word***

***CONTACT***

***4.21.1 Drank***

***Key word factor usable to describe the zones subjected to conditions of unilateral contact with or without friction. These zones (for each occurrence of the key word factor), include/understand each one two surfaces being able to come into contact which are described by the data of the meshes which them constitute.***

***The sets of meshes potentially in contact are: surface and linear in dimension 3 (QUAD9, QUAD8, QUAD4 and TRIA7, TRIA6, TRIA3 and SEG2, SEG3), linear and concentrates in dimension 2 (SEG2, SEG3 and POI1).***

***Caution:***

***In dimension 3, treatment of the contact with quadratic surface meshes (QUAD8 and TRIA6 or QUAD9 and TRIA7 associated with modeling COQUE\_3D) require to bind them nodes mediums on the sides at the tops in order to have correct results. This operation is made automatically in the Code. Nevertheless, for calculations 3D mediums continuous with quadratic elements, the use of elements HEXA27 (with faces QUAD9) is strongly advised.***

***There is a modified version of projection with quadratic surface meshes of which the polynomials are incomplete. This projection (usable with HEXA20 and QUAD8) ensure has minimum that the reactions of contact are coherent. One activates it via the option PROJECTION = "QUADRATIC".***

***The studied structures can undergo great slips one compared to the other. This formulation, nodal contact or node-facet in reactualized geometry, with reactualization of pairing controlled by the user, is described in the document [R5.03.50] and is established in operators STAT\_NON\_LINE [U4.51.03] and DYNA\_NON\_LINE [U4.53.01].***

*Before making a calculation with contact using the key word CONTACT, it is essential to have read reference material [R5.03.50] and notes it HI-75/97/034/A of councils to the users, who clarify the role of the majority of the key words described below and give the precautions of use.*

*It is also recommended to consult the documentation of use of the contact [U2.04.04].*

#### **4.21.2 Syntax (AFFE\_CHAR\_MECA (\_F))**

*There are several methods to deal with the problems of contact/friction. One separated below operands suitable for each one.*

### 4.21.3 Operands

**MAILLE\_MAIT** or **GROUP\_MA\_MAIT**,

**MAILLE\_ESCL** or

**GROUP\_MA\_ESCL**

*The user provides the list of the potential meshes of contact of surface 1 (MAILLE\_MAIT or GROUP\_MA\_MAIT) and of surface 2 (MAILLE\_ESCL or GROUP\_MA\_ESCL). These meshes must be surface or linear in dimension 3 (QUAD9, QUAD8, QUAD4 and TRIA7, TRIA6, TRIA3 and SEG2, SEG3), linear and concentrates in dimension 2 (SEG2, SEG3 and POI1). The number of meshes and of nodes of two surfaces can be different.*

#### **Caution:**

*It is important to check that the connectivity of these meshes is such as the **normal is outgoing with the structure** (with this intention, to see MODI\_MAILLAGE key word ORIE\_PEAU\_2D, ORIE\_PEAU\_3D or ORIE\_NORM\_COQU [U4.23.04]). In addition, it should be made sure that the structures “do not hold that by the contact” (in particular in the case of a loading in imposed force): movements of rigid body must be blocked by boundary conditions suitable. One good way of checking it is to carry out a calculation with operator STAT\_NON\_LINE without to take into account the contact.*

*Subsequently, the master-slave concept will be used: nodes of surface slave cannot “penetrate” in the facets (or the nodes) of surface Master. In the case of the pairing of the type “MAIT\_ESCL”, surface Master is that defined by “MAILLE\_MAIT” or*

*“GROUP\_MA\_MAIT” (for councils on the main choice of surface, to refer to the note HI-75/97/034/A). In the case of the pairing of the “NODAL” type, surface Master is that which comprise the most nodes.*

**Note:**

*It is impossible to mix purely two-dimensional modelings (plane constraints, plane and axisymmetric deformations) with three-dimensional modelings. Surfaces Master and slave must be of comparable nature (2D/2D or 3D/3D). An error message you will stop in the contrary case:*

*<CFCRSD> MIXTURE 2D and 3D IN the CONTACT*

*Let us note that a beam, a plate or a hull are of dimension 3 and that it is thus possible to make contact poutre/3D or beam/plate.*

#### **4.21.4 Operands NOM\_CHAMP**

*This operand makes it possible to specify the nature of the field on which will carry the unilateral relations.*

*In mechanics, it is about the field of displacement (“DEPL”); in thermics, it is about the field of temperature (“TEMP”); in thermo-hydro-mechanics, it is about the field of displacement or of temperature or of pressure (“NEAR”, “PRE1” or “PRE2”). One can use fields PRE1, PRE2 to impose a condition of seepage in THM.*

#### **4.21.5 Operand PAIRING**

*Pairing can be nodal (“NODAL”) or node-facet (“MAIT\_ESCL”). For pairing nodal, one writes a relation of nonpenetration between a main node and a node slave, whereas for pairing node-facet, one writes this relation between a node slave and his projection on net main nearest (see [R5.03.50] for the details of the method of pairing).*

*Nodal pairing is disadvised because the method node-facet is more general and is the only one with to allow to take into account the great slips in a precise way.*

*Pairing “MAIT\_ESCL” has an alternative where one duplicates and one exchanges the roles of groups of meshes GROUP\_MA\_MAIT and GROUP\_MA\_ESCL. It is about pairing “MAIT\_ESCL\_SYME”. Nevertheless, its use is disadvised because it often leads to problems of convergence and tends on-to rigidify the contact.*

*In the cases of contact rigid or unilateral relations relating to the temperature or the pressure, pairing can also be useless: APPARIEMENT='NON' then is informed.*

*Instruction manual*

22/02/06

Author (S):

**X. DESROCHES** Key

:

U4.44.01-II Page

: 40/92

**4.21.6 Operand COEF\_IMPO/COEF\_MULT\_ESCL**

*These operands make possible a rigid contact of type  $COEF\_MULT\_2^* (v.N) = COEF\_IMPO$  where  $NR$  is the normal on the surface slave at the point where one measures field  $v$  (displacement, temperature or pressure). These operands are used with  $APPARIEMENT='NON'$  and key words  $GROUP\_MA\_2$  or  $MAILLE\_2$  only.*

**4.21.7 Operand PROJECTION**

*This operand indicates the type of functions of form used during the projection of a node slave on a mesh Master. The taking into account of the quadratic character of an element allows best to describe its geometry and to improve quality of the result.*

.

*In 2D, one uses either of the linear functions of form or of the functions of form quadratic.*

.

*In 3D, one uses that linear functions of form. Except for the elements  $HEXA20$  which can use a modified version of the functions of form, via the option  $PROJECTION='QUADRATIQUE'$ .*

**4.21.8 Operand NB\_RESOL**

*A number of simultaneous resolutions made during the treatment of the contact. To increase  $nb\_resol$  made to save time CPU but to lose place memory.  $nb\_resol = 10$  is a good compromise.*

**4.21.9 Operand SEEKS**

*To seek the mesh Master which will be paired with each node slave, one seeks initially its main node nearest, by a systematic loop on all the main nodes of the zone (“NOEUD\_BOUCLE”), that is to say by examining only the neighbors of the old main node nearest (“NOEUD\_VOISIN”): this last approach supposes small slips of a step of time with the other (not more than two meshes), but makes it possible to save computing time. Nevertheless, it can lead to non convergence, in which case it is necessary to resort to “NOEUD\_BOUCLE”.*

#### **4.21.10 Operand REAC\_GEOM**

*This operand indicates on which geometrical configuration the problem of contact is dealt with.*

*REAC\_GEOM=' SANS': one works on the initial geometry.*

*REAC\_GEOM=' CONTROLE': if this option is indicated, the user must moreover indicate:*

*NB\_REAC\_GEOM=n: It is the number of geometrical reactualizations which will be carried out by step of load. We place at a step of load given.*

*- Value 1 indicates that with convergence, one reactualizes the geometry and one passes to the load according to.*

*- Value 2 indicates that to convergence, one does not pass to the step of load according to. One reactualizes the geometry and one reiterates until convergence.*

*- The value  $n > 2$  indicates that one makes  $N$  cycles reactualization geometrical-iterations until convergence.*

*REAC\_GEOM=' AUTO': one reactualizes the geometry i.e automatically the number of cycles reactualization geometrical-iterations until convergence is not fixed by advance but obeys an internal criterion of geometrical convergence.*

*Note:*

*IF you chose a reactualization not-automatic and that Aster detects the need for one geometrical reactualization, it will inform you by an alarm:*

**<CFCONV> REAC\_GEOM OF CONTACT HIGHER A 5%**

*With you to decide if this error of 5% is acceptable or not. It corresponds grosso-modo to a relative displacement of two surfaces of contact higher than 5% and thus a risk of error of pairing (the mesh was paired on a configuration which moved).*

:

U4.44.01-II Page

: 41/92

**4.21.11 Operands SANS\_NOEUD/SANS\_GROUP\_NO/SANS\_NOEUD\_QUAD**

*These operands make it possible to exclude from the nodes of the list of the nodes slaves, operation which is*

*recommended for nodes subjected to boundary conditions in the direction awaited of contact (embedding example).*

*The operand SANS\_NOEUD\_QUAD (which is worth “NOT” by defect) makes it possible to authorize or not the connection*

*linear realized automatically by the code in the case of quadratic meshes for the contact. This operand is useful in the case of redundancy between these linear constraints and certain conditions limits of the Dirichlet type. When the operand is worth “NOT”, although the nodes are excluded from the contact,*

*the nodes mediums of the quadratic meshes are always linearly related to the tops, which can to cause these interferences (null pivots). One can then use option SANS\_NOEUD\_QUAD=' OUI' to solve this conflict.*

**4.21.12 Operands DIST\_MAIT/DIST\_ESCL**

*These operands make it possible to take into account “holes” or “bumps” nonwith a grid, or the thickness of the hulls (the relations of contact are written between two average surfaces) for groups of meshes 1 (DIST\_MAIT) or 2 (DIST\_ESCL). One counts the distance positively in the direction of the outgoing normal to the structure (cf document [R5.03.50 § 3.3]). Sizes informed are either of the constants, or of the functions of the variables of space only.*

**4.21.13 Operand VECT\_NORM\_ESCL**

*This operand allows the contact between two nodes in a direction VECT\_NORM\_ESCL = (vx, vy, vz) given by the user. The contact is taken into account between meshes of the type POII and can be used only in the case of a nodal pairing. If this key word misses, the direction of*

*contact calculated at the time of the procedure of pairing is opposed to the normal Master.*

#### **4.21.14 NORMAL operand**

*This operand makes it possible to select a method of calculation of the normals according to the mesh Master considered (by defect or explicitly by the order: NORMAL = "MAIT") or according to one average enters the meshes Masters and slaves with the order: NORMAL = "MAIT\_ESCL".*

#### **4.21.15 Operand STOP\_SINGULIER**

*This operand makes it possible to decontaminate the fatal error appearing if the matrix of contact is singular by STOP\_SINGULIER = "NOT". One advises to use this operand only in 3D in the presence of quadratic meshes whose nodes mediums are related to the nodes tops.*

#### **4.21.16 Operand TOLE\_PROJ\_EXT**

*Under certain conditions, Aster detects contact between two surfaces whereas there is not. problem comes initially from an incorrect and imperfect definition of surfaces likely to enter in contact. Let us take the case of the contact in 2D (surfaces of contact are thus segments). Aster carries out a Re-projection on surface Master when a node slave is projected outwards surface Master:*

*slave*

*Master*

*A solution consists in prohibiting this Re-projection:*

*slave*

*Master*

***22/02/06***

***Author (S):***

***X. DESROCHES Key***

***:***

***U4.44.01-II Page***

***: 42/92***

***This solution does not take account of the borderline cases and can cause interpenetrations inopportune if ever the grid is not “optimal” (what is difficult to ensure within the framework great transformations). One thus chose an intermediate solution by limiting the extension surface Master at the time of the reprojection.***

***slave***

***Master***

***Re-projection***

***No Re-projection***

***(one is in the tolerance)***

***The limiting value of this Re-projection is fixed by the keyword “TOLE\_PROJ\_EXT” which takes for argument the value (adimensional) of the extension da the mesh Master in which one authorizes Re-projection. By defect, this value is fixed at 0.50. What means that any node slave projecting with more than 50% on the right or on the left (in the case of a segment) the length of the mesh***

***Master will not be reprojété. To prohibit Re-projection completely, it is enough to fix TOLE\_PROJ\_EXT with zero. This operator is valid in 2D and 3D (in this last case, it acts of extension of a surface mesh of contact).***

***4.21.17 Operand TOLE\_PROJ\_INT***

***In certain cases, projection causes undesirable oscillations between two limiting situations (mathematically, the unicity of the normal is not assured). There are then problems of***

*convergence, particularly when automatic geometrical reactualization is made (REAC\_GEOM=' AUTO'). The limiting value fixed by keyword "TOLE\_PROJ\_INT" makes it possible to regulate finely the detection of projection on the internal geometrical entities. This adjustment is reserved with the very pathological cases and exclusively when one uses surfaces of contact made up of QUAD4.*

#### **4.21.18 Operand ITER\_MULT\_MAXI**

*This operand makes it possible to fix the maximum number of iterations of contact/friction. The number internal iterations maximum Nmax is fixed by the following relation:*

$$N_{max} = ITER\_MULT\_MAXI \times Neslaves$$

*where Neslaves is the number of nodes slaves of the couple of contact. By defect, ITER\_MULT\_MAXI is fixed at 4, except for the method of the active constraints where the value is not modifiable and remains fixed at two (value resulting from a theoretical result of convergence).*

*If one exceeds the maximum number of iterations of contact/friction, one obtains the error message "Failure in the treatment of the contact". One can then try to refine the grid, to subdivide the step of time, or to change the value of ITER\_MULT\_MAXI.*

#### 4.21.19 Operands *VECT\_Y* and *VECT\_Z*

*For the discrete methods (LAGRANGIAN and PENALIZATION), operand VECT\_Y has two possible functions related to the contact with friction in 3D.*

*it makes it possible to define a local reference mark on the surface of an element, locates on which one*

*break up the displacement of the slipping nodes. The construction of this local dihedron is following: the first *V1* vector is obtained by orthogonal projection of *VECT\_Y* on surface element considered, second *V2* is obtained by vector product of *V1* with normal vector *NR*,*

*that is to say the block below whose face *SB* is blocked according to *y* and face *SF* is subjected to conditions of contact-friction. According to the line *L* can appear redundancies between blockings and conditions of friction in direction *Y*. the problem is insoluble (null pivots). One can raise these redundancies by informing *VECT\_Y* to (0, 1, 0), direction in which the redundancies appear. The problem can then be solved. This type of difficulty appears only with *METHOD* = "LAGRANGIAN".*

*Z*  
*SF*  
*y*  
*L*  
*X*  
*SB*

*This operand allows also the modeling of the contact between coplanar beams in 3D:*

*Are 2 beams in the *xOy* plan. *VECT\_Y* is the vector which, by vector product with tangent vector with the beam, gives the normal to be used. That is to say:*

$$VECT\_Y^T = NR$$

*T2*  
*Z*  
*y*  
*X*  
*T1*

*As here  $T1 = (1,0,0)$  and  $T2 = (-1,0,0)$ , with  $VECT\_Y = (0,0,1)$ , one obtains the normal wished for each beam:  $N1 = (0,1,0)$  and  $T2 = (0, -1,0)$ . Attention with the fact that all this is entirely related to the orientation of each beam.*

*For the method = "CONTINUES", these keywords allow the user to exclude from the directions from friction which is likely to enter in conflict with other boundary conditions of Dirichlet. They are used thus in agreement with SANS\_GROUP\_NO and SANS\_NOEUD. Excluded directions of friction are indicated by VECT\_Y (in 2D) and VECT\_Y/VECT\_Z (in 3D). The exclusion of the direction of friction makes it possible nevertheless to keep the contacting character of a node.*

*:*

*U4.44.01-II Page*

*: 44/92*

#### *4.21.20 Operand INTEGRATION/MODL\_AXIS*

*The operand "INTEGRATION" makes it possible to select a method of integration numerical for terms of contact and friction. Several methods are implemented; "NODE" for one diagram of integration to the nodes, "GAUSS" for the traditional diagram of Gauss, "SIMPSON" for diagram of Simpson (integration to the nodes and the mediums of the elements) and "DIMENSIONS" for one adaptive diagram in the case of the linear/quadratic contact. The operand `MODL\_AXIS` allows to take into account the axisymmetric character of the problem. These operands are usable only with the "CONTINUOUS" method.*

#### *4.21.21 Operand FORMULATION*

*The operand FORMULATION makes it possible to choose a formulation of the problem in*

*displacement or in*

*speed. This choice relates to the whole of calculation. One uses it in dynamics (it does not have no direction in*

*statics). In dynamics, the advantage of the formulation of speed is to eliminate the oscillations numerical speed and of the acceleration at the time of the impacts.*

*One uses this formulation with a diagram of a nature 1 of speed, available in DYNA\_NON\_LINE, called TETA\_METHODE. This diagram must be selected in the place of the diagram of Newmark or HHT. It*

*require a parameter TETA which takes its values between 0,5 and 1. TETA = 1 gives the maximum of numerical damping usable only with the "CONTINUOUS" method.*

#### **4.21.22 Operand ITER\_CONT\_MAXI/ITER\_FROT\_MAXI/ITER\_GEOM\_MAXI**

*These operands make it possible respectively to fix the maximum number of the iterations of contact, of*

*friction and geometrical. Let us recall that the geometrical loop is a loop which is used for to reactualize pairing, the loop of friction is a fixed loop of point on the threshold of Coulomb whereas the loop of contact is a loop of the type forced active which is used to determine them effective surfaces of contact. These operands are usable only with the method "CONTINUOUS".*

#### **4.21.23 Operand DIRECTION\_APPA**

*This operand makes it possible to specify a direction of research for pairing. The research of points likely to return in contact is not founded any more on the principle of the proximity (the points them*

*closer) but according to the direction DIRECTION\_APPA = (vx, vy, vz) given by the user. In the case of them where pairing by direction is not possible (not main point in direction given), one seeks the main point nearest in a close direction. This operand is usable only with the "CONTINUOUS" method.*

#### **4.21.24 Operand COMPLIANCE**

*This operand makes it possible to activate the model of compliance for the "CONTINUOUS" method. This model*

*takes into account the aspect microscopic of surfaces (asperities) and allows a regularization of model of contact of Signorini. Of dynamics, the contribution of this model consists of the possibility to introduce a density of damping percussion which corresponds to the dissipation of the energy of shock.*

*The law of compliance introduced into Code\_Aster is a polynomial law (see Doc. [R5.03.52]. The three parameters of the law of compliance are ASPERITY, E\_N and E\_V.*

#### ***4.21.25 Operands of resolution***

***These operands make it possible to select a method of calculation following the type of contact (2D/3D and with or without friction) which one wants to treat.***

***METHOD***

=

/

**“FORCED”**

**[DEFECT]**

/

**“LAGRANGIAN”**

/

**“PENALIZATION”**

/

**“CONTINUES”**

/

**“VERIF”**

*This operand makes it possible to use the various methods of resolution.*

**CONSTRAINT**

*: By defect one deals with the problem of the exact unilateral contact without friction with the method of the active constraints of [R5.03.50].*

**LAGRANGIAN**

*: The Lagrangian method makes it possible to treat in an exact way, by multipliers of Lagrange, the problems of contact with or without friction in 2D and 3D.*

**PENALIZATION**

*: The penalized method makes it possible to treat is:*  
*- problems of contact penalized without friction 2D or 3D if  $E_N$  is informed;*  
*- problems of contact with friction in 2D or 3D with a penalization on the terms of friction only if one inform  $E_T$  and a penalization about the terms of contact and of friction if one informs  $E_T$  and  $E_N$ .*

**CONTINUOUS**

*The method continues makes it possible to treat in an exact way, by increased multipliers of Lagrange, the problems of contact with or without friction in 2D and 3D. Coefficients of increase (or regularization) are specified in*

***COEF\_REGU\_CONT and COEF\_REGU\_FROT (these coefficients are strictly positive values.)***

### ***VERIF***

***The method of checking makes it possible to control if two surfaces interpenetrate or not without imposing the conditions of contact.***

***It is thus a method which is worried only aspect geometrical and which is inexpensive in terms of time CPU.***

***One can use it for example to control that the two lips of a crack do not interpenetrate.***

### ***Note:***

***The “CONTINUOUS” method is a modern and promising method. It is however very recent in Code\_Aster. Also advises one with the users rather to choose in a first time one of the other methods and if required to test the method “CONTINUES” in one the second time.***

***For the methods penalized and Lagrangian, one returns for more details to [R5.03.51].***

### ***FRICION***

***=***

***/***

***“WITHOUT”***

***[DEFECT]***

***/***

***“COULOMB”***

*U4.44.01-II Page*

*: 46/92*

*sensitivity of the results compared to this coefficient. To increase then the value of the coefficient until obtaining results stable.*

*E\_N*

*: coefficient of penalization on the interpenetration for the method penalized. It is not used and is not necessary when one another method of resolution that "PENALIZATION" is active.*

*A value about the smallest Young modulus of the solids in contact is initially recommended. In practice the choice on E\_N is broader than that on E\_T and of great values are usable (107 or 108 times the smallest Young modulus). One increase the value of the coefficient until obtaining results stable. Moreover it is possible to control the distances of interpenetration and thus to refine its choice of coefficient, which is not the case of the slip, since one does not know a priori which are the slipping zones and not slipping whereas in case of contact one can check that the distances of interpenetration are not eccentric.*

*COEF\_MATR\_FROT*

*: coefficient, ranging between 0 and 1, of taking into account of the part negative of geometrical rigidity. More this coefficient is large better is convergence when one is close to balance and more the resolution is difficult far from balance. A value of 0.5 thus is initially advised. The defect of 0 ensures systematic convergence for a longer computing time. This coefficient is essential to treat contacts surface with friction in 3D. It is not used the remainder of time.*

#### **COEF\_REGU\_CONT**

*coefficient of increase for the method “CONTINUES” (Lagrangian increased) relating to the regularization of the laws of contact. It can take values of about size of the step time in dynamics (10-5, 10-6...) until much more important (500 for example).*

#### **COEF\_REGU\_FROT**

*coefficient of increase for the method “CONTINUES” (Lagrangian increased) relating to the regularization of the laws of friction.*

#### **SEUIL\_INIT**

*initial threshold value of friction for the method “CONTINUES” (Lagrangian increased). It is by defect null what corresponds to treat during the first iteration of threshold it contact without friction.*

*This option is available only for the “FORCED” method and the method “CONTINUOUS”.*

*It makes it possible to activate the mode of bilateral contact or out of slide, in which two surfaces finding in contact remain “stuck” (i.e. with a null play) some is the evolution of loading. It authorizes great relative slips and the slide mode is not activated before surfaces are indeed in contact (it does not stick a priori two surfaces distant of a play not no one if the loading does not imply it).*

*Operand “ALARME\_JEU” makes it possible to activate an alarm as soon as the algorithm detects that, without the method slide, there would be separation of two surfaces (a virtual play higher than zero). Its value is regulated by defect with 0, which alarms the user as soon as surfaces would have to take off without the activated option.*

#### **4.21.28 Operand SMOOTHING**

*This operand makes it possible to smooth the normals on the surfaces of contact intervening in calculation of the matrix of contact. One will note  $Q$  an unspecified node of surfaces of contact (Master or slave),  $P$  a node of surface slave and  $M$  the main node obtained by projection of the node  $P$ .*

**SMOOTHING**  
 =  
 /“NOT”  
**[DEFECT]**

*For a pairing of the “master-slave” type the calculated normal is the normal entering to the mesh containing  $M$ . For a pairing of the “nodal” type the calculated normal is*

*outgoing normal with the node slave P.*

**SMOOTHING**

=

/“YES”

*Smoothing is done in two stages:*

.

*the first stage of smoothing consists in carrying out an average of the normals with meshes which contain the node Q,*

.

*the second stage consists in calculating an average of the normals at the tops of net container Mr. This average being balanced by the functions of form associated Mr.*

**Note:**

*For a pairing of the NODAL type smoothing does not bring any difference.*

*For a pairing of the type MAIT\_ESCL smoothing has a behavior which varies according to key word NORMAL.*

**NORMAL**

=

/“MAIT”

*The calculation of the matrix of contact is done according to the normal smoothed with the main node.*

**NORMAL**

=

/“MAIT\_ESCL”

*The calculation of the matrix of contact is done according to the average of the normals smoothed with the node*

*slave and with the main node.*

#### **4.21.29 Structure of data VALE\_CONT**

*All the methods of contact with or without friction produce a structure of data of the type VALE\_CONT, which is a cham\_no\_s with the following components, in each node slave:*

.

*CONT: indicator of rubbing contact*

*- 0: no the contact*

*- 1: slipping contact*

*- 2: adherent contact*

.

*PLAY: value of the play*

.

*RN: normal reaction of contact normalizes*

.

*RNX: component according to DX of the normal reaction of contact*

.

*RNY: component according to DY of the normal reaction of contact*

.

*RNZ: component according to DZ of the normal reaction of contact*

.

*GLIX: component according to **T1** of the tangential slip (local reference mark)*

.

*GLIY: component according to **t2** of the tangential slip (local reference mark)*

.

*GLI: normalizes tangential slip*

.

*RTAX: component according to DX of the tangential force of adherence*

.

*RTAY: component according to DY of the tangential force of adherence*

.

*RTAZ: component according to DZ of the tangential force of adherence*

.

*RTGX: component according to DX of the tangential force of slip*

.

*RTGY: component according to DY of the tangential force of slip*

.

*RTGZ: component according to DZ of the tangential force of slip*

.

*X-ray: component according to DX of the force of rubbing contact (RNX+RTAX+RTGX)*

.

*RY: component according to DY of the force of rubbing contact (RNY+RTAY+RTGY)*

.

*RZ: component according to DZ of the force of rubbing contact (RNZ+RTAZ+RTGZ)*

.

*R: force of rubbing contact normalizes*

*It is printed as follows in the form of table:*

```
MATABLE=POST_RELEVE_T (ACTION=_F (INTITULE=' INFOS FROTTMNT',
GROUP_NO=' ESCLAVE',
RESULTAT=U,
INST=10.,

**lgrno**  
,  
**[l\_gr\_noeud]**

**NUME\_LAGR**  
=/"NORMAL",  
**[DEFECT]**  
/  
**"AFTER"**  
,

),

**NUME\_LAGR:**

.

*If "NORMAL", the two multipliers of Lagrange associated with the relation will be such as first will be located before all the terms implied in the relation and the second after, in the assembled matrix.*

.

*If "AFTER", the two multipliers of Lagrange associated with the relation will be located afterwards all terms implied in the relation, the assembled matrix.*

*This choice has the advantage of having an assembled matrix whose obstruction is more weak but has the disadvantage to be able to reveal a singularity in the matrix.*

*Note:*

*In a general way, one imposes:*

•  
*in 2D ( $nb\_ddl * nb\_noeud3$ ) relations*

•  
*in 3D ( $nb\_ddl * nb\_noeud6$ ) relations*

*where*

•  
 *$nb\_ddl$  is the number of degrees of freedom per node,*

•  
 *$nb\_noeud$  is the number of nodes of the list given after `LIAISON_SOLIDE`*

*since a solid is determined by the position of one of its points and a reference mark in it not.*

*Relations are written by taking the vectorial formula translating a movement of rigid body in small rotations:*

*where*  
*is an arbitrary node of the solid.*

#### **4.24 Key word**

**LIAISON\_ELEM**

##### **4.24.1 Drank**

*While calling “left massive” a piece of structure modelled with isoparametric elements 3D, this key word factor makes it possible to model the connection:*

*of a massive part with a part beam [R3.03.03] or a pipe section [R3.08.06],*

*of a hull part with a part beam [R3.06.03] or a pipe section [R3.08.06].*

*The goal of this functionality is not to account for the scales length between the parts to connect but to allow a simplification of modeling by replacing a massive part by a beam part for example.*

*The connection is treated by imposing linear relations between the degrees of freedom of the nodes of junction of the two parts to be connected, without imposing superfluous relations.*

### 4.26.3 Operands

**CHAM\_NO =**

*Name of the cham\_no which is used to define the linear relation. The ddls connected are all those present in chamno. The coefficients to be applied to the ddls are the values of the chamno for these ddls.*

**Example:**

*Let us suppose that one has a bearing chamno on two nodes of name N01 and N02 respectively carriers of ddls “DX”, “DY” and “DZ” for the N01 node and “DX”, “DY”, “DZ”, “DRX”, “DRY” and “DRZ” for the N02 node.*

*Also let us suppose that the chamno has the following values for these ddls:*

2.

**“DX”**

**N01**

1.

**“DY”**

N01

3.

“DZ”

N01

1.

“DX”

N02

4.

“DY”

N02

2.

“DZ”

N02

3.

“DRX”

N02

5.

“DRY”

N02

2.

“DRZ”

N02

*The linear relation that one will impose is:*

$$2.*DX(N01) + 1.*DY(N01) + 3.*DZ(N01) \\ + 1.*DX(N02) + 4.*DY(N02) + 2.*DZ(N02) \\ + 3.*DRX(N02) + 5.*DRY(N02) + 2.*DRZ(N02) =$$

*COEF\_IMPO =*

*It is the value of the real coefficient to the second member of the linear relation.*

*NUME\_LAGR =*

.

*if “NORMAL”, the two multipliers of Lagrange associated with the relation will be such as first will be located before all the terms implied in the relation and the second after, in the assembled matrix,*

.

*if “AFTER”, the two multipliers of Lagrange associated with the relation will be located afterwards all terms implied in the relation, the assembled matrix.*

*This choice has the advantage of having an assembled matrix whose obstruction is more*

*weak but has the disadvantage to be able to reveal a singularity in the matrix.*

#### **4.39 Key word**

**LIAISON\_COQUE**

##### **4.39.1 Drank**

***Key word factor making it possible to represent the connection enters of the hulls by means of relations***

***linear. The traditional approach admits that two plans with a grid in hulls are cut according to a line who belongs to the grid of the structure.***

***That has the disadvantage of twice counting the volume which is the intersection of the two hulls.***

***The idea is thus to stop the grid of a hull perpendicular to a hull given to the level of higher or lower skin of the latter.***

**A2**

**B2**

**A1 B1**

***One represented in features full volume with the hulls and in dotted lines the average plans of these hulls***

***(which results from the grid).***

***The horizontal hull stops in A1 A2 and the projection of A1 A2 on the average level of the vertical hull***

***is B1 B2 (which one represented in full features).***

***The link between the 2 hulls is made by connections of solid body between the nodes in with respect to***

*segments A1 A2 and B1 B2.*

*For example for the nodes A1 and B1, one will write the formula (valid in small rotations):*

*and equality of rotations:*

**4.40** Key word

**RELA\_CINE\_BP**

**4.40.1** Drank

**Key word factor allowing the definition of a loading of the type** *RELA\_CINE\_BP*.

**This type of loading can be defined for a mechanical system including/understanding a structure concrete**

**and its cables of prestressing. Initial profiles of tension in the cables, as well as the coefficients relations kinematics between the ddl of the nodes of the cables and the ddl of the nodes of the structure**

**concrete are beforehand given by operator** *DEFI\_CABLE\_BP* [U4.42.04]. **Concepts** *cabl\_precont* **produced by this operator brings all information necessary to definition of the loading.**

**The multiple occurrences are authorized for the key word factor** *RELA\_CINE\_BP*, **in order to allow in the same call to operator** *AFFE\_CHAR\_MECA* **to define the contributions of each one of groups of cables having been the subject of distinct calls to operator** *DEFI\_CABLE\_BP* [U4.42.04]. **With each group of cables considered, defined by a concept** *cabl\_precont*, **is associated one occurrence of the key word factor** *RELA\_CINE\_BP*.

**The loading thus defined is then used to calculate the state of balance of the unit structure concrete/ cables of prestressing. However, the taking into account of this type of loading is not effective in all the operators of resolution. The loading of the type** *RELA\_CINE\_BP* **is not recognized for the moment that by operator** *STAT\_NON\_LINE* [U4.51.03], **option** *COMP\_INCR* **exclusively.**

**4.40.2 Syntax (AFFE\_CHAR\_MECA only)****RELA\_CINE\_BP****=\_F****(****CABLE\_BP****=****cabl\_pr,****[cabl\_precont]****SIGM\_BPEL****=****/****“YES”,****/****“NOT”,****[DEFECT]****RELA\_CINE****=****/****“YES”,****[DEFECT]****/****“NOT”,****)****4.40.3 Operands****CABLE\_BP = cabl\_pr**

**Concept of the cabl\_precont type produces by operator DEF1\_CABLE\_BP [U4.42.04]. This concept bring on the one hand the chart of the initial constraints in the elements of the cables of same group, and in addition the lists of the relations kinematics between the ddl of the nodes of these**

*cables and ddl of the nodes of the structure concrete.*

**SIGM\_BPEL**

=

/

“YES”,

/

“NOT”,

[DEFECT]

*Indicator of the text type by which one specifies the taking into account of the initial constraints in cables; the default value is “NOT”.*

*In the case “NOT”, only the liaisonnement kinematic one is taken into account. It is useful if one connect STAT\_NON\_LINE whereas one has cables of prestressing. For the first STAT\_NON\_LINE it is necessary to have put “YES”, so that one sets up the tension in cables. On the other hand, for the following STAT\_NON\_LINE, one should not regard as loading that the connections kinematics and thus to define the loading with SIGM\_BPEL = “NOT”, if not the tension is counted twice.*

*Since the restitution the macro one to put in tension the cables, the user would not have any more to need to make a AFFE\_CHAR\_MECA with SIGM\_BPEL = “YES”, that should thus avoid risks of error.*

**GROUP\_MA\_COLL = gma**

*Group meshes defining the zone where the two models are connected. This zone must normally to correspond to meshes of GROUP\_MA\_1 or GROUP\_MA\_2 pertaining to the zone of covering of the two fields. It is however possible that it overflows of this zone of superposition. If the key word is not indicated, the exact zone of superposition is reserve in the algorithm.*

**JOINING =**

*Choice of the model used to define the multipliers of Lagrange of joining (GROUP\_MA\_1 or GROUP\_MA\_2 restricted at the zone of joining). A comparison of the average volume of meshes of the two models allows also the use of END or COARSE.*

**"/POIDS\_1**

**=**

*1,*  
*"/POIDS\_2*

*=*

*2,*  
*"/POIDS\_FIN*  
*= F,*  
*"/POIDS\_GROSSIER = G,*

*Reality lain strictly between 0. and 1. It makes it possible to define the value of the functions of weighting in the zone of superposition. POIDS\_i corresponds to the weight of model I. The data of 1 or 2 makes it possible to describe the couple (1,2) such as: (1,2) = (1,1 - 1) or (1 - 2, 2)*

*CARA\_ELEM =*

*Field of elementary characteristics resulting from AFFE\_CARA\_ELEM (thicknesses for hulls, sections for the beams). To specify obligatorily when one of the two models is composed of hulls.*

#### *4.48.5 Examples and councils of use*

*Operation of junction of models:*

*HARLEQUIN = \_F (*  
*GROUP\_MA\_1*  
*=*

**4.49 Key word**  
**GRAPPE\_FLUIDE**

### **4.49.1 Drank**

**Key word factor allowing the entry of the calculation data of the fluid forces at the time of the studies of fall of bunch.**

*This type of loading is specific to this kind of study. It is associated a preset grid. data entered via a file “include” suitable for the type of assembly of which one study the fall of bunch. Examples of files “include” and grid are available with the cases tests associated with this type of loading. They count, in the form of variables pythons, them data entered under the various single-ended spanner words of the key word factor GRAPPE\_FLUIDE. If one wishes to modify one, or several, values, it is possible to call again upon GRAPPE\_FLUIDE. According to the rule of overload, the last entered value is then that employed for*

*calculation.*

**Caution:**

*Even if, for purely data-processing reasons, the single-ended spanner words appear like optional, it is necessary that all the data entered, that is to say directly by the user, that is to say, as he it is recommended, via the file include.*

**4.49.2 Syntax**

*Applicable to AFFE\_CHAR\_MECA only:*

*GRAPPE\_FLUIDE = \_F (*

### *3 General information*

#### *Possible error messages related to order AFFE\_CHAR\_THER*

*It happens sometimes that a thermal ordering of calculation (THER\_LINEAIRE, THER\_NON\_LINE,...)*

*stop in fatal error during the calculation of the second elementary members due to the loadings defined in the AFFE\_CHAR\_THER\_xx orders.*

*When the code stops during these elementary calculations, important information of the message of error is the name of the option of calculation requested by the code.*

*The name of this option is in general unknown to the user and it is thus difficult for him to include/ understand the message.*

*In the table below, one gives in with respect to the names of the options of calculation, the name of order and key word factor which make it possible to activate this option.*

#### *Elementary option of calculation*

## **4 Operands**

### **4.1** **General information on the operands**

#### **4.1.1 Two forms of operands under a key word factor**

**The operands under a key word factor are of two forms:**

- .**  
**operands specifying the topological entities where the loadings (key words are affected GROUP\_NO and GROUP\_MA, etc...). The arguments of these operands are identical for both operators.**
- .**  
**operands specifying the affected values (TEMP, COEF\_H, etc...). Significance of these operands is the same one for the two operators but the arguments of these operands are all the real type for operator AFFE\_CHAR\_THER and of the function type (created by one of operators DEFI\_FONCTION, DEFI\_NAPPE, DEFI\_CONSTANTE or CALC\_FONC\_INTERP) for operator AFFE\_CHAR\_THER\_F.**

**We will thus not distinguish in this document, except mention express of the opposite, both operators AFFE\_CHAR\_THER and AFFE\_CHAR\_THER\_F.**

#### **4.1.2 Topological entities of assignment of the loadings**

**In a general way, the topological entities on which values must be affected are defined:**

**.**  
**by nodes and in this case:**

**-**  
**maybe by operand GROUP\_NO allowing to introduce a list of group of nodes,**

-  
*maybe by the operand NODE allowing to introduce a list of nodes.*

.  
*by mesh and in this case:*

#### **4.5 Key word**

**FLUX\_NL**

##### **4.5.1 Drank**

Key word factor usable to apply **normal flows** functions of the temperature, with a **face** of voluminal element defined by one or more meshes or of the groups of meshes of the **triangle** type or **quadrangle**. This key word also makes it possible to apply a normal flow to an edge (in *PLANE 2D* or *AXIS*) on meshes of the segment type. One can thus model a condition of radiation of law type of *STEPHAN*. This type of flow is used only by orders *THER\_NON\_LINE* [U4.54.02] and *THER\_NON\_LINE\_MO* [U4.54.03].

The values are provided by a concept of the function type.

##### **4.5.2 Syntax**

### **4.10.3 Operands**

*The list of the nodes Nor ( $I = 1, R$ ) defined by GROUP\_NO or NODE is ordered in a natural way:*

.

*in the order of the list of group of nodes, and for each group of nodes, in the order of definition of the group by GROUP\_NO.*

.

*in the order of the list of nodes for NODE.*

*The argument of DDL must be a list of degrees of freedom  $T_i$  ( $I = 1, R$ ) of  $R$  texts taken among:*

“TEMP”

“TEMP\_SUP”

“TEMP\_INF”

If key word DDL is omitted, by defect the linear relation will carry on the degrees of freedom “TEMP”.

The argument of COEF\_MULT must be a list (I = 1, R) of coefficients (of real type for I

AFFE\_CHAR\_THER and AFFE\_CHAR\_THER\_F).

: 17/28

The argument of COEF\_IMPO is a coefficient for AFFE\_CHAR\_THER, a function of space for AFFE\_CHAR\_THER\_F.

The following kinematic condition is applied:

**Note:**

Components “TEMP\_SUP” and “TEMP\_INF” can intervene only in combinations **only** assigned to nodes which belong to elements of **hull** (modeling “HULL”).

In the case of a linear relation between the degrees of freedom of the same node, one will repeat behind the key word NODE the name of the node as many time as there are degrees of freedom in relation. **Example:** to impose  $T_{sup} = T_{inf}$  on the node N1, one will write:

*LIAISON\_DDL = \_F (NODE  
= (N1, N1),*

*DDL  
=  
("TEMP\_SUP",  
"TEMP\_INF"),*

*COEF\_MULT  
=  
(1., -1.),  
COEF\_IMPO  
=  
0.,*

)

*It is important to note that to an occurrence of the key word factor LIAISON\_DDL one corresponds and only one linear relation.*

*If one wants to impose the same relation between 2 groups of nodes GRN01 and GRN02 (even temperature node with node for example) **one cannot write:***

*LIAISON\_DDL = \_F (GROUP\_NO = (GRN01,  
GRN02),*

*DDL  
=  
("TEMP",  
"TEMP"),*

*COEF\_MULT  
=  
(1., -1.),*

*COEF\_IMPO  
=  
0.,*

)

*This writing has direction only if GRN01 and GRN02 contain each one one node. It will be necessary in the case to above clarify each linear relation, node by node.*

***Key word LIAISON\_GROUP on the other hand makes it possible to condense the writing of the relations linear between 2 groups of nodes in opposite.***

*SUMMIT = “YES”*

*When the meshes of edge are quadratic, the use of SUMMIT: “YES” force the algorithm of pairing to associate the nodes tops other nodes tops. In the case of fine grids, that makes it possible in certain cases to avoid the problems of conflicts of opposite.*

*4.11.4 Use of LIAISON\_GROUP*

*LIAISON\_GROUP generates linear relations only between 2 nodes (one on 1, one out of 2)*

*To generate linear relations on more than 2 nodes, to use key word LIAISON\_DDL.*

*determination of the couples of nodes in opposite:*

*initially, one draws up the two lists of nodes to be put in opposite (IE at to pair), for each occurrence of the key word factor LIAISON\_GROUP:*

*for key words GROUP\_NO\_1 and GROUP\_NO\_2, they are the nodes constituting them groups of nodes,*

*for key words GROUP\_MA\_1 and GROUP\_MA\_2, they are the nodes of the meshes setting up the groups of meshes.*

*The redundancies being eliminated, the two lists of nodes obtained must have the same one length.*

*The determination of the couples of nodes in opposite is done in several stages:*

*for each N1 node of the first list, one seeks the node image  $N2 = F(N1)$  of second list. If F is not injective (a node N2 is the image of two distinct nodes N1 and N1'), the error message according to is transmitted:*

**<F> <AFFE\_CHAR\_THER> <PACOAP> CONFLICT IN OPPOSITE**

**NODES**

*The NODE N2 EAST IT WITH RESPECT TO the NODES N1 AND N1'*

*for each node N2 of the second list, one seeks the node N1 image =  $G(N2)$  of first list. If G is not injective (a N1 node is the image of two distinct nodes N2 and N2'), the error message according to is transmitted:*

**<F> <AFFE\_CHAR\_MECA> <PACOAP> CONFLICT IN OPPOSITE**

**NODES**

*The NODE N1 EAST IT WITH RESPECT TO the NODES N2 AND N2'*

*it is checked that  $G = f1$ , i.e. the couples obtained by the stages has) and b) are them same (one wants to have a bijection  $F$  between the two lists of nodes). If  $F$  is not surjective, the error message according to is transmitted:*

**<F> <AFFE\_CHAR\_MECA> <PACOAP> CONFLICT IN OPPOSITE GENERATE  
SUCCESSIVELY FROM LISTS LIST1 AND LIST2**

***The NODE OF the FIRST N1 LIST IS NOT the IMAGE Of ANY NODE BY***

***CORRESPONDENCE  
OPPOSITE***

***For a node NR given, one calls node image  $F(NR)$  the node of the other list of nodes which carry out the minimum of the distance with NR. to facilitate pairing, in particular in the case particular geometries (where borders 1 and 2 could “almost” result one from the other by the composition of a translation and a rotation), one makes it possible to make a virtual geometrical transformation of the first group of nodes (translation and rotation (cf [Figure 4.11.3-a]) before calculating the distances (key words TRAN, CENTER and ANGL\_NAUT).***

***For each occurrence of the key word factor LIAISON\_GROUP, one builds the list thus of new couples in opposite. When all the occurrences were swept, one removes list the couples in double.***

**X. DESROCHES Key**

:

**U4.44.02-II Page****: 22/28****Note:**

*In the couples of nodes in opposite, the order of the nodes is important. If for first occurrence of LIAISON\_GROUP, a node NR belonged to the first group of nodes and a node M with the second group of nodes, and that for the second occurrence LIAISON\_GROUP, it is the reverse, one will obtain with the exit pairing the couples (NR, M) and (M, NR). They will not be eliminated during detection of the redundancies; on the other hand, stamp obtained will be singular. Thus, one advises to keep same logic at the time of description of the edges in opposite.*

**4.13.4 Use of ECHANGE\_PAROI**

*The user gives two lists of meshes from which the couples from paired nodes will result. These lists are initially sorted by type of mesh: the paired nodes will come from meshes of the identical type. For each mesh of the first list, one determines the mesh nearest in the second list by calculating all the distances from the nodes taken two to two (one traverses all the permutations possible). The distance minimum obtained defines at the same time the mesh in opposite and the couples of nodes paired for the two meshes concerned. As in LIAISON\_GROUP [§4.11], it is possible to carry out a virtual geometrical transformation (rotation and/or translation) before to calculate the distances.*

### ***4.15 Key word***

***LIAISON\_CHAMNO***

#### ***4.15.1 Drank***

***Key word factor usable to define a linear relation between all the temperatures present in a concept CHAM\_NO.***

## 4.15.2 Syntax

**LIAISON\_CHAMNO = \_F (**  
**CHAM\_NO = *chamno*,**

**[*cham\_no*]**

**COEF\_IMPO =,**

**[R]**

**NUME\_LAGR**

**=**

**/**

**“NORMAL”,**

**[DEFECT]**

**/**

**“AFTER”**

**,**

**)**

### 4.15.3 Operands

**CHAM\_NO =**

*Name of the chamno which is used to define the linear relation. The temperatures connected are all those present in the chamno. The coefficients to be applied to the temperatures are the values of these temperatures in the chamno.*

**Example:**

*Let us suppose that one has a bearing chamno on 3 nodes of name N01, N02 and N03.*

*Let us suppose that the values of the temperatures in these 3 nodes in the chamno are respectively 2. , 5.4 and 9.1. The linear relation that one will impose is  $2.*Temp(N01) + 5.4*Temp(N02) + 9.1*Temp(N03) =$*

**COEF\_IMPO =**

*It is the value of the real coefficient to the second member of the linear relation.*

**NUME\_LAGR =**

*If "NORMAL", the 2 multipliers of Lagrange associated with the relation will be such as the first will be located before all the terms implied in the relation and the second after, in the assembled matrix.*

*If "AFTER", the 2 multipliers of Lagrange associated with the relation will be located after all the terms implied in the relation, the assembled matrix.*

*This choice has the advantage of having an assembled matrix whose obstruction is weaker but has the disadvantage to be able to reveal a singularity in the matrix.*

**: 28/28**

#### **4.16 Key word**

**CONVECTION**

##### **4.16.1 Drank**

*Key word usable to take into account the term of transport of heat by convection of which the expression is*

*, appearing in the expression of the particulate derivative*

.

*In the case of a liquid medium, V indicates the speed imposed of the fluid particle on the current point.*

*In the case of a mobile solid medium, V indicates the speed of the solid. In all the cases, one supposes that the field speed is known a priori. The case of a mobile solid is rather frequent in practice. It relate to in particular the applications of welding or surface treatment which bring into play one heat source moving in a given direction and at a speed.*

*The thermal problem is then studied in a reference frame related to the source (cf*

**THER\_NON\_LINE\_MO**

**[U4.54.03]).**

##### **4.16.2 Syntax**

**CONVECTION = \_F (**  
**SPEED**

**=**

**v**

**[cham\_no\_depl\_R])**

##### **4.16.3 Operand**

**For AFFE\_CHAR\_THER and AFFE\_CHAR\_THER\_F,**

***SPEED =***

***Name of the field speed at the moment when calculation is carried out.***

***This field is a concept cham\_no of the cham\_no\_depl\_R type. It must have been defined on all it model for which one carries out calculation.***

### *3 General information*

*These two orders create concepts of the type CHAR\_CINE\_\* (\_MECA/\_THER).*

*Order AFFE\_CHAR\_CINE can also create concepts of the type CHAR\_CINE\_ACOU.*

*These types are different from the type charges created by orders AFFE\_CHAR\_MECA [U4.44.01], AFFE\_CHAR\_THER [U4.44.02] or AFFE\_CHAR\_ACOU [U4.44.04].*

*The objects created are thus not interchangeable.*

*The advantage of the loads “kinematics” is that they do not increase the number of unknown factors of systems to be solved, contrary to the method of dualisation by multipliers of LAGRANGE, used in the orders producing a concept of the type charges.*

*On the other hand, the use of these loads comprises the following limitations:*

- *one can use them only in the case of relation of the type “ddl imposed” (and not for linear relations),*

- *these loads are not yet allowed in all the total orders. Today the possible orders are:*

- *MECA\_STATIQUE,*

- *THER\_LINEAIRE, THER\_NON\_LINE or THER\_NON\_LINE\_MO.*

- *for a calculation not using the total orders: assembly of a matrix, then resolution, the sequence of orders to be used is more complicated than with loads “ordinary” as one can see it in example 2 [§ 5.2].*

## 4 Operands

### 4.1

#### *General information on the operands*

*The operands under the key words factors MECA\_IMPO, THER\_IMPO and ACOU\_IMPO are two forms:*

- *operands specifying the geometrical entities on which are affected them loadings (key words GROUP\_MA, GROUP\_NO, NODE...). Arguments of these operands are identical for the two operators.*

- *operands specifying the affected values (DX, DY, DZ, etc...). Significance of these operands is the same one for the two operators. The arguments of these operands are all real type for operator AFFE\_CHAR\_CINE and of the function type (or formulates) for operator AFFE\_CHAR\_CINE\_F.*

*This is true near with an exception: the key word factor ACOU\_IMPO (which does not exist in order AFFE\_CHAR\_CINE\_F) is always of complex type.*

*We will thus not distinguish in this document, except mention express of the opposite, both operators AFFE\_CHAR\_CINE and AFFE\_CHAR\_CINE\_F.*

*In a general way, the entities on which values must be affected are defined by nodes:*

- *maybe by the operand ALL = "YES" which makes it possible to indicate all the nodes of the grid,*

- *maybe by operand GROUP\_NO allowing to indicate a list of groups of nodes,*

- *maybe by the operand NODE allowing to indicate a list of nodes.*

- *maybe by the operands GROUP\_MA and MESH allowing to indicate all the nodes carried by the meshes indicated by the lists of MESH and GROUP\_MA.*

### 4.2

#### *Behavior in the event of overload:*

##### *4.2.1 Overload within one only order AFFE\_CHAR\_CINE*

*When one uses within the same order, several occurrences of MECA\_IMPO (or THER\_IMPO,...) and that certain nodes are affected several times, it is the last occurrence which precede. For example:*

*chcine= AFFE\_CHAR\_CINE (MECA\_IMPO= (  
\_F (TOUT=' OUI', DX= 1. ,...)  
\_F (NOEUD=' N3', DX= 3. ,...)*

*In this case, displacement imposed DX for the N3 node is worth: 3.*

#### **4.2.2 Overload between several orders AFFE\_CHAR\_CINE**

*If several different orders are used, the behavior is different. For example:*

*chcin1= AFFE\_CHAR\_CINE (MECA\_IMPO= \_F (TOUT=' OUI', DX= 1. ,...)  
chcin1= AFFE\_CHAR\_CINE (MECA\_IMPO= \_F (NOEUD=' N3', DX= 3. ,...)*

*In this case, displacement imposed DX for the N3 node is worth: 4! (1+3).*

#### **4.2.3 Overload**

*enter*

*AFFE\_CHAR\_CINE and AFFE\_CHAR\_MECA*

*In the same way, if one “mixes” orders AFFE\_CHAR\_MECA and AFFE\_CHAR\_CINE:*

*chcin1= AFFE\_CHAR\_CINE (MECA\_IMPO= \_F (TOUT=' OUI', DX= 1. ,...)  
chdua1= AFFE\_CHAR\_MECA (DDL\_IMPO= \_F (NOEUD=' N3', DX= 3. ,...)*

*In this case, displacement imposed DX for the N3 node is worth: 4! (1+3).*

### **3 Operands**

#### **3.1 Operand**

**MODEL**

**MODEL = Mo**

*Name of the model whose grid supports the elements of acoustic calculation.*

#### **3.2 Operand**

**VERI\_DDL**

**VERI\_DDL =/“YES”**

/

**“NOT”**

*Allows to check that the DDLs goods are well presented, i.e. here the DDL “CLOSE” (cf [§3.4]).*

#### **3.3 Words**

keys

**PRES\_IMPO/VITE\_FACE/IMPE\_FACE**

##### **3.3.1 Drank**

*Key words factors giving it natural of the conditions imposed on the specified elements (nodes, or*

*groups of nodes, meshes or groups of meshes).*

***I  
PRES\_IMPO***

*Allows to impose the DDL of pressure.*

***I VITE\_FACE***

*Allows to specify the vibratory field speed imposed in loading on elements of border.*

***I IMPE\_FACE***

*Allows to specify the chart of impedance imposed in boundary condition on elements of border.*

### ***3.3.2 Operands***

***ALL/NODE/GROUP\_NO/MESH/GROUP\_MA***

*Declaration of the topological entities to which the loadings are applied, conditions with limits.*

***Instruction manual***

***U4.4- booklet: Modeling***

***HT-66/04/004/A***

---

***Code\_Aster ®***

***Version***

***Author (S):***

***NR. GREFFET, F. STIFKENS Key***

***:***

***U4.44.04-G Page***

***: 4/4***

### 3.3.3 Operands

#### ***CLOSE/VNOR/IMPE***

***CLOSE = pre***

***Value (complex) of the acoustic DDL of pressure (only DDL in acoustic modeling) imposed on the nodes or groups of specified nodes.***

***VNOR = vn***

***Value (complex) of the component on the normal external with the meshes or groups of meshes specified, the vibratory speed of the fluid.***

***IMPE = Z***

***Value (complex) of the acoustic impedance imposed on the meshes or groups of meshes specified.***

### 3.4 Word

***key***

***LIAISON\_UNIF***

#### 3.4.1 Drank

***Key word factor allowing to impose the same value (unknown) on degrees of freedom of one together of nodes.***

#### 3.4.2 Operands

***NET/GROUP\_MA/NODE/GROUP\_NO***

***These operands make it possible to define a list of N nodes Nor from which one eliminated the redundancies (for MESH and GROUP\_MA, they are connectivities of the meshes).***

#### 3.4.3 DDL

***This operand can be worth in acoustic modeling, only the text “CLOSE”, defining only degree of freedom allowed, acoustic pressure p.***

***The resulting imposed conditions are:***

***$(p_{N1}) = (p_N)$  for  $I \{2, \dots, \} N$***

**I**

#### **4 Example**

```
cha = AFFE_CHAR_ACOU (MODEL = Mo,  
VITE_FACE  
=  
_F (  
NET  
=  
m4  
,  
VNOR = ("IH", 0.0135, 0. )),  
IMPE_FACE  
=  
_F (  
NET  
=  
m5  
,  
IMPE = ("IH", 442. , 0. )))
```

**Note:**

**The complex values are provided under one of two forms IH (left real, left imaginary) or MP (module, phase in degrees).**

*3 Operands*

*3.1*

*General information on the operands*

*3.1.1 Two categories of operands*

*The operands under a key word factor are of two forms:*

*.*

*operands specifying the geometrical entities on which are affected them  
loadings (key words GROUP\_NO, GROUP\_MA, etc...),*

*.*

*operands specifying the affected values (DX, DY, etc...). Arguments of these operands all are of the complex type.*

*This is true near with an exception: the argument of COEF\_MULT for the key word factor LIAISON\_DDL is obligatorily of real type.*

### *3.1.2 Designation of the topological entities of assignment of the loadings*

*In a general way, the entities on which values must be affected are defined:*

*.  
on all the grid by the operand ALL = "YES"*

*.  
by node and in this case:*

*- is by operand GROUP\_NO allowing to introduce a list of groups of nodes,*

*-  
maybe by the operand NODE allowing to introduce a list of nodes.*

*.  
by mesh and in this case:*

*- is  
by  
GROUP\_MA allowing to introduce a list of groups of meshes,*

*- is  
by  
NET allowing to introduce a list of meshes.*

### *3.1.3 Regulate of overload*

*To define the field of assignment most simply possible, the rule of overload is used defined in the document "Course of a study with Aster ":  
it is the last assignment which precedes.*

## *3.2 Operand MODEL*

*MODEL  
= Mo*

*Concept produced by operator AFFE\_MODELE [U4.41.01] where the types of elements are defined*

*stop affected on the grid.*

### **3.4.3 Operands: choice of the degree of freedom**

**/DDL\_IMPO**

**All the specified values are defined in the TOTAL reference mark of definition of the grid.**

**$DX = ux$**

**Value of the component of displacement in imposed translation**

**$DY = uy$**

**on the specified nodes**

**$DZ = uz$**

**Only if the specified nodes belong to discrete elements of translation - rotation and of beam:**

**$DRX = \theta_x$**

**Value of the component of displacement in rotation imposed on**

**$DRY = \theta_y$**

**specified nodes**

**$DRZ = \theta_z$**

**Only if the specified nodes belong to elements of beam "POU\_D\_TG":**

**$GRX = G$**

**Value of the warping of the beam**

**Only if the specified nodes belong to elements fluid or fluid structure:**

**$PRES = p$**

**Acoustic pressure in the fluid (modeling "3D\_FLUIDE")**

**$PHI = \phi$**

**Potential of displacements of the fluid (modelings "3D\_FLUIDE" and "FLUI\_STRU")**

**Only if the specified nodes belong to elements of free face:**

**$DZ = uz$**

**Imposed displacement of the free face (modeling**

**“2D\_FLUI\_PESA”**

***PHI = phi***

***Potential of displacements of the fluid (modeling***

**“2D\_FLUI\_PESA”**

### **3.4.4 Checks and recommendations**

***It is checked that the specified ddl exists in this node for the elements affected in the MODEL to meshes which contain the node.***

***However, if the same boundary condition is specified twice by two calls to AFFE\_CHAR\_MECA\_C (for example, with two values of imposed displacement), that led to one singular matrix.***

***If it is specified twice (or more) in only one call to AFFE\_CHAR\_MECA\_C, the rule of overload applies and a message of alarm (indicating the overload) is transmitted.***

### **3.5 Word**

***key***

***LIAISON\_DDL***

#### **3.5.1 Drank**

***Key word factor usable to define a linear relation between degrees of freedom of two or***

*several nodes.*

### 3.5.2 Syntax

**LIAISON\_DDL = \_F (**

**/**

**NODE**

**= lno,**

**[l\_noeud]**

**/**

**GROUP\_NO**

**= lgrno,**

**[l\_gr\_noeud]**

**DDL=**

**/ "DX",**

**/ "DY",**

**/ "DZ",**

/ “DRX”,

/ “DRY”,

/ “DRZ”,

/ ...

*COEF\_MULT*

=

*alpha<sub>i</sub>, [l\_R]*

*COEF\_IMPO*

=

*beta, [C]*

)

### **3.5.3 Operands**

***GROUP\_NO or NODE: list nodes NR (I***

***R***

***I***

***= 1,) ordered in a natural way:***

.

***in the order of the list of groups of nodes, and for each group of nodes,  
in the order of definition of the group by GROUP\_NO,***

.

***in the order of the list of nodes for NODE.***

***DDL: list ddl U (I***

***R***

***I***

***= 1,) of R texts taken among:***

***“DX”,***

***“DY”,***

***“DZ”,***

***“DRX”,***

**“DRY”,**  
**“DRZ”**

**COEF\_MULT: list alpha (I**

**R**  
**I**  
**= 1,) of coefficients of the real type.**

**COEF\_IMPO: coefficient beta of the complex type.**

**R**  
**The following kinematic condition will be applied: alpha U = beta**

**I**  
**I**

**I = 1**

### **3.5.4 Precautions of use**

#### **3.5.4.1 Components in rotation**

**The components of displacement in rotation DRX, DRY, DRZ can intervene only in combinations only assigned to nodes which belong to elements discrete or of beam (see DDL\_IMPO).**

#### **Linear 3.5.4.2 Relation between the ddl of the same node**

**In this particular case, one will as many repeat behind the key word NODE the name of the node time as it**

**y has ddl in the relation. Example: to impose  $U = U$**

**X**  
**y on the node N1, one will write:**

**LIAISON\_DDL = \_F (NODE**

**= (“N1”, “N1”),**

**DDL**

**=**

**(“DX”**

**“DY”),**

**COEF\_MULT**

**=**

**(1., -1.),**

**COEF\_IMPO**

**=**

**(IH**

0.,  
0.),

)  
**Instruction manual**  
**U4.4- booklet: Modeling**  
**HT-66/05/004/A**

---

**Code\_Aster** ®  
**Version**  
**7.4**

**Titrate:**  
**Operator AFFE\_CHAR\_MECA\_C**

**Date:**  
**31/01/05**  
**Author (S):**  
**X. DESROCHES Key**  
**:**  
**U4.44.05-E Page**  
**: 7/8**

### **Linear 3.5.4.3 Relation between groups of nodes**

**It is important to note that to an occurrence of the key word factor *LIAISON\_DDL* one corresponds and only one linear relation.**

**If one wants to impose the same relation between 2 groups of nodes *GRN01* and *GRN02* (even displacement *Ux* node with node for example) one cannot write:**

***LIAISON\_DDL* = *\_F* (*GROUP\_NO* = (“*GRN01*”, “*GRN02*”),  
*DDL*  
=  
 (“*DX*”,  
 “*DX*”),  
*COEF\_MULT***

=  
 (1.,  
 -1.),  
**COEF\_IMPO**

=  
 (**IH**  
 0.,  
 0.)  
 , )

*This writing has direction only if GRNO1 and GRNO2 contain each one one node. It will be necessary in the case to above clarify each linear relation, node by node.*

### **3.6 Word**

*key*

**FORCE\_POUTRE**

#### **3.6.1 Drank**

*Key word factor usable to apply linear forces, to elements of the beam type (POU\_D\_T\_, POU\_D\_E,...) defined on all the grid or one or more meshes or of the groups meshes. The forces are definite component by component, either in the TOTAL reference mark, or in the local reference mark of the element defined by operator AFFE\_CARA\_ELEM [U4.42.01].*

#### **3.6.2 Syntax**

### **3 Operands**

#### **3.1 Operand**

##### **OPERATION**

**OPERATION = defines the type of operation to be carried out with this operator:**

**“AFFE”**

**: creation of a structure of data result starting from fields,**

**“ECLA\_PG”:** creation of a structure of data on a grid burst for visualization,

**“PERM\_CHAM”:** reorganization of the fuel assemblies,

**“PROL\_RTZ”:** prolongation of a field 1D on an axisymmetric structure.

**This key word makes it possible to guide the user during the construction of the command file using the tool *eficas*.**

**The structure of data result is *réentrante* and for OPERATION = AFFE the fields existing can be replaced according to the values of the variable of access INST by using them values indicated behind the key words PRECISION and CRITERION. When there is replacement of an existing field, the code transmits a message of alarm, if not the fields are stored at the end structure of data.**

#### **3.2 Operand**

##### **TYPE\_RESU**

**TYPE\_RESU:** Type of the structure of data result created.

#### **3.3 Operand**

##### **NOM\_CHAM**

**NOM\_CHAM:** Reference symbol of the affected size.

#### **3.4 Word**

**key**

## **CHAM\_GD**

### **3.4.1 Operand**

#### **CHAM\_NO**

**CHAM\_NO = chno**

*chno is a cham\_no of function created by order AFFE\_CHAM\_NO [U4.44.11] and in this case one evaluates for each node the function and each moment defined behind LIST\_INST or INST one creates a cham\_no realities, or chno is a cham\_no realities created by the order AFFE\_CHAM\_NO or RECU\_CHAMP and it field is as many duplicated once as the list of moments defined behind LIST\_INST or INST it require.*

### **3.4.2 Operands**

**MODEL, CHAM\_MATER, CARA\_ELEM**

*These operands optional are used to allow the filling of the structures of data result. This filling is essential if order CREA\_RESU is called by MACRO\_ELAS\_MULT to then use the orders of postprocessing which will seek this information in the SD.*

**MODEL = Mo,**

*Name of the model whose elements are the subject of calculation.*

**CHAM\_MATER = chmat,**

*Name of the material field.*

**CARA\_ELEM = carac,**

*Name of the characteristics of the structural elements (beam, hull, discrete,...) if they are used in the model.*

**Instruction manual**

**U4.4- booklet: Modeling**

**HT-62/06/004/A**

---

**Code\_Aster ®**

**Version**

**8.2**

**Titrate:**

**Author (S):**

**J.P. LEFEBVRE, L. VIVAN Key**

**:**

**U4.44.12-G1 Page:**

**6/10**

### **3.4.3 Operands**

**LIST\_INST/NUME\_INIT/NUME\_FIN**

**/**

**LIST\_INST = litps**

**List realities produced by DEFI\_LIST\_REEL [U4.34.01].**

**NUME\_INIT = nuini**

**NUME\_FIN =**

**nufin**

**The moments of calculation are those defined in the concept litps taken between the nuini and it nufin number of moment. In the absence of key word NUME\_FIN, it is the size of the list of realities who is taken into account.**

### **3.4.4 Operands**

**INST**

**/**

**INST = linst**

**List realities: list moments for which the cham\_no of function will be evaluated, or well the cham\_no of realities will be affected.**

**Note:**

**The sequence number created in the concept result is is recovered starting from the value variable of access INST when it is present, is affected with the maximum value**

*immediately above.*

### **3.4.5 Operands**

#### **PRECISION/CRITERION**

*These operands make it possible to refine the access by real variables of access of time.*

#### **I PRECISION**

=

/

*prec*

[*R*]

/

**1.0D-3**

*or*

**1.0D-6**

[**DEFECT**]

*This key word makes it possible to indicate that one seeks all the fields of which the moment (respectively frequency) is in the interval “ $inst \pm prec$ ” (cf **CRITERION**).*

*By defect  $prec = 1.0D-3$ .*

#### **I CRITERION**

=

/

**“RELATIVE”**

[**DEFECT**]

/

**“ABSOLUTE”**

**“RELATIVE”**: *the interval of research is: [ $inst (1 - prec)$ ,  $inst (1 + prec)$ ]*

**“ABSOLUTE”**: *the interval of research is: [ $inst - prec$ ,  $inst + prec$ ].*

### **3.4.6 Operands**

#### **NUME\_MODE/TYPE\_MODE**

**NUME\_MODE** = *num*

*Entirety indicating the number of the harmonic of Fourier of the field stored in a concept of the type **fourier\_elas**.*

***TYPE\_MODE =/"SYME"***

***/***

***"ANTI"***

***/***

***"ALL"***

***The type of the mode of stored Fourier defines.***

***"SYME": symmetrical harmonic***

***"ANTI": antisymmetric harmonic***

***"ALL": symmetrical and antisymmetric harmonic***

### ***3.4.7 Operand***

***NOM\_CAS***

***NOM\_CAS = nomc***

***Character string defining the variable of access of the field stored in a concept of the type mult\_elas.***

*See [U4.44.14].*

**5**  
**Operands associated with the fuel assemblies**

### **5.1 Operands**

**RESU\_INIT**

**RESU\_INIT =**

*Name of the SD evol\_noli containing the fields to be transferred on the new grid.*

### **5.2 Operands INST\_INIT/PRECISION/CRITERE**

**INST\_INIT =**

*Moment characterizing in the SD evol\_noli indicated under RESU\_INIT, the fields to be transferred on the other grid. By defect, the last filed moment is selected*

**PRECISION =**

*Precision used to seek the moment specified by INST\_INIT in the SD evol\_noli associated RESU\_INIT.*

**CRITERION**

**=**

**/**

**“RELATIVE”**

**[DEFECT]**

**/**

**“ABSOLUTE”**

*Criterion used to seek the moment specified by INST\_INIT in the associated SD evol\_noli with RESU\_INIT.*

### **5.3 Operands**

**MAILLAGE\_INIT**

**MAILLAGE\_INIT =**

*Name of the grid on which the SD evol\_noli indicated under RESU\_INIT was defined.*

#### **5.4 Operands**

**RESU\_FINAL**

**RESU\_FINAL = resu**

*Name of the SD evol\_noli definite on the new grid on which they will be transferred fields. It is also in this case the name of the outgoing concept of order CREA\_RESU. structure of data resu must exist (it will have been created for example by the order STAT\_NON\_LINE) and should contain one sequence number.*

#### **5.5 Operands**

**MAILLAGE\_FINAL**

**MAILLAGE\_FINAL =**

*Name of the structure of data grid created on the new grid on which will be to transfer the fields.*

*Instruction manual*

#### **5.6.1 Operands**

## ***GROUP\_MA\_FINAL***

***GROUP\_MA\_FINAL = gma\_2***

***Name of the group of meshes of the MAILLAGE\_FINAL, place where the fields are transferred in RESU\_FINAL.***

### ***5.6.2 Operands***

#### ***GROUP\_MA\_INIT***

***GROUP\_MA\_INIT = gma\_1***

***Name of the grid on which the SD evol\_noli indicated under RESU\_INIT was defined.***

### ***5.6.3 Operand***

#### ***TRAN***

***TRAN = (tx, ty, tz)***

***Vector translation allowing to obtain GROUP\_MA\_FINAL geometrically from GROUP\_MA\_INIT.***

### ***5.6.4 Operand***

#### ***PRECISION***

***PRECISION = prec***

***Absolute precision making it possible to check the good adequacy enters the initial meshes and them final meshes, by defect the value is fixed at 10-3.***

## ***6 Operands associated with projection on a grid axisymmetric***

### ***6.1 Word***

#### ***key***

#### ***PROL\_RTZ***

***Construction of a thermal transient on an axisymmetric grid (3D) starting from the data of one thermal transient calculated on a grid 1D. The transient 1D is given in the form of one structure of data COUNTS resulting from order POST\_RELEVE\_T having the parameters following:***

***.  
the definition of the moments (“INST”),***

•  
*co-ordinates of the nodes of the grid 1D (“COOR\_X”)*

•  
*the value of the temperatures to the nodes (“TEMP”).*

*The co-ordinates of the table must necessarily have for origin the node of co-ordinate 0.*

*The values of the temperatures can possibly be prolonged regularly or interpolated linearly according to co-ordinate “COOR\_X”.*

### **6.1.1 Operands**

**MAILLAGE\_FINAL**

**MAILLAGE\_FINAL =**

*Name of the grid on which one carries out projection, the operator checks that the grid is three-dimensional.*

### **6.1.2 Operands**

**COUNT**

**COUNT =**

*Name of a structure of data COUNTS resulting from order POST\_RELEVE\_T containing it thermal transient 1D. The parameters of this table are obligatorily: “INST”, “COOR\_X” and “TEMP”.*

*Instruction manual*

*U4.4- booklet: Modeling*

**U4.44.12-G1 Page:**

**9/10**

### **6.1.3 Operands**

#### ***INST/LIST\_INST/PRECISION/CRITERION***

/

***INST = litps***

***List actual values.***

/

***LIST\_INST = litps***

***List realities produced by DEF1\_LIST\_REEL [U4.34.01].***

***PRECISION =***

***Precision used to seek the moment specified in the TABLE post\_ID.***

***CRITERION =***

***Criterion used to seek the moment specified in the TABLE post\_ID.***

### **6.1.4 Operands**

#### ***PROL\_DROITE and PROL\_GAUCHE***

***The projection of the transient is carried out according to co-ordinate COOR\_X considered as co-ordinate R in the cylindrical reference mark of the grid 3D. One can define using these two operands the way of prolonging the field beyond the terminals defined by the beach of variation of parameter "COOR\_X" in the table.***

***PROL\_DROITE and PROL\_GAUCHE =***

***Define the type of prolongation on the right (on the left) of the field of definition of the variable:***

.

***"CONSTANT" for a prolongation with the last (or first) value of function,***

.

***"LINEAR" for a prolongation along the first definite segment (PROL\_GAUCHE) or of the last definite segment (PROL\_DROITE),***

.

***"EXCLUDED"***

*if the extrapolation of the values apart from the field of definition of parameter is prohibited (in this case if a calculation requires a value function out of the field of definition, the code will stop in fatal error).*

### **6.1.5 Operand**

**REPERE/ORIGINE/AXE\_Z**

**LOCATE = "CYLINDRICAL"**

*The reference mark of work to project the transient is supposed to be cylindrical, the transient 1D being regarded as the radial variation of the field of temperature. The two operands following allow to carry out a change of reference mark.*

**ORIGIN = (ori1, ori2, ori3)**

*Corresponds to the position of the origin of the grid 1D compared to the origin of the grid 3D.*

**AXE\_Z = (axe1, axe2, axe3)**

*Definition of the axis of the cylindrical reference mark.*

### *3 Operands*

#### *3.1 General*

*The order transforms SD\_resultat (and its subjacent grid) into a news SD\_resultat and a new grid.*

*The meshes of the initial grid are burst in smaller meshes: 1 mesh by point of Gauss. These new meshes all are disjoined (i.e they are not connected between them).*

*The value of a field on a point of Gauss is then assigned to all the nodes of the small mesh which he is associated.*

*SD\_resultat produced is thus a little particular because the fields (which keep their original name) are actually fields with the nodes!*

*Such a structure of data is intended above all for a visualization (after IMPR\_RESU). But one can also consider other postprocessings: POST\_RELEVE, PROJ\_CHAMP,...*

#### *3.2 Operands*

*RESU\_INIT*

*RESU\_INIT: resu\_1*

*Name of the result post-to treat*

### **3.3 Operands**

#### **MODELE\_INIT**

**MODELE\_INIT: Mo**

*Name of the model associated with the resu\_1 result.*

### **3.4 Operand**

#### **NOM\_CHAMP**

**NOM\_CHAM:**

*Reference symbol of (or of) the fields post-to be treated.*

#### **Note:**

*One treats only the fields by elements with the points of integration (standard ELGA)*

### **3.5 Operand**

#### **SHRINK**

**SHRINK = HS**

*Homothetic factor of reduction allowing to ensure nonthe interpenetration of the meshes.*

**SHRINK: 0,9**

**SHRINK: 0,5**

**Not Gauss**

***U4.4- booklet: Modeling***

***U4.44.22 document***

***Operator MODI\_OBSTACLE***

***1 Goal***

***To calculate the obstacles in the systems guidance-tube, after wear.***

*The concept result of MODI\_OBSTACLE is of obstacle type. It is expressed in co-ordinates polar, it is of the same type as that of DEFI\_OBSTACLE with “DISCRETE” keyword and sound use is the same one. This form called figure of play is usable in the operator DYNA\_TRAN\_MODAL under the key word OBSTACLE.*

*This calculation can intervene following a calculation of dynamics with DYNA\_TRAN\_MODAL. One calculates initially the volumes used with operator POST\_USURE. TABL\_USURE resulting from POST\_USURE contains the volumes used during dynamic calculation. MODI\_OBSTACLE uses TABL\_USURE to calculate the new figure of play after wear.*

*The use of the empirically given laws specific starting from the experience feedback on control rods currently limits the use of this option to the specific case of it component.*

*Product a concept result of the obstacle type.*

“GUID\_F\_GCONT\_1300”  
“GUID\_C\_GCOMB\_1300”  
“GUID\_F\_GCOMB\_1300”

### **3.2 Operand**

#### **PENCIL/R\_MOBILE**

*Useless operand when one uses a guide “GUID\_\*\_\*\_\*”, the definition of the pencil (900 or 1300MW) then is already informed by defect.*

*The keywords “PENCIL” or “R\_MOBILE” are thus optional (of type PRESENT-ABSENT). They allow to define the mobile structure of which it is necessary to hold account in the definition of the figure of play.*

*For pencil, the type results from DEFI\_OBSTACLE.*

*It is of “DISCRETE” type or “CRAYON\_900” or “CRAYON\_1300” if the option is not used  
TABL\_USURE.*

*It is obligatorily of type “CRAYON\_900” or “CRAYON\_1300” if option TABL\_USURE is used because the removal of the preset forms of wear is valid only starting from the new antagonists.*

*For rcray, indicate the ray of the pencil in meter.*

### **3.3 Operand OBSTACLE**

*The optional keyword OBSTACLE makes it possible to introduce the initial figure of play figure0 from which one calculates the obstacle figure1 result.*

*If figure1 = MODI\_OBSTACLE (reuse = figure1, the obstacle figure0 is modified at exit of MODI\_OBSTACLE.*

### **3.4 Operand BORING**

*The optional keyword BORING applies to the tube. It makes it possible to give the ratio thickness used on initial thickness which sets off an alarm. The release of alarm corresponds to one boring of the tube.*

### **3.5 Operands V\_USUR\_OBST and V\_USUR\_TUBE**

*Keywords V\_USUR\_OBST and V\_USUR\_TUBE make it possible the user to give volumes used to apply respectively to the obstacle and the tube. vusob and vustu are lists of volumes used by angular sector. They have the same structure as the lists of worn volumes resulting from POST\_USURE.*

*These key words are used only to carry out calculations of test using MODI\_OBSTACLE. At the time use of MODI\_OBSTACLE following a dynamic calculation, one more often uses TABL\_USURE.*

### **3.6 Operands TABL\_USURE and INST**

*tabuse is a table of wear defined by POST\_USURE. It contains the volumes used on the guide and on the pencil by angular sectors and for various dates.*

*MODI\_OBSTACLE reads the volumes used at the moment inst and applies these volumes to the guide and to pencil according to precise profiles'. These profiles result from the experience feedback.*

*These rules are valid only starting from new obstacles. I.e. the guide and the pencil used must be defined by “GUID\_\*\_\*\_\*” (and “CRAYON\_\*”) in DEFI\_OBSTACLE.*

*In the case of the use of option INST of TABL\_USURE several times of continuation, it is necessary to take care of  
to control well the dates and cumulated moments preserved in table TABL\_USURE.*

## ***1 Goal***

***To define a spectrum of turbulent excitation. Various types of spectra are available:***

- for the “beams of tubes under transverse flow”, spectra of the type “length of correlation”,***
- for established uniform flows, parallel with plane or cylindrical structures circulars, spectra of turbulence of boundary layer,***
- spectrum of excitation defined by its decomposition on a family of functions of form in providing a matrix interspectrale and a list of associated functions of form. concepts *tabl\_intsp* and function must then be generated upstream,***
- preset spectrum of turbulence, identified on model GRAPPE1 or GRAPPE2,***
- spectrum of excitation associated with one or more forces and specific moments while providing a matrix interspectrale of excitations (concept *tabl\_intsp* having to be generated upstream), the list of the nodes of application of these excitations, the nature of the excitation applied in each one of these nodes (force or moment) and directions of application of the excitations thus defined.***

***Product a concept of the spectrum type.***

### **3 Operands**

#### **3.1 Key words**

**SPEC\_LONG\_COR\_n**

*The definition of a spectrum of excitation of the type “length of correlation” can be done only by one only occurrence of one of the key words SPEC\_LONG\_COR\_n factors, corresponding to a zone of the tube*

*defined beforehand by the function indicated in operand PROF\_VITE\_FLUI of the order DEFI\_FLUI\_STRU [U4.25.01]. Profile speed associated with this zone, pointed out here under the operand*

*PROF\_VITE\_FLUI, must be identical to that indicated in DEFI\_FLUI\_STRU [U4.25.01]. The use spectra of excitation of the type “length of correlation” is limited to the configuration “beam of tubes under transverse flow” (key word factor FAISCEAU\_TRANS of the operator DEFI\_FLUI\_STRU [U4.25.01]).*

*To carry out a calculation with several zones of excitation, it is necessary to define as many spectra as there is*

*zones. The contributions of the various spectra can be then added when the excitation is projected on modal basis by order PROJ\_SPEC\_BASE [U4.63.14]. However, it is not possible in this order to combine spectra of the type "length of correlation" with spectra of another type (SPEC\_CORR\_CONV\_n, SPEC\_FONC\_FORME or SPEC\_EXCI\_POINT).*

*The four spectra of the type "length of correlation" have values defined by defect. The definition new coefficients is delicate, in particular with regard to the model 3 for which it exist conditions of connection between the lines determined by the coefficients.*

*The general analytical form of models 1 to 4 is as follows:*

*- S*

*2 - S*

*S (S*

*1*

*1, S, F*

*2*

*R) = S (F R) .exp*

*C*

*with:*

*S (S, S, F*

*interspectre adimensional of turbulence between two points of X-coordinates*

*1*

*2*

*R)*

*curvilinear S, S*

*1*

*2 ;*

*S (F*

*autospectre of turbulence;*

*R)*

-  $S$

2 -

$S$

*exp*

1

*function of space correlation and  $C$  length of correlation.*

$C$

*The spectrum is defined according to a reduced frequency  $Fr$  (a Strouhal number). For a tube under transverse flow, the  $Fr$  expression is as follows:*

$F$ .  $E$

$D$

$F R =$

$G$

$V$

*$F$  is the dimensioned frequency, of the diameter external of the tube and  $Vg$  transverse speed average of the fluid along the structure, which will be recovered in operator  $PROJ\_SPEC\_BASE$  [U4.63.14] via the concept [melasflu] produced by operator  $CALC\_FLUI\_STRU$  [U4.66.02].*

### ***3.2.2 Definition of a spectrum of turbulence of a function of the frequency unspecified***

/  
***SPEC\_CORR\_CONV\_2***

*Key word factor allowing to define a spectrum of unspecified pressure function of frequency.*

***FUNCTION***

=

***fonc***

*Concept of the function type defining the spectrum of pressure according to frequency, produced by one of operators **DEFI\_FONCTION** [U4.31.02], **CALC\_FONCTION** [U4.32.04] or **CALC\_FONC\_INTERP** [U4.32.01].*

***VITE\_FLUI***

=  
*vflui*

*Speed of the fluid skirting the studied structure.*

*FREQ\_COUP*  
=  
*FC*

*Frequency cut-off beyond which the function defining the spectrum of pressure is regarded as null.*

*COEF\_VITE\_FLUI\_A = alpha*

*Coefficient the convective speed of the swirls in the axial direction (direction of the flow).*

*METHOD*  
=  
*“CORCOS”*

*Method of correlation for the structures of the type plates. Lengths of correlation reserves are the lengths of the model of CORCOS per defect (see [§3.2]).*

### **3.3 Key word**

***SPEC\_FONC\_FORME***

/  
*SPEC\_FONC\_FORME*

*Key word factor allowing to define a spectrum of excitation by its decomposition on one family of functions of form.*

*/INTE\_SPEC*  
=  
*int\_spec*

*Concept of the tabl\_intsp type defining a matrix interspectrale excitation. It concept can be produced by operator LIRE\_INTE\_SPEC [U4.36.01] after reading matrix interspectrale on external file.*

*FUNCTION = l\_fonc*

*List concepts of the function type defining the family of functions of form*

*associated.*

/  
*GRAPPE\_1 = "DEBIT\_180" or "DEBIT\_300"*

*Two possible choices corresponding to the flows for which excitation GRAPPE1 was identified.*

*NODE*

=  
*No*

*Node of application of the excitation.*

*Instruction manual*

*U4.4- booklet: Modeling HT-66/05/004/A*

---

***Code\_Aster*** ®

*Version*

*U4.44.31-E Page*

*: 11/12*

***CARA\_ELEM***

=

*will cara*

*Concept of the cara\_elem type produces by operator AFFE\_CARA\_ELEM [U4.42.01], defines geometrical characteristics assigned to the elements of the structure.*

*The geometrical characteristics are necessary to the estimate of the diameter hydraulics. Moreover, the concept of the cara\_elem type brings relative information with the orientations of the elements.*

***MODEL = model***

*Concept of the model type produced by operator AFFE\_MODELE [U4.41.01], defines them types of elements assigned to the meshes of the structure.*

**Note:**

*1) The length of application  $L$  is characterized in an intrinsic way by field of definition of the functions of form associated with the excitation. The zone of application is centered around the node of application.*

*2) The turbulent excitation being able to be developed in a way correlated in both orthogonal directions with the axis of the telegraphic structure (axis  $\mathbf{X}$ ), functions of form are a priori vectors with two components (according to  $\mathbf{y}$  and  $\mathbf{Z}$ ).*

*One will thus inform, by convention, these functions about the interval  $(0; 2L)$ , them fields  $(0; L)$  and  $(L; 2L)$  being respectively associated with the directions  $\mathbf{y}$  and  $\mathbf{Z}$ .*

**3.4 Key word**

**SPEC\_EXCI\_POINT**

/  
SPEC\_EXCI\_POINT

*Key word factor allowing to define a spectrum of excitation associated with one or more forces and specific moments.*

/INTE\_SPEC  
=  
int\_spec

*Concept of the tabl\_intsp type defining a matrix interspectrale excitations specific. This concept can be produced by operator LIRE\_INTE\_SPEC [U4.56.01] after reading of the matrix interspectrale on external file.*

NATURE  
=  
l\_nat

*List arguments of the text type defining the nature of the excitation of each one of nodes of application. The licit arguments are "FORCE" or "MOMENT".*

ENG  
=  
l\_theta

*List angles defining the directions of the vectors forces and moments in each node of application (see diagram).*

**Z**  
**P**  
**RF**

y  
*Node of application*  
*X (neutral fibre)*

*Author (S):*  
**A. Key ADOBES**  
:  
*U4.44.31-E Page*  
: 12/12

*The vector force is directed in the plan **P** orthogonal with neutral fibre. In this plan, the azimuth gives the direction of the vector. The angles must be given in **degrees**.*

**NODE**  
=  
*l\_no*

*List nodes of application of the specific excitations.*

**Note:**

*The matrix interspectrale has as a dimension the number of forces and moments specific applied. The diagonal terms of this matrix characterize them autospectres of these excitations.*

*Lists defining the nodes of application, the nature and the direction of imposed excitations must thus be ordered in accordance with the structure matrix interspectrale of excitations.*

/

**GRAPPE\_2**

=

“ASC\_CEN” or “ASC\_EXC” or “DES\_CEN” or “DES\_EXC”

*Four possible choices corresponding to the various experimental configurations for which excitation GRAPPE2 was identified:*

- Ascending flow stem of Centered order,
- Ascending flow stem of Offset order,
- flow Descending stem from Centered order,
- flow Descending stem from Offset order.

*Excitation GRAPPE2 is characterized by a specific force and a moment applied in the same node, in a homogeneous way in the two directions orthogonal with the axis of the telegraphic structure.*

**RHO\_FLUI**

=

*rho\_f*

*Density of the fluid surrounding the structure.*

**NODE**

=

*No*

*Node of application of excitation GRAPPE2.*

**Note:**

*When one resorts to a preset spectrum GRAPPE2, the list of nodes waited under the operand **NODE** is reduced to only one element (only one node of application).*

**CARA\_ELEM**

=

*will cara*

*Concept of the cara\_elem type produces by operator AFFE\_CARA\_ELEM [U4.42.01], defines the affected geometrical characteristics in the elements of the structure. The geometrical characteristics are necessary to the estimate of the diameter hydraulics. Moreover, the concept of the cara\_elem type brings information relating to the orientations of the elements.*

*MODEL = model*

*Concept of the model type produced by operator AFFE\_MODELE [U4.41.01], defines them types of elements assigned to the meshes of the structure.*

***Key word SOLVEUR***

### ***1 Goal***

***To choose the mode of storage of the matrices and the algorithm of resolution. This key word factor is found in a certain number of orders leading to the resolution of linear systems. For algorithms of resolution it makes it possible to choose between “traditional” factorization of type “GAUSS” (“LDLT”), multi-frontal factorization (“MULT\_FRONT” or “MUMPS”), combined gradient packaged ILU (K) (“GCPC”) or solver FETI by decomposition of fields (“FETI”).***

***For each type of solver, certain optional numerical parameters are accessible and are described here. By defect, it is the solver “MULT\_FRONT” who is used. Solver “FETI”, as for him, is still in phase of development, it is thus not advised to use it without preliminary councils of the team of development.***

### **3 Operands**

#### **3.1 Operand**

##### **METHOD**

**METHOD =**

*This key word makes it possible to choose the method of resolution of the linear systems:*

*/"MULT\_FRONT" direct Solveur of type "multi-frontal". Matric storage is "MORSE" (defect)*

*and thus proscribed any swivelling. This method is paralleled in memory divided (OpenMP) and can be carried out on several processors (via small the Astk interface Options Options of launching). The initial matrix is stored in only one object JEVEUX and its factorized is distributed on several, therefore can be discharged partially and automatically on disc.*

*/"LDLT"*

*Direct Solvor with factorization of Crout per blocks (without swivelling). matric storage is "line of sky" or "SKYLINE". There is a pagination completely skeletal memory (the matrix is broken up in blocks managed in memory independently and discharged on disc progressively) which makes it possible to pass from large case but which pay by accesses expensive discs.*

## ***/“MUMPS”***

***Direct Solvor of type “multi-frontal” with swivelling. This solvor is obtained while “connecting” on library MUMPS developed by CERFACS-ENSEEIH-Parallab (see lower copyright). For Code\_Aster, its interest principal resides in its capacity to swivel lines and/or columns of the matrix during factorization in the event of small pivot.***

***This possibility is useful (even essential) for the models leading to positive nondefinite matrices (except conditions to limits); for example, “mixed” elements having ddls of the type “Lagrange” (incompressible elements...).***

***By means of computer, this solvor poses two problems: he requires one compiler fortran90 and it are necessary to share the memory between JEVEUX and library MUMPS (use of the button “mem\_aster” of small the OPTIONS ASTK).***

## ***/“GCPC”***

***Iterative Solvor of gradient type combined with prepacking ILU (K). The storage of the matrix is then “MORSE”. The initial matrix and its factorized incomplete are stored, each one, in only one object JEVEUX.***

## ***/“FETI”***

***Solvor by decomposition of fields of the type FETI: combined gradient packaged projected (GCPPC) for the problem of interface and solvor direct multi-frontal for the inversions of the local matrices of rigidity. Local problems being reversed by multi-frontal “the MULT\_FRONT”, their associated matrices, local and factorized matrices of rigidity, are treated like such (cf above). This method is paralleled in distributed memory (MPI).***

***The default values of the other key words are then taken automatically according to selected method.***

### 3.2

#### **METHOD: "MULT\_FRONT"**

*RENUM =*

*This argument makes it possible to renumber the nodes of the model:*

*/"MANDELEVIUM"*

*("Degree Minimum") this classification of the nodes minimizes the filling of stamp during its factorization.*

*/"MDA"*

*("Approximate Degree Minimum") this classification is in theory less optimal than "MANDELEVIUM" with regard to the filling but it is more economic with to calculate. It is however preferable with "MANDELEVIUM" for the large models (50 000 ddls).*

*/"MONGREL" Another method of classification based on an encased dissection. This method (defect) is not possible that on the waiter of calculation dedicated to the project Aster (Alpha Waiter TRU64) except installing oneself the achievable MONGREL. On this machine, it is the most effective method (in time CPU and memory).*

*STOP\_SINGULIER = "YES" (defect)/"NOT"*

*When at the end of factorization, one notes that a diagonal term of became very small (compared to what it was before factorization D), it is that the matrix is (probably) almost singular.*

*D*

*That is to say  $N = \log$ , this report/ratio magnitude indicates that on an equation (at least) one lost N of significant figures.*

*If  $N > nprec$  (key word NPREC below), one considers that the matrix is singular. If the user indicated: STOP\_SINGULIER = "YES", the code stops then in FATAL ERROR, if not the execution continues with emission of an alarm.*

**Note:**

*Any important loss of significant figures during a factorization is an indicator of one badly posed problem. Several causes are possible (nonexhaustive list):*

.  
*boundary conditions insufficient of blocking of the structure,*

.  
*redundant linear relations,*

.  
*very heterogeneous numerical data (too large terms of penalization),...*

*NPREC = nprec (défaut=8)*

*It is the number which is used to determine if the matrix is singular (or not) (cf key word STOP\_SINGULIER above).*

### **3.3**

#### **METHOD: “LDLT”**

*RENUM =*

*This argument makes it possible to renumber if it is wished the nodes of the model:*

*“WITHOUT”*

*One keeps the initial order given in the file of grid,*

*“RCMK”*

*“Reverse Cuthill-MacKee”, this algorithm of renumerotation is often effective (defect) to reduce the place necessary to storage “line of sky” of the assembled matrix and to reduce time necessary to the factorization of the matrix.*

*STOP\_SINGULIER*

*See [§3.2].*

*NPREC*

*See [§3.2].*

*Instruction manual*

### **3.4**

#### **METHOD: "MUMPS"**

##### **3.4.1 General**

*Solvor MUMPS developed by CERFACS-ENSEEIH-Parallab is a direct solver of type multi-frontal paralleled (MPI) and robust because it makes it possible to swivel the lines and columns of the matrix during numerical factorization.*

*Although he is a direct solver, its use in Code\_Aster is connected more with the iterative solver GCPC: one cannot use it in the operator modal nor in conjunction of the key word STOP\_SINGULIER='DECOUPE'.*

*The reason is that MUMPS (called by Code\_Aster) does not give information on the quality of factorization (as MULT\_FRONT and LDLT do it: to see key word NPREC). One thus does not know to determine if a matrix is "close" to the singularity during its factorization.*

##### **3.4.2 TYPE\_RESOL**

*This key word makes it possible to choose the type of resolution MUMPS:*

*"NONSYM" must be selected for the nonsymmetrical matrices.*

*"SYMGEN" must be selected for the positive nondefinite symmetrical matrices. It is the case more general in Code\_Aster because of dualisation of the boundary conditions by coefficients of Lagrange.*

*"SYMDEF" can be selected for the positive definite symmetrical matrices. There is no swivelling.*

*If the user leaves the default value ("CAR"), the code will not choose "NONSYM" for the matrices symmetrical and "SYMGEN" for the symmetrical matrices.*

*It is not interdict to choose "NONSYM" for a symmetrical matrix. That will probably double it*

*cost of calculation but this option gives to MUMPS more possibilities of swivelling while breaking initial symmetry.*

### **3.4.3 RESI\_RELA**

*This key word makes it possible to choose the precision awaited for the resolution. This value is the relative residue acceptable maximum (1.d-6 by defect). If this precision is not reached, the code stops in fatal error.*

### **3.4.4 PCENT\_PIVOT**

*This key word makes it possible to choose a percentage of memory that MUMPS will hold at the beginning of calculation for its swivellings. The default value is 20% which corresponds to a number of swivellings reasonable. If for example MUMPS estimates at 100 the place necessary to a factorization without swivelling, it will allocate actually 120. Thereafter, if the number of swivellings is more important than envisaged, the place allocated memory will be insufficient and the code will stop in fatal error while requiring to increase PCENT\_PIVOT. For certain calculations, it is necessary "to push" PCENT\_PIVOT up to 500! what wants to say that the overcost of the swivelling is 500%.*

*U4.50.01-F1 Page:*

*9/14*

*If niv = 0*

*P has same storage that A. factorization is incomplete because one does not use for calculations that the terms which one can store in A.P thus represents an approximation (poor) of AI; its storage is thus more reasonable.*

*If niv = 1*

*One stores in P in addition to the terms which had their place in initial storage, them "downward" of first generation of the initial terms. Indeed during factorization, one null term in A can become nonnull in P. One obtains thus the filling of level 1.*

*If niv = 2,...*

*The same process is taken again: the matrix P filled on the level niv-1 creates the terms of stamp P on the level niv.*

*The larger niv is, the closer the matrix P is to AI and thus more the combined gradient converge quickly (in iteration count). On the other hand, more niv is the great more storage of P becomes bulky (in memory and on disc) and more the iterations are expensive in CPU. The first tests showed (roughly) that the size of P was worth:*

*.  
1\*taille (A) for niv = 0*

*.  
3,5\*taille (A) for niv = 1*

*.  
7,5\*taille (A) for niv = 2*

*Our experiment of this key word is still limited and we advise to use the value by defect (niv = 0). If niv = 0 does not allow the gradient combined to converge, one will test successively the values niv = 1, 2, 3...*

*NMAX\_ITER*

*= niter*

*(défaut=0)*

*SCALING*

=

*This argument makes it possible to choose the type of scaling (put on the scale) adoptee for preconditionnor. It is thus taken into account only if PRE\_COND is different from “WITHOUT”.*

*“WITHOUT”*

*No the phase of scaling.*

“MULT”

*Scaling by the multiplicity of the nodes of interface.*

**(defect)**

*Normally the phase of scaling leads to a profit in iterations and CPU, without overcost memory. Especially when partitioning produces many assemblage points (points belonging to more than two under-fields).*

TYPE\_REORTHO\_DD

=

*This argument makes it possible to choose the type of reorthogonalisation of the directions of descent (to the centre*

*of a resolution of system linear or between various resolutions cf ACCELERATION\_SM). It is related to parameter NB\_REORTHO\_DD.*

“WITHOUT”

*No the reorthogonalisation of the methods of descent.*

“GS”

*Réorthogonalisation of Gram-Schmidt.*

“GSM”

*Réorthogonalisation of Modified Gram-Schmidt.*

**(defect)**

“IGSM”

*Réorthogonalisation of Iterative Modified Gram-Schmidt.*

*This phase makes it possible to fight against the propensity of the directions of descent of the GCPPC to lose*

*their orthogonality. In theory, IGSM is better than GSM which is him even higher than GS. In practical, the best compromise “overcost calculation/quality of orthogonality” is often carried out by GSM.*

NB\_REORTHO\_DD = nb\_reortho (**défaut=0**)

*A number of initial directions of descent used in the phase of reorthogonalisation. In principle, more it is large, better is convergence, but greater east also the overcost calculation and memory. It is thus necessary to find a compromise between these elements.*

*If nb\_reortho = 0 then this number is calculated as follows:*

*nb\_reortho = max (niter/10,5) where niter the maximum number of definite iterations above.*

RENUM

*See [§3.2].*

## *STOP\_SINGULIER*

*See [§3.2].*

## *NPREC*

*See [§3.2].*

*VERIF\_SDFETI = “YES” (defect)/“NOT”*

*One enters the inconsistencies in term of name of model and of names of loading, enters the parameter setting of the operator calling the key word SOLVEUR and that provides to the operator partitioning which remains stored in the SD\_FETI. It is necessary that the names of models are identical and that the list of the loadings of the appealing operator is included in that of DEFI\_PART\_OPS. If it is not the case and if VERIF\_SDFETI = “YES”, one stops in ERREUR\_FATALE, if not an ALARM is emitted.*

## *TEST\_CONTINU*

*= test\_continu*

*(défaut=10-6)*

*Criterion of the test of continuity to the interface: it is a relative criterion on the values (nonnull) of unknown factors with the interface. If one is in top of the criterion, it y' has emission of an ALARM.*

*STOCKAGE\_GI = "CAL" (defect)/"YES"/"NOT"*

*When the number of under-fields increases, an object becomes prominent, it is **GI** the matrix traces of the rigid modes of body on the interface. It is used in the phase of projection, i.e.  $10 + \text{nombre\_itérations\_FETI} * 4$ . To allow the user to adapt it compromise "cuts memory/time CPU", its storage is skeletal:*

- If STOCKAGE\_GI = "YES", it is calculated and stored once for all. That require more memory but less time calculation when one makes use of it.*
- If STOCKAGE\_GI = "NOT", it is the reverse, it is recomputed with each time that is necessary.*
- If STOCKAGE\_GI = "CAL", the choice "YES" or "NOT" will be calculated automatically. If the size of the matrix is lower than the average size of the local matrices of rigidity, one store ("YES"), if not, one recomputes ("NOT").*

*INFO\_FETI = info\_feti (défaut=' FFFFFFFFFF')*

*Its pre, character string allowing to parameterize postings of algorithm FETI and postprocessings as well as its tests of coherence. This monitoring is independent of the key word INFORMATION. Being often very verbeux and sometimes expensive in memory and CPU, it must be used of*

*preference on small cases and rather for activities of developments.*

- If INFO\_FETI (1: 1) = ' You: general unfolding of the algorithm.*
- If INFO\_FETI (2: 2) = ' You: contents of the structures of data except CHAM\_NO and MATR\_ASSE.*
- If INFO\_FETI (3: 3) = ' You: contents of the structures of data CHAM\_NO and MATR\_ASSE.*
- If INFO\_FETI (4: 4) = ' You: posting of intermediate variables.*
- If INFO\_FETI (5: 5) = ' You: details of the routines of assemblies.*
- If INFO\_FETI (6: 6) = "You: tests of validity of the modes of rigid bodies.*
- If INFO\_FETI (7: 7) = "You: test of the definite-positivity of the operator of interface. One calculate then the  $n_{\text{max\_freq}} = \min(n_{\text{bi}} - 2, n_{\text{b\_reortho}})$  eigenvalues via the algorithm IRAM [R5.01.01] while projecting on a space of size  $\text{dim\_sous\_espace} = \min(n_{\text{bi}}, n_{\text{iter}})$ . Option sells by auction only into sequential.*
- If INFO\_FETI (8: 8) = "You: test of orthogonalities of the GCPPC.*
- If INFO\_FETI (9: 9) = "You: profiling (time CPU + system) of the various stages of resolution of the problem of interface FETI, the GCPPC, (projection, operator FETI, reorthogonalisation, restartings...).*
- If INFO\_FETI (10: 10) = "You: postings dedicated to parallelism MPI.*
- If INFO\_FETI (11: 11) = "You: general postings (size of the interface, the matrices of rigidity local and their factorized, a total number of rigid modes...) and profiling stages upstreams of solvor FETI (time CPU + system of the phases of calculations*

*elementary, of assemblies, factorizations symbolic system and numerical) detailed by under-field or by processor.*

*NB\_SD\_PROC0 = nb\_sdproc0 (défaut=0)*

*Parameter used in parallel mode MPI, allowing to allot a number of under-fields arbitrary with processor 0 (the “Master”). This number can thus be lower than that which would be to him*

*allotted by the automatic procedure of distribution “under-fields/processors”. That allows to relieve it, in CPU and memory capacity, compared to the other processors because it must to manage additional stages and potentially bulky objects JEVEUX (phase of reorthogonalisation, projections of the coarse problem...).*

*It is active only if it is licit:  $nb\_sdproc0 > 0$  and  $nb\_sdproc0 < nbsd - nbproc + 1$  ( $nbproc$ , a number of processors and  $nbsd$ , a number of under-fields).*

**ACCELERATION\_SM**

=

*This argument makes it possible to activate the phase of acceleration of a problem with multiple second members (for example, a calculation of elasticity with thermal loadings depending on time). When it is activated, the GCPPC of solver FETI will not start its process in on the basis of zero, but on the contrary will be based on information a priori, that of the directions of descent stored with the nb\_reortho\_inst not of previous times. One thus will gain much in iteration count and thus in CPU, by conceding little in memory enough (if the interface is weak in front of the size of the problem).*

“YES”

*Activated acceleration if the conditions are met (see low).*

**(defect)**

“NOT”

*Decontaminated acceleration.*

*This argument is related to parameter NB\_REORTHO\_INST and is activated only if the problem is one succession of linear systems to second members different and if the reorthogonalisation from directions of descent, within each step of time, is activated (TYPE\_REORTHO\_DD different from “WITHOUT”).*

**NB\_REORTHO\_INST = nb\_reortho\_inst (défaut=0)**

*With a step of time given, it is the number of steps of previous times which one will use them directions of descent for the procedure of acceleration. In theory, more it is large, better is convergence, but greater east also the overcost calculation and memory. One thus should be found compromise between these elements.*

If  $nb\_reortho\_inst = 0$  then this number is calculated as follows:

$$nb\_reortho\_inst = \max(nb\_pas\_temps/5, 5)$$

where  $nb\_pas\_temps$  is the number of steps of time of the problem.

And if, with the step of time  $num\_pas\_temps$ ,  $nb\_reortho\_inst$  is higher than the number of steps of previous times available (e.g. to the 5<sup>ième</sup> not of time one can use only the 4 steps of former times) one dynamically fixes it at this value:

$$nb\_reortho\_inst = num\_pas\_temps - 1.$$

### 3.7 Word

key

**SYME**

*SYME*

=

/“YES”

/

“NOT”

If the matrix of linear system **A** is not-symmetrical, the key word **SYME** = “YES” allows to symmetrize this matrix before the resolution of the system. The matrix then is replaced by

1

$A' = ($

$T$

**WITH** + **A**).

2

#### **Caution:**

The symmetrization of matrix **A** thus results in solving another problem that that which one seeks to solve! Actually, this possibility (**SYME** = “YES”) is useful only in non-linear orders (like **STAT\_NON\_LINE** for example), for which convergence towards the solution is obtained by successive iterations. Each reiterated is obtained by “estimate” and one checks then that it is “solution”. In this case, a light error on reiterated does not prevent from converging towards the good solution. The interest of this key word is of

to save time at the time of the resolution of the linear systems. The whole is to know if does symmetrization disturb much (or not) the solution of the linear system? One can quote (by example) the case of the models 3D (or hull) with following pressure for which symmetrization saves much time.

### 3 Operand

***SENSITIVITY***

***SENSITIVITY =***

***This key word makes it possible to choose the parameters by report/ratio to which one derives the result.***

***They are significant parameters, defined by order DEFI\_PARA\_SENSI (cf document [U4.31.04]):***

*ps1,  
ps2,... [l\_para\_sensi]*

*That can also be fields theta in the case of derivation compared to the field geometrical:*

*theta1, theta2,... [l\_theta\_geom]*

*The key word SENSITIVITY can be followed of 1 or several names of parameters. Their order is indifferent. On the other hand, the key word itself can be present only once in order.*

#### **4 Convention of drafting**

*We will review the three types of operators who accept the key word SENSITIVITY: main line operator, of enrichment, postprocessing.*

*Main line operator: it is an operator who carries out the resolution of the problem and creates one new structure of result. They are the THER\_LINEAIRE, MECA\_STATIQUE, etc In it case, the insertion of the key word SENSITIVITY means that Code\_Aster will calculate the result usual, but also each one of derived from this result compared to each one of parameters transmitted by the key word.*

*Operator of enrichment: it is an operator who starting from the principal result (temperature, displacement,...) product of the secondary results (flow, forced,...). They are them operators CALC\_ELEM and CALC\_NO for example. In this case, the insertion of the key word SENSITIVITY means that Code\_Aster will calculate the derivative of the secondary result by report/ratio with each parameter transmitted by the key word.*

*Operator of postprocessing: it is an operator who does not make calculation but which puts in form a result to make it available to the user. They are the operators POST\_RELEVE\_T, IMPR\_RESU for example. In this case, the insertion of the key word SENSITIVITY means that Code\_Aster will exploit the derivative of the result compared to each parameter transmitted by the key word. Attention, only these derivative are exploited.*

*In the continuation of this document, we will enumerate the operators concerned with the sensitivity.  
By*

*convention, only the operators mentioned hereafter are concerned. In the same way, for an operator given, only the types of derivations mentioned are accessible.*

*Unless otherwise specified, all the derivative accessible are it for all the types of elements, for all types of model and as well in hover as in transient.*

*U4.50.02-C1 Page:*

*4/12*

*5*

*In a main line operator*

*5.1 General*

*The main line operator calculates the principal result and his derivative.*

*Example:*

```
reth = THER_LINEAIRE  
(MODEL = model,  
CHAM_MATER = chmat,  
EXCIT = (...),  
SENSITIVITY = (ps1, ps2));
```

*This sequence will solve a linear problem of thermics and will produce the structure of result reth. This structure contains the field of temperature TEMP. Moreover, there will be calculation of derived from*

*the temperature compared to ps1 and of derived from the temperature compared to ps2. These derivative*

*have same nature as the temperature: they are represented in the shape of fields to the nodes. These fields are then easy to handle like the usual field of temperature: extraction of values, impressions, etc*

*In a subjacent way, there is creation of as many structures of results of sensitivities asked. Their names are established automatically by the program. They do not have to be known explicitly because one will always accèdera with information by a couple (name of standard result, name parameter of sensitivity). Each field which makes one of these structures of results the derivative of this field compared to the parameter of sensitivity concerned will contain.*

*Example:*

*The field TEMP of the structure reth of the evol\_ther type contains the field of temperature with nodes of standard calculation. The field TEMP of the structure of the evol\_ther type known by the couple (reth, ps1) the field with the nodes of the derivative partial of the temperature will contain compared to*  
*T*

*ps1,*  
*. The same rule applies to all the fields which will be calculated by enrichment.*  
*1*  
*PS*

## *5.2 Operator*

### *THER\_LINEAIRE*

#### *5.2.1 By*

*ameters*  
*sensitive*

*It is possible to derive the field from temperature compared to a significant parameter when it was used to define:*

*.  
a condition of imposed temperature,*

*.  
a loading:*

*- source,  
- flow,  
-*

*coefficient of exchange and outside temperature,*

-  
*coefficient of walls exchange,*

*a material:*

- *conductivity*

*thermics*

,  
- *heat*

*voluminal*

*5.2.2 Derivation*

*Lagrangian*

*Derivation known as “Lagrangian” makes it possible to calculate the sensitivity of the field of temperature*

*position of the edge of the field. That is not possible that for modelings “PLAN” and “AXIS”.*

*The edge by report/ratio to which one wishes to derive the temperature must be rectilinear, parallel to the axis of*

*y. The matter must be “on the right” of this edge.*

*y*

*Edge*

*Matter*

*The designation of this edge is made by the data of a field “theta”:*

*SENSITIVITY = (theta)*

*This field is defined by operator CALC\_THETA, by using option THETA\_BANDE to give position of the edge cf [U4.82.02].*

*Note:*

*There is no checking of coherence between the data of the X-coordinate of the edge in definition of the field theta and the position of the edge such as it is defined in the grid. One will look at the test [V7.01.101] for an example of Lagrangian derivation in thermics.*

*5.3 Operator*

*THER\_NON\_LINE*

*It is possible to derive the field from temperature compared to a significant parameter when it was used to define:*

•  
*a condition of imposed temperature,*

•  
*a loading:*

- *source,*

-  
*linear and nonlinear flow,*

- *emissivity,*

- *temperature*

*with*

***Derivation is available for the isoparametric finite elements and following modelings:  
PLAN, PLAN\_DIAG, AXIS, AXIS\_DIAG, 3D and 3D\_DIAG.***

***Note:***

***One will look at the test [V1.01.154] for an example of sensitivity in non-linear thermics.***

## ***5.4 Operator MECA\_STATIQUE***

### ***5.4.1 Parameters sensitive***

***It is possible to derive the field from displacement compared to a significant parameter when it was used to define:***

- a condition of imposed displacement (DDL\_IMPO or FACE\_IMPO),***
- a loading:***
  - a pressure distributed,***
  - a force nodal or distributed linear,***
- a material:***
  - Young modulus for an isotropic, orthotropic elastic law or isotropic-transverse.***
  - Poisson's ratio***

***The functionality of derivation is available in 2D and 3D, isothermal continuous medium, POU\_D\_E.***

***Note:***

***One will look at the test [V1.01.144] for an example of sensitivity in static mechanics.***

### ***5.4.2 Derivations Lagrangian***

***Derivation known as “Lagrangian” applies under the same conditions as for the operator of linear thermics. Only additional restriction: the elements must be degree 2.***

***Note:***

*One will look at the test [V7.01.101] for an example of Lagrangian derivation in mechanics.*

## **5.5 Operator**

**MODE\_ITER\_SIMULT and MODE\_ITER\_INV**

*It is possible to derive the clean, real or complex modes, compared to a significant parameter when it was used to define:*

.

*a condition of imposed displacement,*

.

*a material (available in 2D and 3D, continuous medium, POU\_D\_E):*

*- module*

*of Young,*

-

*Poisson's ratio.*

*The functionality of derivation of the clean modes is not available for the multiple modes.*

**Note:**

*One will look at the test [V1.01.188] for an example of sensitivity of clean modes.*

## **5.6 Operator**

### **STAT\_NON\_LINE**

*It is possible to derive the field from displacement, constraints and internal variables by report/ratio with a significant parameter when it was used to define:*

- 
- a condition of imposed displacement (DDL\_IMPO or FACE\_IMPO),*
- 
- a condition of the Neumann type:*
  - 
  - a pressure distributed,*
  - 
  - a force nodal or distributed linear,*
  - 
  - a material:*
    - *module of Young*
    - 
    - Poisson's ratio*
    - *limit of elasticity*
    - 
    - slope of the traction diagram after the elastic limit*

*The functionality of derivation is available only for one elastic or elastoplastic structure (Von Mises or Drucker-Prager) with isotropic linear work hardening, in 2D and 3D, continuous medium isotherm, POU\_D\_E (only on the Young modulus and the Poisson's ratio). It available in 2D is not forced plane.*

*Note:*

*One will look at the test [V1.01.181] for an example of sensitivity in static mechanics non-linear.*

## **5.7 Operator**

### **DYNA\_LINE\_HARM**

*It is possible to derive the field from displacement compared to a significant parameter when it was used to define:*

- *a condition of imposed displacement,*
- *a loading:*

- *force nodal,*  
-  
*force distributed linear, surface or voluminal,*  
- *pressure distributed.*

·  
*a material (available in 2D and 3D, continuous medium, POU\_D\_E):*

-  
*Young modulus for an isotropic, orthotropic elastic law or isotropic-transverse,*  
-  
*Poisson's ratio.*

*Note:*

*One will look at the test [V1.01.158] for an example of sensitivity in linear dynamics harmonic.*

## *5.8 Operator DYNA\_LINE\_TRAN*

*It is possible to derive the field from displacement compared to a significant parameter when it was used to define:*

· *a condition of imposed displacement,*  
· *a loading:*  
- *force nodal,*  
-  
*force distributed linear, surface or voluminal,*  
- *pressure distributed,*

·  
*a material (available in 2D and 3D, medium continuous, POU\_D\_E, inalienable for the diagram of integration clarifies with step of adaptive time):*

-  
*Young modulus for an isotropic, orthotropic elastic law or isotropic-transverse,*  
-  
*Poisson's ratio.*

*Note:*

*One will look at the test [V1.01.171] for an example of sensitivity in linear dynamics transient.*

## **6 In an operator of enrichment**

### **6.1 General**

**The operator of enrichment calculates secondary results starting from the principal result.**

**Example:**

```
reth = CALC_ELEM  
(RESULT = reth,  
MODEL = model,  
EXCIT = (...),  
OPTION = ("FLUX_ELGA_TEMP"),  
SENSITIVITY = (ps1, ps2)),
```

**This sequence will enrich the structure of reth results by calculating the derivative by the heat flux with**

**points of Gauss compared to ps1 and that compared to ps2.**

**These derivative have same nature as flow: they are fields at the points of Gauss. These fields are then easy to handle like the field of usual flow: extraction of values, impressions, etc**

**Note:**

*For making such an enrichment, it is necessary that the derivative of the principal field (temperature, displacement,...) was calculated.*

*The arrangement of the various derived fields is done according to the rule described with [5.1].*

## **6.2 Operator CALC\_ELEM**

**The operator of enrichment calculates secondary results starting from the principal result.**

### **6.2.1 Parameters sensitive**

**In or not linear linear thermics:**

•  
**FLUX\_ELGA\_TEMP: derived from the heat flow.**

**In static mechanics:**

•  
**EPSI\_ELGA\_DEPL: derived from the deformations,**  
•  
**SIEF\_ELGA\_DEPL: derived from the constraints.**

**In transitory linear dynamics:**

•  
**\*\*\*\* \_ \*\*\*\* \_DEPL: derived from the strains or the stresses.**

### **6.2.2 Derivation Lagrangian**

**In linear thermics:**

•  
**DETE\_ELNO\_DLTE: derived eulérienne from the temperature.**

**In static mechanics:**

•  
**DEDE\_ELNO\_DLDE: derived eulérienne from the temperature,**  
•  
**SIEF\_ELGA\_DEPL: Lagrangian derivative of the constraints,**  
•  
**DESI\_ELNO\_DLSI: derived eulérienne from the constraints.**

## **6.3 Operator CALC\_NO**

**There is no particular restriction: as from the moment when the derivative by element was calculated, its projection on the nodes is possible.**

**6.4 Operator**

**NORM\_MODE**

**It is a question here of multiplying the derivative of the clean vector by a coefficient depend on the standard asked by the user.**

**6.5 Operator**

**CALC\_G\_THETA\_T**

**The rate of refund of energy can be derived. The field of validity is that of the derivation of fields of displacements and associated constraints.**

**It is possible to derive the rate of refund from energy compared to a significant parameter when it has summer used to define:**

.

**a loading:**

-

**a force distributed linear (2D) or surface (3D),**

- a voluminal force (2D or 3D),
- a pressure distributed on the lips of the crack,
- a nodal force,
- a material:
- Young modulus for an isotropic elastic law.

### Limitations:

- It is not possible to derive the rate of refund from energy compared to a condition from imposed displacement because the term corresponding in G is not established.
- The functionality of derivation is available in 2D and 3D, medium continuous.

The result is a table, like the rate of standard refund.

### Example:

`ga = CALC_G_THETA_T (...  
SENSITIVITY = (ps1, ps2)),`

This sequence will produce the derivative of the rate of refund `ga` compared to the significant parameter `ps1`.

The exploitation of this derivative will be done by providing the couple (`ga`, `ps1`); for example, for one impression one will use usual order `IMPR_TABLE`.

### Note:

*One will look at the test [V7.02.101] for an example of sensitivity in breaking process.*

**U4.50.02-C1 Page:**

**11/12**

**7**

**In an operator of postprocessing**

## **7.1 General**

**The operator of postprocessing formats the derivatives of the results.**

**IMPR\_RESU (RESU = \_F (GRID = email,  
RESULT = reth,  
NOM\_CHAM = "TEMP"  
SENSITIVITY = (ps1, ps2)) ),**

**This sequence will print the derivative of the field of temperature contained in the reth result compared to ps1 and ps2. Attention, that will not print the standard temperature.**

**One notes in these orders that the name of the structure of results which contains the derivative never appears in light. The structure is always known by the couple (name of standard result, name of the significant parameter). It is what is described with [§5.1].**

## **7.2 Operators concerned**

**The postprocessing of derivations of the results is possible with the following operators:**

.

**IMPR\_RESU: impression of structures of results,**

.

**IMPR\_TABLE: impression of tables,**

.

**POST\_RELEVE\_T: extraction of values,**

.

**TEST\_RESU: comparison of values,**

.

**EXTR\_RESU: extraction of results,**

•  
**CREA\_CHAMP: creation of a field.**

***Operator MECA\_STATIQUE***

## ***1 Goal***

***To solve a problem of static mechanics linear.***

***This operator allows to solve is:***

***.  
a linear static mechanical problem with superposition of various conditions with limits and of various loadings,  
.***

***a thermomechanical analysis for a given list of moments.***

***-  
in this case the mechanical characteristics of materials can depend on temperature: the concept of the `cham_mater` type must then be defined starting from functions (Cf operator `DEFI_MATERIAU` [U4.43.01] operand `ELAS_FO`),  
-***

***the loading of dilation can be given only if one defined the coefficient of dilation and the temperature of reference (cf operators `DEFI_MATERIAU` [U4.43.01] and `AFFE_MATERIAU` [U4.43.03]).***

***The concept produced by this operator is of `evol_elas` type containing one or more fields of displacements at the various moments of calculation.***

***In the case of the static mechanical analysis, one assigns the sequence number 0 (moment 0) to the field solution.***

***Product a structure of data of the `evol_elas` type.***

***When a calculation of sensitivity of the result compared to a parameter is required, there is production of as many structures of data of the `evol_elas` type than of definite parameters of sensitivity.***

### **3 Operands**

**3.1 Operands**  
**MODEL/CHAM\_MATER/CARA\_ELEM**

**One provides the arguments allowing to calculate the matrix of rigidity (and the second member):**

**MODEL = Mo,**

**Name of the model whose elements are the subject of mechanical calculation.**

**CHAM\_MATER = chmat,**

**Name of the material field.**

**CARA\_ELEM**  
**= carac,**

**Name of the characteristics of the structural elements (beam, hull, discrete,...) if they are used in the model.**

## **3.2 Word**

**key**

**EXCIT and operands INST/LIST\_INST**

*One defines here the boundary conditions and the loadings.*

**EXCIT**

=

*This key word factor makes it possible to define several concepts of the type charges, one by occurrence;*

*solution is calculated by superimposing the effects of the various loads applied.*

### **3.2.1 Operands**

**CHARGE/FONC\_MULT**

**CHARGE = tank,**

*Name of a concept of the char\_meca type produces by AFFE\_CHAR\_MECA or AFFE\_CHAR\_MECA\_F [U4.44.01] starting from the model Mo. Only one occurrence must make reference to the temperature (load with TEMP\_CALCULEE).*

*One can also give the name of a “kinematic load” (standard char\_cine\_meca) result of operators AFFE\_CHAR\_CINE and AFFE\_CHAR\_CINE\_F [U4.44.03].*

**FONC\_MULT = fmult,**

*Name of a concept of the function type (or formulates) which makes it possible to define for each moment of calculation a multiplying coefficient applied to the load tank.*

*For a thermal loading of origin (dilation) defined by TEMP\_CALCULEE in order AFFE\_CHAR\_MECA [U4.44.01] the field of temperature is not multiplied by fmult.*

*fmult is a function of time: by defect it is a constant function which is worth 1.*

### **3.2.2 Operands**

**INST/LIST\_INST**

**/INST = tps,**

*Key word used to carry out calculation at only one moment tps with the temperature correspondent at this moment.*

**Instruction manual**

**U4.5- booklet: Methods of resolution**  
**HT-62/06/004/A**

**Author (S):**

**J. Key PELLET**

**:**

**U4.51.01-II Page**

**: 4/6**

**/LIST\_INST = litps,**

**INST\_FIN = tf,**

**The list litps produced by DEFI\_LIST\_REEL [U4.34.01] defines the moments for which one ask for the calculation of a thermomechanical evolution.**

**Key word INST\_FIN makes it possible to calculate only the moments former or equal to tf.**

**This key word (INST\_FIN) compound with the key word “reuse” (order réentrante) allows to split a long thermomechanical transient.**

**One will make for example:**

**resu = MECA\_STATIQUE (...**

**LIST\_INST = linst, INST\_FIN = 10. ,...)**

**MECA\_STATIQUE (reuse = resu, LIST\_INST = linst, INST\_FIN = 20. ,...)**

**MECA\_STATIQUE (reuse = resu, LIST\_INST = linst, INST\_FIN = 30. ,...)**

**3.3**

**Key word factor SOLVEUR**

**See [U4.50.01].**

### **3.4 Word**

*key*

**SENSITIVITY**

*Activate the calculation of derived from the field of displacement compared to a parameter of the problem.*

*See [U4.50.02].*

### **3.5 Operand**

**OPTION**

**OPTION =/“WITHOUT”**

**/“SIEF\_ELGA\_DEPL”**

*By defect order MECA\_STATIQUE calculates the constraints at the points of Gauss (or efforts generalized for the elements of structure).*

*The other options of postprocessing will be calculated a posteriori by order CALC\_ELEM [U4.81.01].*

*If the user indicates OPTION = “WITHOUT”, these constraints will not be calculated and the structure*

*data produced will be less bulky.*

### **3.6 Operand**

**INFORMATION**

**INFORMATION = 1,**

*Print the principal characteristics of the linear systems to solve: a number of unknown factors, cut matrix.*

### **3.7 Operand**

**TITRATE**

**TITRATE = titr,**

*Titrate that one wants to give to the result [U4.03.01].*

***31/01/06***

***Author (S):***

***J. Key PELLETT***

***:***

***U4.51.01-II Page***

***: 5/6***

***4***

***Examples of calculations***

***4.1***

***Static calculation with superposition of 2 loading cases***

***mest1 = MECA\_STATIQUE (***

***MODEL = Mo, CHAM\_MATER = chmat,***

***CARA\_ELEM***

***=***

***carac,***

***EXCIT = (\_F (LOAD = ch1, FONC\_MULT = COS),***

***\_F (***  
***CHARGE***

***:***

***ch2***

***),), )***

***4.2***

***Thermoelastic calculation at various moments***

***ch\_temp = AFFE\_CHAR\_MECA (***  
***... TEMP\_CALCULEE = evoth... ) );***

***mest2 = MECA\_STATIQUE (***

***MODEL = Mo, CHAM\_MATER = chmat,***

```
EXCIT  
=  
(_F (  
CHARGE  
=  
ch_temp  
),
```

```
_F (LOAD = bloq),),  
LIST_INST  
=  
litps  
)
```

### 4.3 *Sensitivity to an imposed displacement*

```
psx= DEFI_PARA_SENSI (VALE=7.0)  
psy= DEFI_PARA_SENSI (VALE=3.0)
```

```
ch=AFFE_CHAR_MECA_F (MODELE=mo,  
FACE_IMPO=_F (GROUP_MA=' BORD_SUP', DX=psx, DY=psy))
```

```
mest3 = MECA_STATIQUE (  
  
MODEL = Mo, CHAM_MATER = chmat,  
EXCIT  
=  
_F (  
CHARGE  
=  
CH  
)
```

```
SENSIBILITE= (psx, psychiatrist),)
```

*This calculation will produce the structure of data mest3 of the evol\_elas type, containing the field of displacement penny sle name "DEPL". It will produce two other structures of data of the type evol\_elas. The first will contain under the name of field "DEPL", the field of derived from displacement compared to the parameter psx. The second will contain the derivative compared to psychological parameter.*

*The name of these 2 structures is created automatically by the code and remains unknown to the user. The access to their contents (impression, test, post\_releve,...) is done by calling upon the order corresponding with the name of the principal structure, mest3, and the name of the significant parameter concerned (psx or psychiatrist).*

## **5 Remark**

*For certain studies in linear elasticity for which characteristics of rigidity of structure are independent of the thermal history and the boundary conditions kinematics independent of the other loads, one can determine the deformations for several cases of loading by using MACRO\_ELAS\_MULT [U4.51.02].*

***Macro order MACRO\_ELAS\_MULT***

***1 Goal***

*To calculate linear static answers for various loading cases or modes of Fourier.*

*It is supposed that the conditions kinematics (blockings of the structure) and the characteristics of materials are invariant for all the loading cases, which makes it possible to have the same matrix of rigidity.*

*The structure of data produced is of mult\_elas type for the multicas of load or fourier\_elas for calculations of Fourier.*

**3 Operands**

**3.1 Operands**

***MODEL/CHAM\_MATER/CARA\_ELEM***

***One provides the arguments allowing to calculate the matrix of rigidity (and second members).***

***MODEL***

***= Mo,***

***Name of the model whose elements are the subject of mechanical calculation.***

***CHAM\_MATER = chmat,***

***Name of the material field.***

***CARA\_ELEM***

***= carac,***

***Name of the characteristics of the structural elements (beam, hull, discrete,...) if they are used in the model.***

**3.2 Operand**

***NUME\_DDL***

***NUME\_DDL = naked,***

***Key word used to name classification for a later use or to use one***

*existing classification. If no name is provided, a classification is created temporarily for each call to MACRO\_ELAS\_MULT.*

### **3.3 Operands**

**CHAR\_MECA\_GLOBAL/CHAR\_CINE\_GLOBAL/  
LIAISON\_DISCRET**

**/CHAR\_MECA\_GLOBAL**  
**= lchmg,**

*Key word defining the boundary conditions mechanical of blocking of the structure. These conditions are the same ones for all the loading cases. They are defined by AFFE\_CHAR\_MECA or AFFE\_CHAR\_MECA\_F [U4.44.01].*

**/**  
**CHAR\_CINE\_GLOBAL**  
**= lchcg,**

*Key word defining the conditions kinematics of blocking (eliminated) of the structure.*

*These conditions are the same ones for all the loading cases. They are defined by AFFE\_CHAR\_CINE or AFFE\_CHAR\_CINE\_F [U4.44.03].*

**/LIAISON\_DISCRET = "YES",**

*This key word is simply used to say that there are not mechanical conditions or kinematics of blocking of the structure.*

### **3.4 Word**

**key**

**CAS\_CHARGE**

*Key word factor allowing to define a loading case.*

*For each occurrence of the key word factor, one builds a second member (except if one uses VECT\_ASSE (in which case the second member is already assembled)) and one résoud the linear system.*

#### **3.4.1 Operand**

**NOM\_CAS**

**NOM\_CAS = moncas,**

*Character string, is used as variable of access to the structure of data result.*

**Note:**

*Each case is named by the user and the concept of sequence number does not exist.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

*:*

*U4.51.02-E Page*

*: 4/6*

**3.4.2 Operands**

**MODE\_FOURIER/TYPE\_MODE**

*MODE\_FOURIER*

*= mode,*

*Positive or null entirety indicating the harmonic of FOURIER on whom one calculates the matrix elementary of rigidity and the elementary vector.*

*TYPE\_MODE*

*= standard,*

*The type of the harmonic will be symmetrical (“SYME”), or antisymmetric (“ANTI”) or symmetrical and antisymmetric (“ALL”) (cf the note of use Fourier [U2.01.07]).*

**3.4.3 Operands**

**CHAR\_MECA/CHAR\_CINE/VECT\_ASSE**

*CHAR\_MECA*

*= lcharm,*

List concepts of the *char\_meca* type produces by *AFFE\_CHAR\_MECA* [U4.44.01] or *AFFE\_CHAR\_MECA\_F* [U4.44.01] starting from the model *Mo*.

*CHAR\_CINE*  
= *lcharc*,

List concepts of the *char\_cine\_meca* type produces by *AFFE\_CHAR\_CINE* [U4.44.03] from model *Mo*.

*VECT\_ASSE*  
= *chdep*,

Concept of the *cham\_no\_depl\_r* type representing the second member of the linear system with to solve.

### 3.4.4 Operands

#### ***OPTION/NUME\_COUCHE/NIVE\_COUCHE***

One asks, if it is wished, of the options of calculation of postprocessing starting from displacements. One can not request these options from this stage of the study to analyze the solution in displacement ; then, in a later work, to supplement the concept produced by using order *CALC\_ELEM* [U4.81.01] or *CALC\_NO* [U4.81.02] orders it.

*OPTION*  
= *option*,

The significance of the options is given in orders *CALC\_ELEM* [U4.81.01] and *CALC\_NO* [U4.81.02].

When the model contains elements of hull, one will be able to specify, if necessary, for calculation of certain options:

*NUME\_COUCHE* = *nume*,

In the case of a multi-layer material, value ranging between 1 and number it layers, necessary to specify the layer where one wishes to carry out elementary calculation. By convention layer 1 is the sub-base. By defect the number of layer is 1 for a full-course element of hull.

*NIVE\_COUCHE* = *nive*,

For the *nume* layer defined by *NUME\_COUCHE*, allows to specify the level in the thickness where one wants to carry out elementary calculation:

*Lower ordered “INF” of the layer (lower skin),  
Higher ordered “SUP” of the layer (higher skin),  
Average ordered “MOY” of the layer (average layer).

**Operator STAT\_NON\_LINE**

**1 Goal**

**To calculate the mechanical evolution or coupled thermo-hydro-mechanics, into quasi-static, of a**

**structure  
into nonlinear.**

**Nonthe linearity is related either to the behavior of material (for example plastic), or with the geometry (for example in great displacements). To have details on the method of resolution employed, one will refer to the reference material [R5.03.01].**

**The evolution can be studied in several successive work (réentrant concept), that is to say in continuation (it last calculated moment is the initial moment of following calculation), that is to say in recovery on the basis of one moment former.**

**If time necessary to carry out calculation is not sufficient, the program stops, but them already calculated results are safeguarded if a data base were defined in the profile of study of the user. Product a structure of data of the evol\_noli type.**

### ***3 Operands***

#### ***3.1 Operands***

***MODEL/CHAM\_MATER/CARA\_ELEM***

***MODEL = Mo***

***CHAM\_MATER = chmat***

***CARA\_ELEM = carac***

***These key words make it possible to inform:***

- the name of the model (Mo) whose elements are the subject of mechanical calculation,***
- the name of the material field (chmat) affected on the grid. Attention, all meshes model must be associated a material (if not fatal error with message little***

*clarify),*

*· the name of the characteristics (carac) of the elements of hull, beam, pipe, bars, cable, and discrete elements affected on the model Mo. Obviously, this key word is optional: if the model does not contain such elements, it is not useful; on the other hand, if the model contains such elements, it is obligatory.*

### **3.2 Word**

*key*

**EXCIT**

**EXCIT:**

*This key word factor makes it possible to describe with each occurrence a load (requests and conditions with the limits), and possibly a multiplying coefficient and/or a type of load.*

#### **3.2.1 Operands**

**CHARGE**

**CHARGE: chi**

*CH is the mechanical loading (possibly comprising the evolution of a field of I temperature) specified with the ième occurrence of EXCIT.*

*One and only one load can comprise the evolution of a field of temperature, which will have previously be defined thanks to key word TEMP\_CALCULEE of the order AFFE\_CHAR\_MECA.*

**Caution:**

*In a thermomechanical calculation, if the initial temperature is different from the temperature of reference (given in operator AFFE\_MATERIAU), the field of deformation associated with the initial moment can be incompatible and thus lead to a state of stresses and variables interns associated not no one. If one uses a relation of behavior incremental (key word factor COMP\_INCR) and if one explicitly does not define a state of stresses and variables interns initial (associate with a field of initial temperature different from the temperature from reference), the internal variable and stress field calculated to the first increment account will hold that only variation in temperature enters the initial moment and the first moment, and not of the possible constraints of compatibility associated with the initial temperature. To take this initial state hopes some, it should be given explicitly, for example thanks to key words SIGM, DEPL, VARI and VARI\_NON\_LOCAL in ETAT\_INIT. To avoid such situations which can lead to miscalculations, it is worth to better begin a calculation while considering than it is necessary to start from a virgin state.*

**Caution:**

*If one carries out a calculation into axisymmetric and that one imposes nodal forces, these efforts must be divided by  $2*\text{Pi}$  (one works on a sector of 1 radian) compared to real loadings. In the same way, if one wishes to calculate the resultant of the efforts, the result is to multiply by  $2*\text{Pi}$  to have the total resultant on the complete structure. In the same way in plane constraints or in plane deformation, one works on a thickness unit: efforts (on the thickness) applied must be divided by the thickness, the real efforts are obtained by multiplying by the thickness the efforts “of calculation”.*

**Caution:**

*The loadings resulting from AFFE\_CHAR\_CINE are not usable with STAT\_NON\_LINE.*

### **3.2.2 Operand**

**FONC\_MULT**

**FONC\_MULT: fi**

*F is the multiplying function of the time of the loading specified with the ième occurrence of I*

*EXCIT.*

*The loading and the boundary conditions for N occurrences of the key word factor EXCIT are:*

*N*

*CH =*

*F CH**I**I**i=1**For the conditions of Dirichlet, of course, only the specified value is multiplied by F.**I**By defect:  $f_i = 1$ .***Note:***The field of temperature is not multiplied by F.**I*

### **3.2.3 Operand**

#### **TYPE\_CHARGE**

**TYPE\_CHARGE: *tchi****By defect, tchi is worth “FIXE\_CSTE”: that corresponds to a loading applied to initial geometry and not controlled. It can however be a function, and, in particular, to depend on time.**If tchi is worth “FIXE\_PILO”, the loading is always fixed (independent of the geometry) but will be controlled thanks to the key word PILOTING [§3.11]. The loads controllable must result AFPE\_CHAR\_MECA or AFPE\_CHAR\_MECA\_F and not to be affected key word FONC\_MULT. One cannot control the loadings of gravity, the centrifugal force, the forces of Laplace, thermal loadings or of initial or anelastic deformations, and conditions of connection.**If tch is worth**I**“SUIV”, the loading is known as “follower”, i.e. it depends on the value on unknown factors: for example, pressure, being a loading applying in the normal direction with a structure, depends on the geometry brought up to date of this one, and thus on displacements. One**following loading is revalued with each iteration of the algorithm of resolution. A loading fix is revalued only at each new moment, and only if chi depends on time (defined in AFPE\_CHAR\_MECA\_F and parameterized by the moment).**Currently the loadings which can be qualified “SUIV” are the loading of gravity for the element of CABLE\_POULIE, the pressure for modelings 3D, 3D\_SI, D\_PLAN, D\_PLAN\_SI, AXIS, AXIS\_SI, C\_PLAN, C\_PLAN\_SI and for all modelings THM (3D\_HHM, 3D\_HM, 3D\_JOINT\_CT, 3D\_THH, 3D\_THHM, 3D\_THM, AXIS\_HHM, AXIS\_HM, AXIS\_THH, AXIS\_THHM, AXIS\_THM, D\_PLAN\_HHM, D\_PLAN\_HM, D\_PLAN\_THH,*

*D\_PLAN\_THHM, D\_PLAN\_THM) and the centrifugal force in great displacements (key word ROTATION in AFFE\_CHAR\_MECA).*

*If tchi is worth "DIDI then" the conditions of Dirichlet (imposed displacements, conditions linear) will apply to the increment of displacement as from the moment given under ETAT\_INIT/NUME\_DIDI (by defect the moment of resumption of calculation) and not on displacement total. For example for an imposed displacement (key word DDL\_IMPO of AFFE\_CHAR\_MECA) condition will be form:  $U - U = D$*

*0  
where u0 is the displacement defined by NUME\_DIDI and  
not:  $U = D$ .*

### **3.3 Key word SOUS\_STRUC**

*For more precision concerning the use of substructures (elastic linear) in one nonlinear structure, one will refer to documentation [U2.07.02]*

### **SOUS\_STRUC**

*This key word factor makes it possible to specify which are the loadings to be used for substructures. In its absence, the loadings on under structures are null.*

*These loadings are added to the loadings “finite elements” which can be applied to remain model.*

***CAS\_CHARGE = nocas***

*nocas is the name of the loading case to be used. See operator MACR\_ELEM\_STAT [U4.62.01].*

***/ALL = “YES”***

*This key word makes it possible to affect the loading nocas to all under structures of model.*

***/MESH = l\_mail***

*This key word factor makes it possible to assign the loading nocas only to some substructures.*

### ***3.4 Key words***

***COMP\_INCR and COMP\_ELAS***

*The syntax of these key words common to several orders is described in the document [U4.51.11].*

### ***3.5 Word***

***key***

***VARI\_COMM***

***VARI\_COMM***

***:***

*Variables of orders which control the laws of behavior (as well as temperature).*

#### ***3.5.1 Operand***

***IRRA & CORROSION***

***/IRRA***

***:***

***irr***

*Exposure fields.*

**/CORROSION**

**: corro**

*Fields of corrosion.*

**3.6 Word**

**key**

**ETAT\_INIT**

**ETAT\_INIT:**

*Initial State of reference selected. By defect, all the fields are identically null. This initial state can be defined either by specifying each field of the initial state, or in extraction since one concept of the preexistent evol\_noli type.*

*The data of an initial state does not have a direction (and is not thus taken into account) only for the part of field treated in incremental behavior (COMP\_INCR); if the behavior is elastic (COMP\_ELAS) that does not have any incidence.*

***If one wants to take into account an initial state in elasticity, it is key word ELAS located under COMP\_INCR which should be used.***

13/34

**Note:**

*If the user specified that the concept result is réentrant (by the reserved word reuse), key word ETAT\_INIT is obligatory.*

**3.6.1 Operands****SIGM/VARI/DEPL/VARI\_NON\_LOCAL**// **SIGM**

=

**sig**/ **VARI**= **vain**/ **DEPL**= **depl**/ **VARI\_NON\_LOCAL = vanolo**

*Respectively, stress fields at the points of Gauss, variables intern at the points of Gauss, of displacements to the nodes and nonlocal variables to the nodes (for models not buildings) taken in an initial state. If one of these fields is not specified, it is taken null by defect. They*

*can for example be resulting from order CREA\_CHAMP, or be read in one file with format I-DEAS by order LIRE\_RESU (attention format MED only reads fields with the nodes).*

**3.6.2 Operands****EVOL\_NOLI**

/

**EVOL\_NOLI**

:

**evol**

*Name of the concept of the evol\_noli type from where will be extracted the initial state.*

### 3.6.3 Operand

**NUME\_ORDRE/INST/NUME\_DIDI**

**/NUME\_ORDRE**

= *nuini*

/

**INST**

=

***instini***

*Extraction of the initial mechanical state in evol starting from the number of filing NUME\_ORDRE or of the moment of filing INST to carry out the continuation of calculation. If NUME\_ORDRE or INST are not filled, the last filed number is taken existing in evol.*

**NUME\_DIDI: nudidi**

*In the case of loadings of the differential type DIRICHLET (“DIDI”), one gives under NUME\_DIDI the number of filing of the mechanical state (displacement) which is used as reference for the application of these boundary conditions (cf [§3.2.2]). By defect one takes the definite mechanical state under NUME\_ORDRE or INST.*

### 3.6.4 Operand

**INST\_ETAT\_INIT**

**INST\_ETAT\_INIT: istetaini**

*One can associate a value of moment istetaini in this initial state.*

*By defect:*

- *when the initial state is defined by the data of the fields, it does not have there an associated moment.*
- *when the state is given by a concept evol\_noli, it acts of the moment in the precedent calculation (istetaini = instini).*

### **3.7 Word**

*key*

**INCREMENT**

**INCREMENT:**

*Defines the intervals of time taken in the incremental method.*

*The moments thus defined have physical direction only for relations of behavior where time intervenes explicitly (viscoelastic or viscoplastic for example). In the others cases, they allow only indicer the increments of load and to parameterize the evolution of one possible field of temperature.*

#### **3.7.1 Operands**

**LIST\_INST/EVOLUTION**

**LIST\_INST: *litps***

*The moments of calculation are those defined in the concept *litps* by operator *DEFI\_LIST\_REEL* [U4.34.01].*

**EVOLUTION**

**: /“CHRONOLOGICAL”**

**[DEFECT]**

/

**“RETROGRESSES”**

/

**“WITHOUT”**

The “**CHRONOLOGICAL**” key word makes it possible to check if the list of moments given by the user is

strictly increasing (so not an error message is transmitted).

The “**RETROGRADE**” key word makes it possible to reverse the list of moments given by the user and of

to check that after this operation, it is well strictly decreasing.

There is no checking when one specifies an evolution “**WITHOUT**”.

**3.7.2 Operands**

**NUME\_INST\_INIT/INST\_INIT/NUME\_INST\_FIN/INST\_FIN**

/

**NUME\_INST\_INIT = nuini**

/

**INST\_INIT**

**= instini**

The initial moment of the calculation (which thus (Re) is not calculated) is indicated either by its value (**INST\_INIT**), that is to say by its sequence number in the list of moments litps (**NUME\_INST\_INIT**).

To be able to reach by value, it is necessary that the list is ordered (**EVOLUTION: “CHRONOLOGICAL”** or “**RETROGRESSES**”).

In the absence of key words **INST\_INIT** or **NUME\_INST\_INIT**, the defect is calculated following manner:

- if an initial state is specified (operand **ETAT\_INIT**) and if it defines one moment corresponding (by **EVOL\_NOLI** or **INST\_ETAT\_INIT**) then the initial moment is that defined by the initial state,
- if there is no initial state (operand **ETAT\_INIT**) or that it does not define a moment corresponding (the fields are given in **ETAT\_INIT** without specifying **INST\_ETAT\_INIT**), then one takes the first moment of the list of moments litps (**NUME\_INST\_INIT: 0**), or the last when the evolution is retrograde.
- In the event of filing (see keyword **FILING**), the initial moment in continuation is its last step filed and not that defined in **INST\_INIT**.

/  
**NUME\_INST\_FIN**

=  
**nufin**

/  
**INST\_FIN**

=  
**instfin**

*The final moment (last calculated step) is indicated same manner that the initial moment (either NUME\_INST\_FIN, is INST\_FIN), except that it is not possible to refer to the moment initial state.*

**Caution:** with an evolution RETROGRAGE, INST\_INIT > INST\_FIN.

### **3.7.3 Operand PRECISION**

**PRECISION:** *prec* cf [U4.71.00]

### **3.7.4 Operand**

**SUBD\_PAS/SUBD\_PAS\_MINI/COEF\_SUBD\_PAS\_1**

**SUBD\_PAS**

=  
**subpas**  
**SUBD\_PAS\_MINI = submini**  
**COEF\_SUBD\_PAS\_1**

**= coefsub**

*Allows to carry out an automatic recutting of the step of time when the algorithm of Newton do not converge.*

*The step of time is redécoupé in subpas under step. By defect there is no recutting (subd\_pas: 1). The automatic subdivision stops when the new steps created are more small that SUBD\_PAS\_MINI. The new steps created are of identical size, except the first who is equal to this size multiplied by COEF\_SUBD\_PAS\_1 (by defect 1). This allows best to take into account the problems of discharge of the structure (change of tangent matrix) without using the elastic matrix (PREDICTION: "ELASTIC" or STAMPS: "ELASTIC" under the operand NEWTON).*

*When a step of time was redécoupé several times (let us call N the number of times where one has proceeded to a subdivision of the same step), the following step is automatically subdivided (n-1) time, this to avoid, in the event of convergence difficult to try a step of too important time.*

**Notice concerning the key word CUTS OUT under SOLVEUR:**

*During elastoplastic calculation of buckling, it can happen that the tangent matrix of the system that is to say singular during iterations of Newton. By redécoupant the step of time, one can to pass these hard points. Under operand SOLVEUR, the key word CUTS OUT under STOP\_SINGULIER is used to manage these hard points. It is then necessary to inform the words keys relating to recutting so that the method CUTTING is activated.*

#### ***vale***

*These operands have interest only when a thermomechanical calculation is carried out. Allows to create if need be a new list of mechanical step of time so that, between each increment of time, the increment of temperature is lower than a value given by the user and indicated by key word VALE.*

*The creation of this new list is done in the following way:*

- Liste of moments initial in mechanics:  $T_i$*
- Thermal Liste of moments:*
- Nouvelle final list of moments mechanical to create if need be:  $T_f$*
- One inserts between each interval of the basic list mechanical  $T_i$ , the thermal moments include in this interval. One then recovers for each interval a list of moments =*  
*[0, 1, 2, NR]*

*· Construction of the list final  $T_f$*

*- Initialization:  $F = 0$*

*- 1st Test:*

*If  $T(J) - T(F) > \text{value}$  with  $T(T)$  the temperature at time  $T$  and  $F$  the last moment inserted in the new  $T_f$  list, then one keeps in the new list  $T_f$ , the moment*

*$j-1$*

*- 2nd Test:*

*If  $T(J) - T(j-1) > \text{value}$  then one redécoupe uniformly this interval in way to satisfy the condition on the increment of temperature.*

***Example:*** *IF  $T() = [T(1) = 20^\circ\text{C}, T(2) = 30^\circ\text{C}, T(3) = 55^\circ\text{C}, T(4) = 65^\circ\text{C}]$  with  $VALE = 15^\circ\text{C}$*

*Initialization:  $F = 1$*

*Interval 1:*

*1st Test = 2nd Test:  $T(2) - T(1) = 10^{\circ}\text{C} < 15$  thus one  $T_f = [1]$*

*Interval 2:*

*1st Test:  $T(3) - T(F) = 35^{\circ}\text{C} > 15$  thus one has  $T_f = [1, 2]$  and  $F = 2$*

*2nd Test:  $T(3) - T(2) = 25^{\circ}\text{C} > 15$  thus one  $T_f = [1, 2, T3]$  such as  $T(T3) = 42.5^{\circ}\text{C}, 3]$  and  $F = 3$*

*Interval 3:*

*1st Test = 2nd Test:  $T(4) - T(3) = 10^{\circ}\text{C} < 15^{\circ}\text{C}$*

*from where the following final list:*

*$T_f = [1, 2, T3]$  such as  $T(T3) = 42.5^{\circ}\text{C}, 3, 4]$*

Titrate:

Operator **STAT\_NON\_LINE**

Date

:

31/01/06

Author (S):

**Mr. Key ABBAS**

:

U4.51.03-H1 Page:

18/34

*When the key word misses, it is the tangent matrix of speed (option RIGI\_MECA\_TANG in the file .mess) which is used if one chose for the method of NEWTON one STAMP: "TANGENT", and it is the elastic matrix (option RIGI\_MECA in the file .mess) who is used if MATRIX were chosen: "ELASTIC".*

***/"TANGENT"***

*One uses the tangent matrix of the problem of speed (option RIGI\_MECA\_TANG in the file .mess).*

***/"ELASTIC"***

*The elastic matrix is used (option RIGI\_MECA in the file .mess).*

***/"EXTRAPOL"***

*One calculates the estimate of the increment of displacement starting from the total increment obtained like solution with the step of previous time (balanced by the report/ratio of the steps of time). One projects this estimate on the whole of the fields kinematically acceptable (i.e satisfying them boundary conditions of DIRICHLET) according to the standard given by the elastic matrix, which must thus to be calculated. This functionality is interesting in the case of the use of diagrams of explicit integration local of type RUNGE-KUTTA which does not provide a tangent matrix: in this case the method of NEWTON uses an elastic matrix, but the iteration count necessary can be high. The use of extrapolation can improve the performances.*

***/"DEPL\_CALCULE"***

*Allows to propose like displacement for the prediction with each step of time, it displacement given by a mechanical history specified under key word EVOL\_NOLI ([§3.8.3]).*

**Utility:**

*· let us suppose that one carries out the first calculation with a coarse grid. One wishes to carry it out even calculation but on a finer grid. One can suppose that the solution in displacement for this second calculation is not distant from that of the first calculation and thus only one good prediction of displacement for this second calculation is the projection of displacements of calculation*

*l* on the nodes of the new grid (the projection of displacements on the new grid must be realized beforehand with operator *PROJ\_CHAMP* [U4.72.05]). This key word allows to carry out this mode of prediction.

· that makes it possible to reduce the place memory and to preserve these results for a continuation later. For a large calculation, one can store only displacements with all their moments with formats *IDEAS* or *MED* in *IMPR\_RESU*. If one wants to recompute the constraints and internal variables, one makes a *LIRE\_RESU* with the adequate format then one uses *DEPL\_CALCULE* with *ITER\_GLOB\_MAXI: 0* (only one iteration is carried out) and *STOP: NOT* (there is not convergence, one does not check balance). It is however necessary for reasons of syntax to give a loading (to avoid the loadings dirichlet which impose one linear resolution) as well as a criterion of convergence, even if this information is not takings into account.

### **3.8.2 Operand STAMP**

**STAMP =**

**/**  
**“TANGENT”**

**REAC\_INCR**

**=**  
**/**  
**1**  
**[DEFECT]**

**/MF**

**REAC\_ITER**

**=**  
**/**  
**0**  
**[DEFECT]**

*/it*

*The matrix used for the total iterations of the method is the tangent matrix [R5.03.01] who is revalued all MF increments of time (MF positive or null) and all the it iterations of NEWTON for an increment of time given (precisely to the iterations of number it, 2it, 3it...). Thus with the first iteration of NEWTON, one reassembles the tangent matrix only if it I is worth: if not one keeps the matrix used in the phase of prediction. By convention if it is worth 0 the matrix is not revalued during all the step of time.*

**PAS\_MINI\_ELAS**

=

/

**0.**

**[DEFECT]**

/

***pasmini [R]***

***REAC\_ITER\_ELAS =/  
0  
[DEFECT]  
/  
it  
[I]***

*Allows to pass from the tangent matrix to the matrix of discharge (i.e by considering that not linearities do not evolve/move) when the step of time is or becomes (by recutting) lower than pasmini. This matrix of discharge is the elastic matrix for the models of behavior of plastic type; for the models of damage it is identified with the secant matrix. As convergence with the elastic matrix is slower than that with the matrix tangent, key word ITER\_GLOB\_ELAS under the key word factor CONVERGENCE makes it possible to define an iteration count maximum specific to the use of the matrix elastic and different from that associated the use of the tangent matrix.*

*One can define a frequency of reactualization of the matrix of discharge with the key word REAC\_ITER\_ELAS (similar of REAC\_ITER). If the matrix of discharge does not depend on the state of deformation, to take REAC\_ITER\_ELAS = 0 (since it will be the same one during iterations).*

***Utility:***

*This option can be useful when the automatic recutting of the step of time (cf [§ 3.7.4]) converge a calculation is not enough to make. For example, in the case of lenitive laws, the matrix tangent can become singular and it is thus to better use the elastic matrix to converge.*

***“ELASTIC”***

*The matrix used corresponds to the elastic design: it is evaluated only once at the moment initial, at the beginning of algorithm.*

*This “elastic” matrix is calculated by using the YOUNG modulus given under the key word ELAS of operator DEFI\_MATERIAU, and not the slope at the origin of the traction diagram given under the key word TRACTION (and which are useful, it, in the expression of the relation of behavior).*

### ***3.8.3 Operand EVOL\_NOLI***

TYPE = "DDL\_IMPO",**

**NODE = NO1,**

**NOM\_CMP**

=  
**“DX”**,  
**COEF\_MULT**

=  
 5.))

*In the fichier.resu, the value of will be at every moment posted calculation. To know charge limit, it is enough to make  $P_{\text{limite}} = *P_x$ . (Here  $P_x$  is worth 1 thus one has the limiting load directly).*

*If one imposes on the structure a pressure  $P$  close to the limiting load without using piloting, it calculation will not converge if one is close to the limiting load.*

### **3.11.6 Operand $ETA\_PILO\_R\_MAX/ETA\_PILO\_R\_MIN$**

**$ETA\_PILO\_R\_MAX = etarmax$ ,**  
**[R]**

**$ETA\_PILO\_R\_MIN$**

=  
 **$etarmin$ ,**  
**[R]**

*These two key words make it possible to specify the interval of awaited values of piloting. principle of operation is as follows: with each iteration of Newton, if values are found of piloting in the interval  $[etar\ min, etar\ max]$ , all values of piloting apart from this interval are not considered. On the other hand, if no value of piloting is found in this interval, all the values of piloting are preserved.*

*If one does not specify values, it is - for  $etarmin$  and + for  $etarmax$ .*

*A possible use of this interval is as follows. one wishes for example, to control a pressure some share on the structure and one expects to keep this positive pressure. By fixing  $etarmin$  at 0, that make it possible to preserve only the positive values of piloting, if at least one is found positive value of piloting at the time of the resolution of piloting.*

### **3.11.7 Operand $ETA\_PILO\_MAX/ETA\_PILO\_MIN$**

**$ETA\_PILO\_MAX:$**   
 **$etamax$**

*Stop of calculation when the parameter of piloting reaches the value given  $etamax$ .*

## ***ETA\_PILO\_MIN:***

***etamin***

***Allows to stop calculation when parameter ETA\_PILOTAGE reaches this minimal value etamin (for lenitive models, makes it possible to stop calculation when the structure is sufficient softened).***

### ***Caution:***

***With law ENDO\_ISOT\_BETON, these two words key are obligatory.***

***This key word makes it possible to start calculation, at the end of each increment of time, of a criterion of stability.***

***This criterion is useful to detect, during the loading, the point from which one loses stability (by buckling for example).***

*This criterion is calculated in the following way: at the end of a step of time, in small disturbances, one solves  $\det (T$*

*K -*

*G*

*K) = 0.  $KT$  is the coherent tangent matrix at this moment.  $Kg$  is*

*stamp geometrical rigidity, calculated starting from the stress field at this moment.*

*In practice, the loading is unstable if  $< 1$  ( $-1 < < 0$  make some). The values are calculated clean by the method of Sorensen (Cd `MODE_ITER_SIMULT`). This can be rather expensive for the problems of big size.*

*Key word `CHAR_CRIT` makes it possible to save time by making only one test of Sturm in provided frequency band. If at least a frequency is found, then one calculates really them values of the critical loads in this interval.*

*For great displacements and great deformations `GREEN (_GR)` or `SIMO_MIEHE`, one solves  $\det (K T - Id) = 0$  bus  $KT$  contains  $kg$  then (and possibly  $Kp$ ).*

*The criterion is then a criterion of instability: when sign (thus passes by 0) it changes loading is unstable.*

*Key word `NB_FREQ` (3 per defect) indicates the number of critical loads to calculate. In fact only the first is enough but there can be multiple modes*

*One stores the clean mode the corresponding to smallest critical load (in absolute value) in the S.D. `RESULT`, under name `MODE_FLAMB`. This clean mode can be extracted and visualized (like a field of displacements or a traditional clean mode). It is standardized to 1 on more large component of displacement.*

/  
“CTCC\_GEOM”,

*Type of the column to be posted (each value corresponds to a posted column):*

*ITER\_NEWT: number of the iteration of Newton in progress. The column is marked by “X” as long as it convergence there on all the criteria did not have.*

*INCR\_TPS: moment of current calculation.*

*RESI\_RELA and RELA\_NOEU: value of RESI\_GLOB\_RELA and posting of the node where it is maximum.*

*column is marked by X as long as the residue is larger than that specified by the user (operand RESI\_GLOB\_RELA).*

*RESI\_MAXI and MAXI\_NOEU: value of RESI\_GLOB\_MAXI and posting of the node where it is maximum.*

*column is marked by X as long as the residue is larger than that specified by the user (operand RESI\_GLOB\_MAXI).*

*RESI\_REFE and REFE\_NOEU: value of RESI\_REFE\_RELA and posting of the node where it is maximum.*

*column is marked by X as long as the residue is larger than that specified by the user (operand RESI\_REFE\_RELA).*

*RELI\_ITER and RELI\_COEF: iteration count and linear coefficient of research.*

*PILO\_PARA: value of the parameter of piloting.*

*LAGR\_ECAR,*

*LAGR\_INCR and LAGR\_ITER: parameters of Lagrangian increased (see LAGR\_NON\_LOCAL)*

*MATR\_ASSE: option of assembly for the matrix (elastic, tangent, secant)/*

*ITER\_DEBO: indicate an iteration of Borst for the plane constraints or the behaviors unidimensional (see COMP\_INC)*

*CTCD\_ITER: iteration count intern contact/friction, methods discrete. The column is marked by X as long as the contact did not converge on the geometry.*

*CTCD\_INFO: information on the state of contact for the discrete methods:*

- ALGO: resolution of the problem of contact (iterations intern)*

- ALGO/REAC\_GEOM: resolution of the problem of contact (internal iterations) and updated of geometry for reactualization*

- INIT\_GEOM/ALGO: initialization of the geometry for the contact and resolution of the problem of contact.*

- ATT\_PT\_FIXE: do not make an attempt fixes for the contact discrete methods*

*CTCD\_GEOM: value of maximum displacement for the geometrical reactualization of the contact, discrete methods.*

*CTCD\_NOEU: node where the value of displacement is maximum during the geometrical reactualization*

*contact, discrete methods.*

*CTCC\_GEOM: number of the iteration of contact continuous method at the time of the loop on the geometry.*

*column is marked by X as long as one did not converge.*

*CTCC\_FROT: number of the iteration of contact continuous method at the time of the loop on the threshold of*

*friction. The column is marked by X as long as one did not converge.*

*CTCC\_CONT: number of the iteration of contact continuous method at the time of the loop on the state of contact*

(active constraints). The column is marked by X as long as one did not converge.

Composite types (posts several columns):

**STANDARD:** standard posting (by defect) of the table of convergence. Contains:

- The number of the iteration of Newton (ITE\_NEWT)
- All columns necessary according to functionalities' activated (linear research, contact, piloting,...)
- The value of residues (RESI\_MAXI and RESI\_RELA)

**MINIMUM:** minimum posting of the table of convergence. Contains:

- The number of the iteration of Newton (ITER\_NEWT)
- The value of residues (RESI\_MAXI and RESI\_RELA)

**Note:**

- One cannot require more than sixteen columns (16 columns of 16 characters, that is to say a width total of 256)
- The columns are cumulable: one can ask for MINIMUM posting and add one unspecified column
- One can have several times the same column
- As long as "X" is posted in column ITER\_NEWT, calculation did not converge. This depends of course on the value of the residues but also of the convergence of the contact or on De Borst.
- For the method of contact continues, the iterations of Newton constitutes an internal loop with three other loops (CTCC\_GEOM, CTCC\_FROT and CTCC\_CONT). ITER\_NEWT is not thus not in first position in "STANDARD" mode and it is the marking of columns CTCC\_\* who exploits the part of final Justice of the Peace convergence.

### ***3.17.3 Operand INFO\_RESIDU***

***INFO\_RESIDU***

=

***“NOT”,  
[DEFECT]***

***“YES”***

***This operand makes it possible to add a column for each residue evaluated (RESI\_RELA, RESI\_MAXI and RESI\_REFE). This column will indicate the node where the residue is maximum, which can help the user when there are difficulties of convergence. For example, to see whether the material were badly definite with an incorrect value on an element.***

***This option is strictly equivalent to the addition of columns RELA\_NOEU, RELA\_MAXI or RELA\_REFE when one completely describes the posting of the table of convergence but allows to post information on the nodes when one is in STANDARD” or “MINIMUM” mode “, without needing to describe all the other columns.***

### ***3.17.4 Operands LONG\_R, PREC\_R and LONG\_I***

***LONG\_R***

= /

12

***[DEFECT]***

/

***long\_r***

***[I]***

***PREC\_R =***

/ 5

***[DEFECT]***

/

***prec\_r***  
**[I]**  
***LONG\_I =***

***/ 6***  
**[DEFECT]**

***/***  
***long\_i***  
**[I]**

*These operands make it possible to modify the posting of information in the table of convergence. All the columns have a fixed width of 16 characters. When information is a reality, one can require a personalized posting: the length long\_r of posted reality (maximum 16) and numbers it significant figures.*

*When it is an entirety, one can regulate the length by long\_i. For a it, character string format is always of 16 characters.*

### ***3.18 Operand OBSERVATION***

*The syntax of this key word common to order DYNA\_NON\_LINE is described in the document [U4.53.01].*

### ***3.19 Operand SOLV\_NON\_LOCAL***

*The syntax of this key word is identical to key word SOLVEUR describes in the document [U4.50.01].  
With  
to use for a nonlocal model.*

### ***3.20 Operand LAGR\_NON\_LOCAL***

*The integration of nonlocal laws of behavior imposes the resolution of a total problem (on all the structure): the minimization of a functional calculus energy (the expression of Lagrangian increased) by  
report/ratio with a scalar nodal variable.*

*The resolution of this problem is carried out by means of an algorithm primal newton and dual BFGS compound, which consists of two phases:*

- Résolution of the primal problem:*
  - Minimization compared to the variable interns nonlocal and its gradient (cham\_elem)*
  - Minimization compared to the variable interns with the nodes (cham\_no)*
  - Primal Test of convergence: the largest component of the assembled residue*
- Résolution of the dual problem: (Maximization compared to the multipliers of Lagrange)*

- *Calculation of a direction of descent BFGS*
- *Linear Research by method of Wolfe*
- *Dual Test of convergence: the largest component of the gradient*
- *Reactualization of the multipliers of Lagrange*

***ITER\_PRIM\_MAXI: iterprimmax (10 per defect)***

*Iteration count maximum for the resolution of the primal problem.*

*Instruction manual*

***U4.5- booklet: Method of resolution***

*HT-62/06/004/A*

---

***Code\_Aster*** ®

*Author (S):*

***Mr. Key ABBAS***

:

*U4.51.03-H1 Page:*

33/34

***RESI\_PRIM\_ABSO: resiprimab***

*Precision for the test of convergence for the primal problem.*

***ITER\_DUAL\_MAXI: iterdmax (50 per defect)***

*Iteration count maximum for the resolution of the dual problem.*

***RESI\_DUAL\_ABSO: residabso***

*Precision for the test of convergence for the dual problem.*

***R: rho (1000 per defect)***

*Coefficient of penalization of Lagrangian increased.*

**Note:**

*As the precision of the dual problem strongly depends on that of the primal problem, one advise to choose a better precision for the primal problem, for example 100 or 1000 times more than for the dual problem.*

**3.21 Operand  
INFORMATION**

**INFORMATION**

**:**  
**inf**

*Allows to carry out in the file message various intermediate impressions in the presence of unilateral contact treaty by the method of the active constraints.*

*inf =  
1 impression of the list of the nodes in contact after convergence with each iteration of Newton.*

*= 2  
idem 1 plus impression of associations/dissociations of nodes enters iterations of the method of the active constraints.*

*Other impressions are made systematically during nonlinear calculation, independently value assigned to the key word INFORMATION: they are the impressions of the residues and the increments relative of displacement during iterations of Newton.*

**3.22 Operand  
TITRATE**

**TITRATE: tx**

*tx is the title of calculation. It will be printed at the head results. See [U4.03.01].*

**COMP\_INCR**

**/ COMP\_INCR:**

*This key word factor makes it possible to define the relations of behavior for which history material influences its behavior: majority of the laws of behavior (in particular in plasticity) are written in an incremental way then. The history seen by material is stored in the internal variables. One can have in same calculation certain parts of structure obeying with various incrémentaux behaviors (COMP\_INCR) and other parts obeying various elastic behaviors (COMP\_ELAS).*

*Certain models of behaviors were not developed in plane constraint.*

*However, key word ALGO\_C\_PLAN [§3.3.5] makes it possible to add this condition to all them models: algorithm called "DEBORST" allows a taking into account of the assumption of plane constraints on the level of the algorithm of balance (contrary to the models of "ANALYTICAL" behavior developed explicitly in the language Aster - in plane constraints, which adopt this approach on the level of the integration of the laws of behavior). One can thus also assign a nonlinear law to the elements of structure DKT, COQUE\_3D and PIPE.*

*In the same way, for the uses using a monodimensional state of stresses (POU\_D\_EM, POU\_D\_TGM, GRILLE\_MEMBRANE, BAR), to be able to use the behaviors 3D, it is necessary to use key word ALGO\_1D (METHOD = "DEBORST").*

### **3.1.1.1 Models**

**traditional**

**Unless otherwise specified, all the models can include a dependence compared to temperature.**

**/“ELAS”**

**Relation of elastic behavior incremental: it makes it possible to take into account initial displacements and constraints given under key word ETAT\_INIT. Data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01], under key word ELAS (\_FO).**

**Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, HULL, PIPE, COQUE1D, 3D\_DIS, 2D\_DIS, INCO, LOUSE, BAR, PMF, GRID.**

**A number of internal variables: 1**

**Significance: V1: vacuum thus is worth always zero (with the deformations of the type SIMO\_MIEHE**

**only cf [§3.3.3], V1 is equal to the trace of the tensor of elastic strain divided by 3 used for formulation SIMO\_MIEHE).**

**/“VMIS\_ISOT\_TRAC”**

**Relation of behavior of elastoplasticity of Von Mises with nonlinear isotropic work hardening. The curve (,) in simple traction is provided in operator DEFI\_MATERIAU [U4.43.01], under the key word TRACTION (cf [R5.03.02] for more details). One can possibly define several traction diagrams according to the temperature. One must also inform the key word ELAS (\_FO) in operator DEFI\_MATERIAU. It is the relation of behavior per defect for incrémentaux behaviors.**

**If a traction diagram is provided, the YOUNG modulus used for the relation of behavior is that calculated starting from the first point of the traction diagram, that used for the calculation of the elastic matrix (see key word NEWTON [U4.51.03]) is that given in ELAS (\_FO).**

**Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, HULL, PIPE, COQUE1D, BAR, PMF and INCO.**

**A number of internal variables: 2**

**Significance: V1: cumulated plastic deformation, V2: indicator of plasticity (0 for rubber band, 1 for plastic). With the deformations of the type SIMO\_MIEHE only (cf [§3.3.3]), one internal variable additional V3: trace tensor of elastic strain divided by 3 used for formulation SIMO\_MIEHE.**

**Supported nonlocal modeling (see [§ 3.3.1.3]): GRAD\_VARI**

**/“VMIS\_ISOT\_LINE”**

**Relation of behavior of elastoplasticity of Von Mises with linear isotropic work hardening. data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01] under key words ECRO\_LINE (\_FO) and ELAS (\_FO) (cf [R5.03.02]).**

**Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, HULL, PIPE, COQUE1D, INCO, PMF and BAR.**

**A number of internal variables: 2**

**Significance (except modeling BARS): V1: cumulated plastic deformation, V2: indicator of**

*plasticity (0 for rubber band, 1 for plastic). With the deformations of the type SIMO\_MIEHE only (cf [§3.3.3]), an internal variable additional V3: trace tensor of elastic strain divided by 3 used for formulation SIMO\_MIEHE.*

*Supported nonlocal modeling (see [§ 3.3.1.3]): GRAD\_VARI*

*/“VISC\_ISOT\_LINE”*

*Visco-elastoplastic relation of behavior in great deformations (formulation SIMO\_MIEHE only). The plastic model is VMIS\_ISOT\_LINE i.e. with work hardening isotropic linear. The data necessary of the field material are provided in the operator DEF1\_MATERIAU [U4.43.01] under key words ECRO\_LINE (\_FO), ELAS (\_FO). The law of viscosity is a hyperoblic law in sine (cf [R5.03.21]). The viscous parameters are to inform under key word VISC\_SINH in operator DEF1\_MATERIAU.*

*Supported modelings: 3D, D\_PLAN, AXIS and INCO.*

*A number of internal variables: 3*

*Significance: V1: cumulated plastic deformation, V2: indicator of plasticity (0 for rubber band, 1 for plastic), V3: trace tensor of elastic strain divided by 3 used for formulation SIMO\_MIEHE.*

*/“VISC\_ISOT\_TRAC”*

**Visco-elastoplastic relation of behavior in great deformations (formulation SIMO\_MIEHE only). The plastic model is VMIS\_ISOT\_TRAC i.e. with work hardening isotropic nonlinear. The curve (,) in simple traction is provided in the operator DEF1\_MATERIAU [U4.43.01], under the key word TRACTION (cf [R5.03.02] for more details). One can possibly define several traction diagrams according to the temperature. One must also to inform key word ELAS (\_FO) in operator DEF1\_MATERIAU. The law of viscosity is a law in hyperbolic sine (cf [R5.03.21]). The viscous parameters are to inform under key word VISC\_SINH in operator DEF1\_MATERIAU.**

**Supported modelings: 3D, D\_PLAN, AXIS and INCO.**

**A number of internal variables: 3**

**Significance: V1: cumulated plastic deformation, V2: indicator of plasticity (0 for rubber band, 1 for plastic), V3: trace tensor of elastic strain divided by 3 used for formulation SIMO\_MIEHE.**

**/“VMIS\_CINE\_LINE”**

**Relation of behavior of elastoplasticity of Von Mises with linear kinematic work hardening. The data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key words ECRO\_LINE (\_FO) and ELAS (\_FO) (cf [R5.03.02] for more details).**

**Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), HULL, PIPE, COQUEID, INCO, BAR and PMF.**

**A number of internal variables (except modelings BARS and PMF): 7**

**Significance: V1 with V6: 6 components of the tensor of kinematic work hardening X, V7: indicator of plasticity (0 for rubber band, 1 for plastic).**

**A many internal variables for modeling BAR: 2**

**Significance: V1: kinematic work hardening X.**

**V2: indicator of plasticity**

**/“VMIS\_ECMI\_TRAC”**

**Relation of behavior of elastoplasticity of Von Mises with combined, kinematic work hardening linear and isotropic nonlinear (cf [R5.03.02] for more details). Isotropic work hardening is given by a traction diagram (,) or possibly by several curves if those  $C_i$  depend on the temperature. The characteristics of material are provided in the operator DEF1\_MATERIAU [U4.43.01], under key words PRAGER (\_FO) (for kinematic work hardening), TRACTION (for isotropic work hardening) and ELAS (\_FO).**

**Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE and COQUEID (by DEBORST key word ALGO\_ID: modelings BARS, PMF, GRID).**

### **3.1.1.2 local Models with damage**

#### **Caution:**

**The response of a model of local behavior with damage is dependent on grid.**

**/“ENDO\_FRAGILE”**

**Relation of elastic behavior fragile. It is about a local modeling with damage scalar and with negative linear isotropic work hardening (cf [R5.03.18] for more details). characteristics of material are defined in operator *DEFI\_MATERIAU* [U4.43.01] under key words *ECRO\_LINE* (*\_FO*) (negative *DSDE*) and *ELAS* (*\_FO*).**

**Supported modelings: 3D, *D\_PLAN*, *AXIS*, *C\_PLAN*, *INCO*, *HULL*, *PIPE* and *COQUE1D*.**

**A number of internal variables: 2**

**Significance: *V1*: value of the damage, *V2*: indicator of damage (0 if the damage is worth 0, 1 if the damage is higher than 0).**

**Supported nonlocal modeling (see [§ 3.3.1.3]): *GRAD\_VARI* and *GRAD\_EPSI*.**

**/“ENDO\_ISOT\_BETON”**

**Relation of elastic behavior fragile. It is about a local modeling with damage scalar and with negative linear isotropic work hardening which distinguishes behaviour in traction and in compression of the concrete (cf [R7.01.04] for more details). The characteristics of material are defined in operator *DEFI\_MATERIAU* [U4.43.01] under key words *BETON\_ECRO\_LINE* and *ELAS*.**

**Supported modelings: 3D, *D\_PLAN*, *AXIS*, *C\_PLAN* (by *DEBORST*, key word *ALGO\_C\_PLAN* [§3.3.5]), *INCO*, *HULL*, *PIPE*, *COQUE1D*.**

**A number of internal variables: 2**

**Significance: *V1*: value of the damage, *V2*: indicator of damage (0 for mode rubber band (null damage), 1 if damaged, 2 if broken (damage equal to 1)).**

**Supported nonlocal modeling (see [§ 3.3.1.3]): *GRAD\_EPSI***

**/“ENDO\_ORTH\_BETON”**

**Relation of anisotropic behavior of the concrete with damage [R7.01.09]. It is about one local modeling of fascinating damage of account refermeture of the cracks.**

*characteristics of materials are defined in operator DEFI\_MATERIAU under the key words ELAS and ENDO\_ORTH\_BETON.*

*Supported modelings: 3D, D\_PLAN, AXIS (by DEBORST: C\_PLAN...)*

*A number of internal variables: 7*

*Significance: V1 with V6: tensor of damage of traction  
V7: damage of compression*

**Note:**

*Three following models “ROUSSELIER” (elastoplastic model), “ROUSS\_PR” (model elastoplastic) and “ROUSS\_VISC” (model elastoviscoplastic) are three versions different from the model of Rousselier. This model is a relation of behavior élasto (visco) plastic which makes it possible to account for the growth of the cavities and to describe ductile rupture in steels. Apart from the with dimensions viscous plastic/, the difference essential resides in the way in which the great deformations are treated. For model*

*“ROUSSELIER” it acts of a standard formulation Simo\_Miehe (DEFORMATION: “SIMO\_MIEHE” to see [§3.3.3]) and for the two others of a formulation type “PETIT\_REAC” (DEFORMATION: “PETIT\_REAC” to see [§3.3.3]). On different examples treated in plasticity, it was noted that model “ROUSS\_PR” needs much more iterations of Newton to converge compared to model “ROUSSELIER”.*

*Instruction manual*

*U4.51.11-B1 Page:*

14/46

*It should be also noted that these three models treat in a different way broken material. In models “ROUSS\_PR” and “ROUSS\_VISC”, when porosity reaches a porosity limit, one considers broken material. The behavior is then replaced by a fall imposed constraints. To activate this modeling of broken material, it is necessary then to inform in operator DEF1\_MATERIAU [U4.43.01], under the key word ROUSSELIER (\_FO), two coefficients “PORO\_LIMI” and “D\_SIGM\_EPSI\_NORM”. For “ROUSSELIER”, one does not do anything in particular because the constraint tends naturally towards zero when porosity tends towards one. The two preceding parameters can be indicated but do not have impact on the model.*

### ***/“ROUSSELIER”***

*Elastoplastic relation of behavior. It makes it possible to account for the growth of cavities and to describe the ductile rupture. This model gets busy exclusively with the key word DEFORMATION: “SIMO\_MIEHE” (see [§3.3.3]). Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key words ROUSSELIER (\_FO) and ELAS (\_FO) (cf [R5.03.06] for more details). To facilitate integration this model, it is advised systematically to use the total recutting of the step of time (see [§3.7.4], key word SUBD\_PAS). This model is not developed in plane constraint. Moreover, with key word SIMO\_MIEHE, one cannot use the plane constraints by the method DEBORST.*

*Supported modelings: 3D, D\_PLAN, AXIS.*

*A number of internal variables: 9*

*Significance: V1: cumulated plastic deformation, V2: value of porosity, V3 with V8: 6 components of a tensor eulérien in great deformations of elastic strain, V9: indicator of plasticity (0 so elastic, 1 so plastic with regular solution, 2 so plastic with singular solution).*

### ***/“ROUSS\_PR”***

*Elastoplastic relation of behavior. It makes it possible to account for the growth of cavities and to describe the ductile rupture. This model gets busy exclusively with the key words DEFORMATION: “PETIT\_REAC” or “SMALL”, to see [§3.3.3], (to use modeling preferably “PETIT\_REAC” because it is a model great deformations). Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key words ROUSSELIER (\_FO) and ELAS (\_FO) (cf [R5.03.06] for more details). One also can to take into account the nucleation of the cavities. It is then necessary to inform the parameter YEAR (key word not activated for model ROUSSELIER and ROUSS\_VISC) under ROUSSELIER (\_FO) to facilitate the integration of this model, it is advised to use the local automatic recutting of the step of time (see [§3.13.6], key word ITER\_INTE\_PAS).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 3*

*Significance: V1: cumulated plastic deformation, V2: value of porosity, V3: indicator of plasticity (0 so elastic, 1 so plastic).*

***/"ROUSS\_VISC"***

*Relation of behavior élasto-visco-plastic. It makes it possible to account for the growth cavities and to describe the ductile rupture. This model gets busy exclusively with the key words DEFORMATION: "PETIT\_REAC" or "SMALL", to see [§3.3.3], (to take modeling "PETIT\_REAC" because it is a model great deformations). Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key words VISC\_SINH, ROUSSELIER (\_FO) and ELAS (\_FO) (cf [R5.03.06] for more details). To facilitate the integration of this model, it is advised to use the local automatic recutting of the step of time (see [§3.12.5], key word ITER\_INTE\_PAS). For the integration of this law, one - method is available and one advises to use an semi-implicit integration i.e.:*

*Significance: V1 with V6: viscoplastic deformation, V7: cumulated plastic deformation, V8: isotropic work hardening, V9: damage.*

### **3.1.1.3 nonlocal Models**

***There are two types of laws in nonroom.***

***First is activated in AFFE\_MODELE by the key word MODELING: “3D\_GRAD\_EPSI”, “D\_PLAN\_GRAD\_EPSI” or “C\_PLAN\_GRAD\_EPSI”. They are nonlocal laws regularized on deformation. One defines a field of regularized deformation, dependent on the traditional local deformation by***

***a regularizing operator who aims to limit the concentrations of deformations (Cf [R5.04.02] for more detail).***

***The second type is activated in AFFE\_MODELE by the key word MODELING: “3D\_GRAD\_VARI”, “D\_PLAN\_GRAD\_VARI”, “C\_PLAN\_GRAD\_VARI” or “AXIS\_GRAD\_VARI”.***

***They are nonlocal laws here where the gradient of the internal variables of the local model intervenes.***

***The key word MODELING makes it possible to activate in operator STAT\_NON\_LINE the key word LAGR\_NON\_LOCAL (and SOLV\_NON\_LOCAL), algorithm of resolution specific to the models not buildings.***

*Any model written in nonroom involves the introduction of a characteristic of material additional, the characteristic length which is defined under the key word factor NON\_LOCAL of operator DEFI\_MATERIAU.*

***The response of a nonlocal modeling is independent of the grid.***

*The nonlocal models being sophisticated than their equivalent locally, calculation is more expensive in computing times. The first modeling GRAD\_EPSI is nevertheless faster than modeling GRAD\_VARI.*

*The various laws available in nonlocal are as follows:*

***/"ENDO\_FRAGILE"***

*Cf [R5.04.02] for more detail for the nonlocal version.*

*Supported nonlocal modeling: GRAD\_VARI and GRAD\_EPSI*

*A number of variables intern for modeling GRAD\_EPSI: 2*

*Significance: V1: value of the damage, V2: indicator of damage (0 if the damage is worth 0, 1 if the damage is higher than 0).*

*A number of variables intern for modeling GRAD\_VARI: 6*

*Significance: V1: value of the damage, V2 with V4: 3 components of the gradient of the damage, V5*

*: variable useful for the formulation for gradient, V6*

*: indicator*

*of damage (0 so elastic, 1 if the damage is higher than 0, 2 if broken (damage of 0.999)).*

**/“ROUSSELIER”**

*Cf [R5.04.02] for more detail for the nonlocal version.*

*Supported nonlocal modeling: GRAD\_VARI*

*A number of internal variables: 12*

*Significance:*

*V1: cumulated plastic deformation,*

*V2 with V4: gradient of the plastic deformation cumulated along axes X, y, Z, respectively,*

*V5: porosity,*

*V6 with V11: elastic strain used for SIMO\_MIEHE,*

*V12: indicator of plasticity*

*(0 so elastic,*

*1 so plastic and regular solution,*

*2 so plastic and singular solution).*

### **3.1.1.4 Models describing the phenomenon of progressive deformation**

**/“VISC\_TAHERI”**

*Relation of behavior (visco) - plastic modelling the response of materials under loading cyclic plastic. The data necessary of the field material are provided in the operator DEF1\_MATERIAU [U4.43.01], under key words TAHERI (\_FO) for the description of work hardening, LEMAITRE (\_FO) for viscosity and ELAS (\_FO) (cf [R5.03.05] for more details). In the absence of LEMAITRE, the law is purely plastic.*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 9*

*Significance: V1: cumulated plastic deformation, V2: constraint of peak, V3 with V8: 6 components tensor of plastic deformations due to the last discharge, V9: loadmeter/discharge (0 for elastic discharge, 1 if traditional plastic load, 2 if plastic load on two surfaces, 3 if pseudo-discharge).*

**/“POLY\_CFC”**

***Relation of behavior élasto-visco-plastic based on the polycrystalline approach, developed in the Center of Materials of the School of the Mines of Paris. It makes it possible to treat materials with cubic structure with Centered Face having an isotropic texture, under monotonous loadings or cyclic. The data necessary of the field material are provided in the operator `DEFI_MATERIAU [U4.43.01]`, under key words `POLY_CFC (_FO)` and `ELAS (_FO)` (cf [R5.03.13] for more details). The integration of this model can be done only with method `RUNGE KUTTA 2` (see [§3.13.7], key word `RESO_INTE`).***

***Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE, BAR and COQUE1D.***

***A number of internal variables: 1688  
Significance: Cf [R5.03.13]***

### ***3.1.1.5 Behaviors of microstructures***

***Models describing the behavior of microstructures.***

***/“POLYCRYSTAL”***

***/“MONOCRYSTAL”***

***COMPOR = comp [compor]***

***These models make it possible to describe the behavior of a monocrystal or a polycrystal of which their relations of behavior are provided via the concept compor, resulting from `DEFI_COMPOR`. a many internal variables are a function of the choices carried out in `DEFI_COMPOR`; for more specified to consult [R5.03.11].***

### **3.1.1.6 Behaviors specific with the fuel pins**

**/“ZIRC\_CYRA2”**

*Relation of viscoplastic behavior nonlinear for the sheath in Zircaloy of the pencil fuel (law of CYRANO2). This relation describes creep with a formulation in work hardening for time (time-hardening). The data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key words ZIRC\_CYRA2 and ELAS (Cf [R5.03.08] for more details). For the integration of this law, one advises to use one semi-implicit integration i.e.:*

**PARAM\_THETA:**  
**0.5**  
**CONVERGENCE**

:  
**(RESO\_INTE**  
:  
**“IMPLICIT”**  
)

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, HULL, PIPE, BARS and COQUE1D.*

*A number of internal variables: 2*

*Significance: V1: cumulated plastic deformation, V2: vacuum thus is worth always 0.*

**/“LMARC”**

*Phenomenologic model developed with the LMA-RC of Besancon to obtain a fine description behavior of the tubes of sheath in Zircaloy of the fuel pin of the power stations REFERENCE MARK which present an anisotropic and strongly viscous mechanical behavior [R5.03.10].*

*The model is available in 3D, plane deformations (D\_PLAN), and axisymetry (AXIS) under name of LMARC.*

*Internal variables: 20*

- *three variables of kinematic work hardening. X, X1, X2 (18 variables intern)*
- *cumulated viscoplastic deformation p*
- *indicating of plasticity*

*The properties material are defined in DEF1\_MATERIAU under key words ELAS (\_FO) and LMARC (\_FO).*

### ***/“ZIRC\_EPRI”***

*Relation of viscoplastic behavior nonlinear for the sheath in Zircaloy of the pencil fuel (used in program ESCORE of the EPRI). This relation describes creep with a formulation in work hardening for time (time-hardening). Data necessary of field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key words ZIRC\_EPRI and ELAS (cf [R5.03.08] for more details). For the integration of this law, one advise to use an semi-implicit integration i.e.:*

*PARAM\_THETA:

## ***/GATT\_MONNERIE***

*The thermomechanical law of behavior of fuel “GATT-Monerie” makes it possible to simulate tests of indentation. This law of behavior is an isotropic élasto-viscoplastic law without work hardening whose specificities are:*

- the potential of dissipation is the sum of two potentials of the Norton type (without threshold),*
- the fuel having a residual porosity likely to evolve/move encompression (thickening), this potential depends, in addition to the equivalent constraint, of the constraint hydrostatic.*

*The two internal variables of this model are the cumulated plastic deformation and the fraction voluminal of porosity.*

## ***/“GRAN\_IRRA\_LOG”***

*Relation of behavior of creep and growth under irradiation for the assemblies fuels.*

*The field of fluence is defined by key word AFFE\_VARC of order AFFE\_MATERIAU. characteristics of the behavior are provided in operator DEFI\_MATERIAU [U4.43.01], under key word GRAN\_IRRA\_LOG. The growth being done only according to one direction, it is necessary in the cases 3D and 2D to give the direction of the growth by the operand ANGL\_REP of the MASSIVE key word of operator AFFE\_CARA\_ELEM. Characteristics of creep (relation of behavior of the type LEMAITRE modified for the integration of the model is carried out by an semi-implicit method (coded into hard thus nothing in particular to be specified by the user).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, PIPE. PMF*

*A number of internal variables: 1  
V1: cumulated equivalent viscoplastic deformation,*

**/"LEMAITRE\_IRRA"**

*Relation of behavior of creep and growth under irradiation for the assemblies  
fuels.*

*The field of fluence is defined by key word AFFE\_VARC of order AFFE\_MATERIAU.  
characteristics of the behavior are provided in operator DEFI\_MATERIAU [U4.43.01],  
under key word LEMAITRE\_IRRA. The growth being done only according to one direction, it is  
necessary in the cases 3D and 2D to give the direction of the growth by the operand  
ANGL\_REP of the MASSIVE key word of operator AFFE\_CARA\_ELEM. For the beams, creep and it  
growth take place only in the axial direction of the beam: in the other directions, it  
behavior is elastic. For modelings 1D (LOUSE), there are the choice of the diagram  
of integration (implicit or semi-implicit), but one advises to use an semi-implicit integration  
i.e.:*

*PARAM\_THETA:  
0.5*

## CONVERGENCE

:  
 (RESO\_INTE  
 :  
 “IMPLICIT”  
 )

*For all other modelings, the integration of the model is carried out by a method semi-implicit (coded into hard thus nothing in particular to be specified by the user).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, PIPE and LOUSE (only POU\_D\_T and POU\_D\_E).*

*A number of internal variables: 2*

*V1: cumulated plastic deformation,*

*V2: null*

*For modeling LOUSE:*

*V1: cumulated plastic deformation,*

*V2: value of the irradiation at the point of Gauss considered.*

### **/“LMARC\_IRRA”**

*Relation of behavior of viscoplasticity of the LMARC with taking into account of the irradiation for fuel assemblies. The field of fluence is defined by key word AFFE\_VARC of order AFFE\_MATERIAU. The characteristics of the behavior are provided in operator DEFI\_MATERIAU [U4.43.01], under key word LMARC\_IRRA.*

*For the beams, creep takes place only in the axial direction of the beam: in the other directions, the behavior is elastic.*

*Supported modelings: LOUSE (only POU\_D\_T and POU\_D\_E).*

*A number of internal variables: 5*

- *three variables of kinematic work hardening. X, X1, X2*
- *cumulated viscoplastic deformation p*
- *value of the irradiation at the point of Gauss considered.*

### **/“LEMA\_SEUIL”**

*Viscoplastic relation between behavior and threshold under irradiation for the assemblies fuels.*

*The field of fluence is defined by key word AFFE\_VARC of order AFFE\_MATERIAU. characteristics of the growth are provided in operator DEFI\_MATERIAU [U4.43.01], under key word LEMA\_SEUIL. The integration of the model is carried out by an semi-implicit method (coded into hard thus nothing in particular to be specified by the user).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, PIPE.*

*A number of internal variables: 2*

*V1: cumulated plastic deformation,*

**3.1.1.7 Behaviors****specific*****with the discrete elements and beams******/"DIS\_GRICRA"***

*Behavior DIS\_GRICRA is pressed on discrete elements with 2 nodes, with 6 ddl by node (translation+rotation. From the total degrees of freedom, one solves 3 subsystems: 2 bosses + 1 spring for which one takes stock of the forces. One is reduced then to the system total by expressing the force total and the moment. The law of behavior on each under system is of the plasticity type with positive work hardening in the tangential directions with the discrete one to model the slip, and of the unilateral elastic type in the direction of discrete for to model the contact.*

*The parameters characterizing the contact and friction are provided in the operator DEFI\_MATERIAU [U4.43.01], under key word DIS\_GRICRA. Contrary to the other discrete ones, one*

*does not take into account the characteristics of rigidity of AFFE\_CARA\_ELEM. The matrix of rigidity of discrete must thus be taken null in AFFE\_CARA\_ELEM. Rigidity is only exit of the parameters in DEFI\_MATERIAU.*

*The unilateral contact takes place in the direction X data by mesh SEG2 of the discrete element, and the slip takes place in the direction Y given by the key word ORIENTATION of*

*AFFE\_CARA\_ELEM* (cf [R5.03.17] for more details). The tangent matrix is nonsymmetrical.  
Supported modelings: *DIS\_TR*

A number of internal variables: 12  
Significance:

### ***/"DIS\_CONTACT"***

*Model of contact with friction of COULOMB, relation of isothermal behavior of type elastoplastic, being pressed on a discrete element with 2 nodes. Parameters characterizing it contact and friction is provided in operator DEFI\_MATERIAU [U4.43.01], under the word key DIS\_CONTACT. The values of rigidities are given by AFFE\_CARA\_ELEM [U4.42.01] (word key DISCRETE). The unilateral contact takes place in the direction X data by mesh SEG2 of the discrete element, and the slip takes place in the direction Y given by the key word ORIENTATION*

*AFFE\_CARA\_ELEM* (cf [R5.03.17] for more details). However, this modeling described not well behaviour in rotation of the connection, particularly on the level of discharge. It is preferable to use *DIS\_GRICRA*.

Supported modelings: *3D\_DIS*

A number of internal variables: 6  
Significance: V1: indicator of contact/friction (1 if slip, 0 so not slip, -1 if separation), V2: plastic displacement cumulated around local direction Z, V3: plastic displacement cumulated around local direction X, V4 with V6: vacuums thus equal to 0.

### ***/"DIS\_CHOC"***

*Isothermal model of shock with friction of Coulomb being pressed on a discrete element with 1 or 2 nodes. The parameters characterizing the shock and friction are provided in the operator DEFI\_MATERIAU [U4.43.01], under key word DIS\_CONTACT. In comparison with DIS\_CONTACT, this model is to be used preferentially in dynamics (writing of the behavior of speed) [R5.03.17].*

Supported modelings: *3D\_DIS*

A number of internal variables: 7

### ***Note:***

*The internal variables describe the behavior in the tangential plan defined by*

*local directions y and Z, which are defined compared to the normal direction of shock X. Significance: V1 and V2: displacements (differential between nodes 1 and 2 if there is one net SEG2) in local directions y and Z, respectively, V3 and V4: speed (differentials between nodes 1 and 2 if there is a mesh SEG2) in the directions local y and Z, respectively, V5 and V6: forces intern in the local directions y and Z, respectively, V7: indicator of adherence (0 if slip, 1 if adherence).*

***/"VMIS\_POU\_LINE"***

*Relation of elastoplastic behavior isothermal of the elements of beam with total criterion of plasticity. The data necessary of the field material are provided in the operator DEF1\_MATERIAU [U4.43.01], under key word VMIS\_POUTRE, and ECRO\_LINE for work hardening*

*who is linear (cf [R5.03.30] for more details). The integration of this model can be done is with an implicit method is with method RUNGE KUTTA 4 (see [§3.13.7], key word RESO\_INTE).*

*Supported modelings: LOUSE*

*A number of internal variables: 9*

*Significance: V1: plastic deformation along axis X, V2 with V4: plastic curve according to*

*axes Y, Z and X respectively, V6 and V7: internal variables used in post treatment for calculation of the pylons, V8 and V9: plastic curve cumulated along the axis Y and Z respectively.*

### ***/"VMIS\_POU\_FLEJOU"***

*Relation of elastoplastic behavior isothermal of the elements of beam with total criterion of plasticity. The data necessary of the field material are provided in the operator DEF1\_MATERIAU [U4.43.01], under key word VMIS\_POUTRE, and ECRO\_FLEJOU for work hardening*

*who is nonlinear (cf [R5.03.30] for more details). The integration of this model can be done either with an implicit method or with method RUNGE KUTTA 4 (see [§3.13.7], key word RESO\_INTE).*

*Supported modelings: LOUSE*

*A number of internal variables: 9*

*Significance: V1: plastic deformation along axis X, V2 with V4: plastic curve according to axes Y, Z and X respectively, V6 and V7: internal variables used in post treatment for calculation of the pylons, V8 and V9: plastic curve cumulated along the axis Y and Z respectively.*

### ***/"WEAPON"***

*Relation of elastoplastic behavior isothermal for the conductor arrangements. Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key word ARMS.*

*Supported modelings: 3D\_DIS*

*A number of internal variables: 1*

*Significance: V1: maximum value attack of the quantity in absolute value ( $u_y$  ule) where  $u_y$  is it displacement in the local direction there of mesh SEG2 and displacement limits field rubber band.*

### ***/"ASSE\_CORN"***

*Relation of elastoplastic behaviour isothermal for the assemblies bolted of angles of pylons. The data necessary of the field material are provided in the operator DEF1\_MATERIAU [U4.43.01], under key word ASSE\_CORN.*

*Supported modelings: 3D\_DIS*

*A number of internal variables: 4*

*Significance: V1: displacement reduces maximum equivalent reached for the first mechanism of deformation, V2: displacement reduces maximum equivalent reached for the second mechanism of deformation, V3: indicator of plasticity, V4: vacuum thus is worth 0.*

**/“DIS\_GOUJ2E\_PLAS”**

*Model to represent the local behavior of a net of pin of assembly threaded (element discrete). The behavior is elastic safe everywhere along local axis Y. In this direction, it acts of an isothermal law of elastoplasticity of Von Mises with nonlinear isotropic work hardening*

*(Cf [R5.03.17] for more details). The data necessary of the field material are provided in operator `DEFI_MATERIAU` [U4.43.01], under the key words `TRACTION` (for the direction local Y) and `ELAS`. The curve indicated in `TRACTION` represents actually the curve effort of shearing-jump of displacement Y of a local calculation of a net and `ELAS` defines the rigidity affected to discrete for the other directions (in fact X room)).*

*Supported modelings: 2D\_DIS\_T.*

*A number of internal variables: 2*

*Significance: V1: plastic displacement cumulated, V2: indicator of plasticity (0 so elastic, 1 if plastic).*

***/"DIS\_GOUJ2E\_ELAS"***

*Model to represent the local elastic behavior of a net of pin of threaded assembly (discrete element). The behavior is elastic everywhere (cf [R5.03.17] for more details). data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01], under key word ELAS.*

*Supported modelings: 2D\_DIS\_T.*

*A number of internal variables: 1*

*Significance: V1: vacuum (thus 0 are worth).*

***/"VMIS\_ASYM\_LINE"***

*Relation of isothermal behavior uniaxial of elastoplasticity of Von Mises with work hardening isotropic with different elastic limits in traction and compression. This model asymmetrical of elements of bar allows to model the interaction between a control or a cable buried and ground. The data necessary of the field material are provided in the operator DEFI\_MATERIAU [U4.43.01], under key word ECRO\_ASYM\_LINE (cf [R5.03.09] for more details).*

*Supported modeling: BAR*

*A number of internal variables: 4*

*Significance: V1: plastic deformation cumulated in traction, V2: indicator of plasticity in traction, V3: plastic deformation cumulated in compression, V4: indicator of plasticity in compression.*

### ***Mechanical 3.1.1.8 Models with effects of the metallurgical transformations***

*The following relations of behavior apply to a material which undergoes changes of metallurgical phases (cf [R4.04.02] for more detail).*

*Significance of the letters for the metallurgical behaviors:*

***P***

***= plastic behavior***

**V**

= *viscoplastic behavior*

*IT = linear isotropic work hardening*

*Nonlinear INL = isotropic work hardening*

*Linear CL = kinematic work hardening*

*Pt = plasticity of transformation*

*RE = restoration of metallurgical work hardening of origin*

*One can activate by key word RELATION\_KIT [§3.3.2] of operator STAT\_NON\_LINE two types of*

*material, is STEEL which comprises with more the 5 different metallurgical phases, that is to say ZIRC which*

*comprise with more the 3 different metallurgical phases.*

### ***3.1.1.9 Behavior for the concrete***

#### ***/"BETON\_DOUBLE\_DP"***

*Three-dimensional relation of behavior used for the description of the behavior not linear of the concrete. It comprises a criterion of Drucker Prager in traction and a criterion of Drucker*

*Prager in compression, uncoupled. The two criteria can have a lenitive work hardening. The data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01], under key words BETON\_DOUBLE\_DP and ELAS (\_FO) (cf [R7.01.03] for more details). To facilitate the integration of this model, one can use local automatic recutting step of time (see [§3.13.6], key word ITER\_INTE\_PAS).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN (by DEBORST, key word ALGO\_C\_PLAN [§3.3.5]), INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 4*

*Significance: V1: plastic deformation cumulated in compression, V2: plastic deformation cumulated in traction, V3: maximum temperature attack at the point of Gauss considered, V4: indicator of plasticity.*

#### ***/"MAZARS"***

*Relation of elastic behavior fragile. It makes it possible to account for the softening of concrete and distinguishes the damage in traction and compression. Only one variable of scalar damage is used (cf [R7.01.08] for more details). Characteristics material are defined in operator DEF1\_MATERIAU [U4.43.01] under the key words MAZARS and ELAS (\_FO). In the event of thermal loading, the coefficients materials depend on the maximum temperature reached at the point of Gauss considered. Moreover thermal dilation presumedly linear does not contribute to the evolution of the damage.*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 3*

*Significance: V1: value of the damage, V2: indicator of damage (0 so not damaged, 1 if damaged), V3: maximum temperature attack at the point of Gauss considered.*

*Supported nonlocal modeling (see [§ 3.3.1.3]): GRAD\_EPSI.*

*/“LABORD\_ID”*

*Unidimensional relation of behavior of unilateral damage dedicated to the concrete, adapted to the cases of monotonous loadings (static) and cyclic (statics and dynamics without effect speed). It makes it possible to describe the behavior generated by the creation of microscopic cracks*

*(lowering of the stiffnesses) and bound operation, during cycles, with their refermeture (unilaterality). Two variables of damage are used (one in traction, the other in compression), the anelastic deformations related to the damage are taken into account and the opening and the refermeture of the cracks are managed by a function of progressive restoration*

*stiffness with the refermeture (cf [R7.01.07] for more details). Characteristics of material are defined in operator DEF1\_MATERIAU [U4.43.01] under the key words LABORD\_ID and ELAS.*

*Supported modeling: PMF*

*A number of internal variables: 5*

## **/"GRILLE\_PINTO\_MEN"**

Elastoplastic relation of isothermal behavior uniaxial of Pinto\_Menegotto for modeling of the reinforcements of the concrete reinforced under cyclic loading. Data necessary field material are provided in operator DEFI\_MATERIAU [U4.43.01], under the word key PINTO\_MENEGOTTO (cf for more detail the document [R5.03.09]).

Supported modelings: ROAST

A number of internal variables: 16

Significance: cf the document [R5.03.09]

## **/"PINTO\_MENEGOTTO"**

Relation of isothermal behavior uniaxial elastoplastic modelling the answer of steel reinforcements in the concrete reinforced under cyclic loading. Data necessary of field material are provided in operator DEFI\_MATERIAU [U4.43.01], under the word key PINTO\_MENEGOTTO (cf for more detail the document [R5.03.09]).

Supported modelings: BAR

A number of internal variables: 8

Significance: cf the document [R5.03.09]

## **/GLRC**

Elastoplastic model of reinforced concrete plate expressed in aggregate variables (efforts generalized deformations), with possible influence of the membrane effort on the limits of elasticity in inflection.

Supported modelings: DKTG

A number of internal variables: 7

**/“CORR\_ACIER”**

*Elastoplastic model endommageable for which the plastic deformation with rupture depends rate of corrosion.*

*Modelings: 3D, D\_PLAN, AXIS, BAR, PMF*

*3 internal variables*

*V1: cumulated plastic deformation*

*V2: coefficient of damage*

*V3: indicator of plasticity*

**/“JOINT\_BA”**

*Local relation of behavior in 2D describing the phenomenon of the steel-concrete connection for reinforced concrete structures. It makes it possible to account for the influence of the connection in redistribution of the constraints in the body of the concrete as well as the prediction of the cracks and them*

*spacing. Available for loadings into monotonous and cyclic, it takes into account effects of the friction of the cracks, and containment. Only one variable of damage scalar is used (cf [R7.01.21] for more details). The characteristics of material are defined in operator `DEFI_MATERIAU` [U4.43.01] under key words `JOINT_BA` and `ELAS`.*

*Supported modelings: `PLAN_FISSURE` and `AXIS_FISSURE`.*

*A number of internal variables: 6*

*Significance: V1: value of the damage in the normal direction, V2: value of the damage in the tangential direction, V3: scalar variable of isotropic work hardening for the damage in mode 1, V4: scalar variable of isotropic work hardening for the damage in mode 2, V5: deformation of slip cumulated by friction of cracks, V6: value of kinematic work hardening by friction of the cracks.*

### ***/"GRANGER\_FP"***

*Relation of behavior for the modeling of the clean creep of the concrete. Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key word GRANGER\_FP (cf [R7.01.01] for more details).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 55*

*Significance: Cf [R7.01.01]*

### ***/"GRANGER\_FP\_V"***

*Relation of behavior for the modeling of the clean creep of the concrete with taking into account phenomenon of ageing. The data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key word V\_GRANGER\_FP (cf [R7.01.01] for more details).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE and COQUE1D.*

*A number of internal variables: 55*

*Significance: Cf [R7.01.01]*

### ***/"GRANGER\_FP\_INDT"***

*Identical to GRANGER\_FP\_V but treating only one isothermal behavior.*

### ***/"UMLV\_FP"***

*Relation of behavior for the modeling of the clean creep of the concrete with taking into account distinction between voluminal creep and creep deviatoric in order to account for phenomena in the cases of multiaxial creeps. Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key word BETON\_UMLV\_FP (Cf [R7.01.06] for more details).*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE, BAR and COQUE1D.*

**/“BAZANT\_FD”**

*Relation of behavior for the modeling of the creep of dessiccation of the concrete. This phenomenon occurs in the long-term concrete under the simultaneous effect of drying and a loading mechanics. The data necessary of the field material are provided in the operator **DEFI\_MATERIAU** [U4.43.01], under key words **BAZANT\_FD** and **ELAS\_FO** (cf [R7.01.05] for more details). Under **ELAS\_FO**, it is imperative to inform key word **FONC\_DESORP**.*

*Supported modelings: 3D, **D\_PLAN**, **AXIS**, **C\_PLAN** (by **DEBORST**, key word **ALGO\_C\_PLAN** [§3.3.6]), **INCO**, **HULL**, **PIPE**, **BARS** and **COQUE1D**.*

*A number of internal variables: 1*

*Significance: **V1**: value of the hygroscoopy*

**/“KIT\_DDI”**

*Allows to add two terms with anelastic deformations defined by certain laws of already existing behavior in **COMP\_INCR** (cf [R5.03.60] for more details). One can to assemble a model of creep of concrete **GRANGER\_FP** or **GRANGER\_FP\_V** with either **ELAS**, or **BETON\_DOUBLE\_DP**, either **VMIS\_ISOT\_TRAC**, or **VMIS\_ISOT\_LINE**, or **ROUSS\_PR** or **CHABOCHE**. The two models to be associated are to be specified in **RELATION\_KIT** [§3.3.2]. data necessary of the field material are provided in operator **DEFI\_MATERIAU** [U4.43.01], under key words **ELAS** (**\_FO**) (the **two laws must have the same module of YOUNG**) and those corresponding to the two selected models.*

*The internal variables of each law are cumulated in the table of the internal variables, and restored law by law. Under the assumption that creep is a phenomenon which evolves/moves more slowly*

*that plasticity, one compares the tangent matrix of the complete model to that of plasticity. It choice will thus require to adapt the increments of calculation to times characteristic of phenomena modelled in order not to handicap calculation in term of iteration count.*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, INCO, HULL, PIPE, BAR and COQUE1D.*

*Example:*

```
STAT_NON_LINE = (
COMP_INCR = _F (
RELATION
= "KIT_DDI"
RELATION_KIT = ("GRANGER_FP", "BETON_DOUBLE_DP"))
```

*In this case, local parameters of convergence (RESI\_INTE\_RELA and ITER\_INTE\_MAXI under the key word CONVERGENCE) are the same ones for the integration of the two models.*

### ***3.1.1.10 Behavior for the porous environments (modeling thermo-hydro-mechanics)***

*For more details on modelings thermo-hydro-mechanics and the models of behavior, one will be able to consult the documents [R7.01.10] and [R7.01.11].*

*Relations make it possible to solve simultaneously from two to four equations of balance. The equations considered depend on suffix with the following rule:*

- M indicates the mechanical equilibrium equation,*
- T indicates the thermal equilibrium equation,*
- H indicates a hydraulic equilibrium equation.*
- V indicates the presence of a phase in form vapor (in addition to the liquid)*

*The associated problems thermo-hydro-mechanics are dealt with in a completely coupled way. Only one letter H means that the porous environment is saturated (only one variable of pressure p), by example either of gas, or of liquid, or of a liquid mixture/gas (of which the pressure of gas is constant).*

*Two letters H mean that the porous environment is not saturated (two variables of pressure p), by example a liquid mixture/vapor/gas.*

*The presence of two letters HV means that the porous environment is saturated by a component (with practical of water), but that this component can be in liquid form or vapor. There is not whereas one*

*Instruction manual*

*U4.5- booklet: Method of resolution*

**HT-62/06/004/A**

**33/46**

*conservation equation of this component, therefore only one degree of freedom pressure, but there is a flow liquid and a flow vapor.*

*For each modelled phenomenon (thermal and/or mechanical and/or hydraulic), one must specify in RELATION\_KIT [§ 3.3.2.3]:*

- the mechanical model of behavior of the skeleton,*
- the behavior of the liquids/gas,*
- the thermal behavior.*

*Moreover, in all the cases, one must imperatively inform:*

- HYDR\_UTIL (if the mechanical behavior is not endommageable, i.e if one does not use “MAZARS” or “ENDO\_ISOT\_BETON”) or HYDR\_ENDO (if one uses “MAZARS” or “ENDO\_ISOT\_BETON”) under RELATION\_KIT (this key word makes it possible to inform the curve of saturation and its derivative according to the capillary pressure as well as the relative permeability and its derivative according to saturation)*
- THM\_INIT in DEFI\_MATERIAU.*

**Example:**

**COMP\_INCR**

**=\_F (**  
**RELATION**

**=**  
**“KIT\_THM”,**  
**RELATION\_KIT**

**= (“LIQU\_SATU”, “CJS”, “HYDR\_UTIL”))**

*In this example, one deals with in a coupled way a problem thermo-hydro-mechanics for a medium porous saturated, LIQU\_SATU like behavior of the liquid, CJS like mechanical behavior.*

**Caution:**

*According to chosen, all the behaviors are not licit (for example if one chosen porous environments unsaturated, one cannot affect a behavior of the gas type perfect). [§ 3.3.2.3] summarizes all the possible combinations.*

**/“KIT\_HM”**

*Modeling of the coupling of the mechanical and hydrous phenomena for porous environments saturated. It is necessary to specify in RELATION\_KIT the mechanical behavior of the skeleton, it behavior of the liquid or gas or liquid mixture/gas (constant pressure of gas) and HYDR\_UTIL.*

**Supported modeling: THM**

**/“KIT\_THM”**

*Modeling of the coupling of the mechanical, thermal and hydrous phenomena for saturated mediums. It is necessary to specify in RELATION\_KIT the mechanical behavior of the skeleton, it thermal behavior, the behavior of the liquid or gas or liquid mixture/gas (pressure of gas constant) and HYDR\_UTIL.*

**Supported modeling: D\_PLAN\_THM, D\_PLAN\_THMD, AXIS\_THM, AXIS\_THMD, 3D\_THM, 3D\_THMD**

**/“KIT\_HHM”**

*Modeling of the coupling of the mechanical and hydrous phenomena for porous environments not saturated. It is necessary to specify in RELATION\_KIT the mechanical behavior of the skeleton, it behavior of the liquid mixture and/or gas and/or vapor and HYDR\_UTIL.*

**Supported modelings: D\_PLAN\_HHM, D\_PLAN\_HHMD, AXIS\_HHM, AXIS\_HHMD, 3D\_HHM,**

### 3.1.3 Operand

**DEFORMATION under COMP\_INCR**

**DEFORMATION:**

/  
“SMALL”

*The deformations used in the relation of behavior are the deformations linearized:*

(U)  
ij  
=  
1/2 (iu  
J  
+ U J

,  
I,  
/

“PETIT\_REAC”

*The increments of deformations used for the relation of incremental behavior are linearized deformations of the increment of displacement in the reactualized geometry.*

*I.e. if X, U*

*, U  
the position, displacement indicate respectively and*

*the increment of displacement calculated with a given iteration of a material point:*

I  
U  
U

I  
J

$$ij =$$

$$+$$

$$2 ($$

$$X + U)$$

$$(X + U)$$

$$J$$

$$I$$

*Balance is thus solved on the current geometry but the behavior remains writes under the assumption of the small deformations.*

**Caution:**

*It is disadvised using this option with the elements of structure HULL, COQUE\_1D and LOUSE (a message of alarm appears in the file .mess).*

**Note:**

*One can use this option with modelings THM since rotations are small.*

**/“SIMO\_MIEHE”**

*All information on the gradient of the transformation  $F$  is taken into account, as well rotation that deformations:*

$$U$$

$$F$$

$$I$$

$$ij = I$$

$$J +$$

$$X J$$

*That makes it possible to carry out calculations in great plastic deformations, with the relations of behavior “ELAS”, “VMIS\_ISOT\_LINE”, “VMIS\_ISOT\_TRAC”, “ROUSSELIER” and all them behaviors, with isotropic work hardening only, associated a material undergoing of metallurgical phase shifts (relations META\_X\_IL\_XXX\_XXX and META\_X\_INL\_XXX\_XXX,), (cf [§ 3.3.1.7]).*

**Caution:**

*This option is valid only for modelings 3D, D\_PLAN, AXIS, 3D\_INCO,*

*AXIS\_INCO and PLAN\_INCO (not of constraint planes with method DEBORST).*

*For further information on the formulation of the great plastic deformations according to SIMO and MIEHE, one will be able to refer to [R5.03.21].*

*Instruction manual*

*U4.5- booklet: Method of resolution*

*HT-62/06/004/A*

---

**Code\_Aster** ®

Version

8.2

Titrate:

*Nonlinear behaviors*

Date

:

31/01/06

Author (S):

Key **J.M. PROIX**

:

U4.51.11-B1 Page:

42/46

*In great deformations of the type “SIMO\_MIEHE”, the tangent matrices are not symmetrical except for case (hyper) - elastic. To version 7.4, one proceeded to a systematic symmetrization of the matrix. Henceforth, it is the matrix not symmetrical which is provided. If it wishes it, the user can nevertheless ask to symmetrize under the key word SOLVEUR = \_F (SYME = “YES”). Caution: SYME = “YES” is not the defect. The resolutions will thus take a priori more time with this new version if have it does not do anything with regard to the command file. By against the nonsymmetrical tangent matrix a better convergence will allow.*

**/“GREEN”**

*Allows to treat great rotations and the small deformations for all the laws of behavior under COMP\_INCR provided with modelings 3D, D\_PLAN, AXIS and C\_PLAN. The deformations used in the relation of behavior are the deformations of GREEN-LAGRANGE:*

$E(U$

$) =$

$1/2 (U$

+  $U$

+  $U$

. $u$

$ij$

$I, J$

$JI,$

$K I,$

$K, J)$

**/“GREEN\_GR”**

*Allows to treat great rotations and the small deformations for all the laws of behavior under COMP\_INCR provided with modelings COQUE\_3D.*

*The deformations used in the relation of behavior are the deformations of*

**GREEN-LAGRANGE:**

$E (U$

) =

$1/2 (U$

+  $U$

+  $U$

. $u$

$ij$

$I, J$

$JI,$

$K I,$

$K, J)$

**Caution:**

*It is strongly disadvised using linear research (cf [§3.9]) with the option*

*GREEN\_GR (sometimes convergence is impossible and if one converges, calculation needs more iterations of Newton).*

**3.1.4 Operands ALL/GROUP\_MA/MESH/GROUP\_NO/NODE under COMP\_INCR**

/

**ALL**

:

**“YES”**

// **GROUP\_MA: lgrma**

/ **NET**

: **lma**

*The meshes specify on which the incremental relation of behavior is used.*

### **3.1.5 Operand**

**ALGO\_C\_PLAN**

**ALGO\_C\_PLAN**

:

**“ANALYTICAL”**

**[DEFECT]**

**“DEBORST”**

*The method of DEBORST makes it possible to add the condition of plane constraint to all the models of COMP\_INCR (for more detail to see Doc. [R5.03.03]). The assumption of the plane constraints is checked with convergence. One recommends to use and reactivate the tangent matrix enough often (all the one with three iterations) in the method of Newton (MATRIX = “TANGENT”*

**REAC\_ITER**

*= 1 to 3). Attention, in AFFE\_MODELE, always to put PHENOMENON =*

**“C\_PLAN”**.

### **Caution:**

*Method DEBORST is not usable with the option of deformation SIMO\_MIEHE.*

*Instruction manual*

*U4.5- booklet: Method of resolution*

*HT-62/06/004/A*

---

Author (S):

Key **J.M. PROIX**

:

U4.51.11-B1 Page:

43/46

### **3.1.6 Operand**

**ALGO\_ID**

**ALGO\_ID:**

**“ANALYTICAL”**

**[DEFECT]**

**“DEBORST”**

*The method of DEBORST described above was generalized with the case of the behaviors 1D (used by modelings BARS, GRID, GRILLE\_MEMBRANE, POU\_D\_EM, POU\_D\_T\_GM). This makes it possible to add the condition of uniaxial constraint to all the models of COMP\_INCR (for detail to see Doc. [R5.03.09] more). The assumption of the uniaxial constraints is checked with convergence. One recommends to rather often use and reactualize the tangent matrix (all the one with three iterations) in the method of Newton (MATRIX = “TANGENT” REAC\_ITER = 1 to 3).*

#### **Caution:**

*Method DEBORST is not usable with the option of deformation SIMO\_MIEHE.*

### **3.2 Word**

**key**

**COMP\_ELAS**

/

**COMP\_ELAS:**

*This key word factor gathers the relations of behavior connecting the deformations (compared to configuration of reference) and the constraints (elastic behavior). One can have in even obeying calculation certain parts of the structure with various incrémentaux behaviors (COMP\_INCR) and other parts obeying with various elastic behaviors (COMP\_ELAS).*

#### **Small dictionary of the modelings supported by the laws of behavior**

*Not to overload this document, we will invite thereafter:*

.

**Modeling 3D**

= *modelings 3D and 3D\_SI*

.

*Modeling D\_PLAN = modelings D\_PLAN and D\_PLAN\_SI*

.

*Modeling AXIS*

= *modelings AXIS and AXIS\_SI*

.

*Modeling C\_PLAN = modelings C\_PLAN and C\_PLAN\_SI*

### **3.2.1 Operand**

#### **RELATION under COMP\_ELAS**

##### **RELATION**

= /

**“ELAS”**

**[DEFECT]**

/

**“ELAS\_VMIS\_LINE”**

/

**“ELAS\_VMIS\_TRAC”**

/

**“ELAS\_POUTRE\_GR”**

/

**“CABLE”**

**/“ELAS”**

*“Linear” relation of elastic behavior, i.e. the relation between the deformations and the constraints considered is linear. The data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01], under key words ELAS or ELAS\_FO, ELAS\_ORTH or ELAS\_ORTH\_FO and ELAS\_ISTR or ELAS\_ISTR\_FO. It is the relation of behavior by defect for the elastic behaviors.*

*Supported modelings: 3D, D\_PLAN, AXIS, C\_PLAN, CABLE\_POULIE and COQUE\_3D (with DEFORMATION: “GREEN\_GR”).*

**/“ELAS\_VMIS\_LINE”**

*“Nonlinear” relation of elastic behavior (law of HENCKY) of Von Mises with linear isotropic work hardening. The data necessary of the field material are provided in operator DEFI\_MATERIAU [U4.43.01], under the key words VMIS\_ISOT\_LINE and ELAS (Cf [R7.02.03] for more details).*

*Supported modelings: 3D, D\_PLAN, AXIS and C\_PLAN.*

44/46

**/“ELAS\_VMIS\_TRAC”**

*“Nonlinear” relation of elastic behavior (law of HENCKY), of Von Mises with nonlinear isotropic work hardening. The data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key words VMIS\_ISOT\_TRAC and ELAS (Cf [R7.02.03] for more details).*

*Supported modelings: 3D, D\_PLAN, AXIS and C\_PLAN.*

**/“ELAS\_POUTRE\_GR”**

*Elastic relation of behavior for the beams in great displacements and large rotations (DEFORMATION: “GREEN\_GR” is obligatory). Data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under key word ELAS or ELAS\_FO (cf [R5.03.40] for more detail).*

*Supported modelings: POU\_D\_T\_GD*

**/“CABLE”**

*Elastic relation of behavior adapted to the cables (DEFORMATION: Obligatory “GREEN”):*

*the YOUNG modulus of the cable can be different in compression and traction (in particular it can be null in compression). The data necessary of the field material are provided in operator DEF1\_MATERIAU [U4.43.01], under the key word CABLE (cf [R3.08.02] for more details).*

*Supported modelings: CABLE*

### **3.2.2 Operand**

#### **DEFORMATION under COMP\_ELAS**

#### **DEFORMATION**

:

/

**“SMALL”**

**[DEFECT]**

*The deformations used in the relation of behavior are the linearized deformations:*

(U

ij

=

1/2 (iu

J

+ U J

,

I,)

**“GREEN”**

*The deformations used in the relation of behavior are the deformations of GREEN-LAGRANGE:*

E (U

) =

1/2 (U

+ U

+ U

.u

ij

I, J

*J I,  
K I,  
K, J)*

***/“GREEN\_GR”***

*Allows to treat the hulls and the beams in great displacements and great rotations (Cf. [R5.03.40] pour les poutres et [R3.07.05] pour les coques pour plus de détail). Pour les poutres, GREEN\_GR n'est disponible que pour le comportement `ELAS\_POUTRE\_GR`, pour les coques uniquement avec `ELAS`.*

***Attention :***

*Pour les coques (modélisation COQUE\_3D), il est fortement déconseillé d'utiliser la recherche linéaire (cf. [§3.9]) avec l'option GREEN\_GR (parfois la convergence est impossible et si on converge, le calcul a besoin de plus d'itérations de Newton).*

## ***Procedure IMPR\_STURM***

### ***1 Goal***

***To calculate the number of eigenvalues included/understood in an interval and to print out it. This procedure is***

***advised like checking a priori of the model and to define intervals of research containing a reasonable number of eigenvalues in order to optimize the computing time of the operators MODE\_ITER\_SIMULT or MODE\_ITER\_INV.***

***The execution of this procedure requires two factorizations LDLT.***

***: 3/6***

### ***3 Operands***

***3.1 Operands***  
***MATR\_A and MATR\_B***

***MATR\_A: With***  
***MATR\_B: B***

***With and B being names of the assembled matrices, the problem generalized with the eigenvalues studied is:***  
***(A B) v = 0***

***In the traditional case of dynamics, A is the matrix of rigidity and B the matrix of mass.***  
***2***  
***eigenvalue is then connected to the Eigen frequency F by the formula: = (***  
***2 F).***

***In the case of the theory of linear buckling, A is the matrix of rigidity and B the matrix of geometrical rigidity. The eigenvalue is called critical load.***

***This procedure allows, before carrying out the search for eigenvalues, to know it numbers in a band stipulated by the user.***

***Method of calculation:***

***One applies the property of the continuations of STURM and the theorem of SYLVESTER (cf [R5.01.01 §2.5 and §2.6]). If  $\mu$  is a given spectral shift, the appearing number of negative pivots during symmetrical factorization (by LDLT) of  $(A - \mu B)$  is equal to the number of values clean real lower than  $\mu$ .***

### ***3.2 Operand***

***TYPE\_RESU***

*TYPE\_RESU* = /  
 “DYNAMIC”  
 [DEFECT]

/“MODE\_FLAMB”

*This key word makes it possible to define the nature of the modal problem to treat: search for frequencies of vibration (traditional case of dynamics) or search for critical loads (case of the theory of linear buckling).*

***3.3 Operands******FREQ\_MIN and FREQ\_MAX***

*FREQ\_MIN = F min*

*FREQ\_MAX = F max*

*These key words must be used if TYPE\_RESU = “DYNAMIC”. They define the terminals lower and higher in Hertz of the frequency band in which one seeks it a number of Eigen frequencies. These two terminals are positive realities. One seeks then*

*2  
 the number of eigenvalues in the band [*

*,  
 min  
 max] with: = (*

*\*  
 2 f\*)*

*Action by defect:*

*If FREQ\_MIN misses then one the number of Eigen frequencies included/understood calculates enters 0. and F max.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

Procedure *IMPR\_STURM*

Date:

21/01/05

Author (S):

**E. BOYERE, O. BOITEAU** Key

:

*U4.52.01-H Page*

: 4/6

### **3.4 Operands**

#### ***CHAR\_CRIT\_MIN and CHAR\_CRIT\_MAX***

*CHAR\_CRIT\_MIN = min*

*CHAR\_CRIT\_MAX = max*

*These key words must be used if TYPE\_RESU = "MODE\_FLAMB". They define the terminals lower and higher of the band of critical loads in which one seeks the number clean critical loads. These two terminals are realities positive or negative. One seeks then the number of eigenvalues in the band [*

*,  
min  
max].*

### **3.5 Operands**

#### ***PREC\_SHIFT and NMAX\_ITER\_SHIFT***

*PREC\_SHIFT*

*=  
pshift*

*NMAX\_ITER\_SHIFT*

*=*

*nshift*

If  $F_{min}$  ( $min$ ) or  $F_{max}$  ( $max$ ) is detected as being eigenvalues or being located near eigenvalues (loss of more than eight decimals ( $ndeci$ ) at the time of factorization of the shifted matrix ( $A - B$ )), they are then modified:

$$\begin{aligned} & \cdot \\ F_{-} &= F_{min} \\ & - \\ & min \\ & min \times (1 - pshift) ( \\ & = \\ & min \\ & min \times (1 - pshift)) \\ & \cdot \\ F_{+} &= F_{max} \\ & + \\ & max \\ & max \times (1 + pshift) ( \\ & = \\ & max \\ & max \times (1 + pshift)) \end{aligned}$$

One then seeks the number of eigenvalues in the new interval  $[F_{-}, F_{+}]$

$min$   
 $max]$   
 $([-, +$   
 $min$   
 $max])$

One is not authorized more  $nshift$  modifications of the terminals of the interval.

**3.6 Operand*****SEUIL\_FREQ***

$SEUIL\_FREQ = F_{threshold}$

If  $F_{min}$   
 $F_{min}$   
 $min$  threshold and if  $F_{min}$  is detected like eigenvalue, then one seeks it a number of Eigen frequencies in the interval  $[- F_{min}, F_{min}]$   
 $F_{min}$

*threshold, max].*

*It is considered whereas  $F_{min}$  is associated a mode of rigid body. Modification of limit lower interval allows a priori to enter all the modes of body rigid.*

*In the case of the theory of linear buckling, one replaces  $F$  by and one defines:*

*= (  
2  
threshold  
2  $F_{threshold}$ )*

### **3.7 Operand**

***NPREC\_SOLVEUR***

*NPREC\_SOLVEUR* = *ndeci*

*ndeci* represents the number of decimals which one is authorized to lose during factorization shifted matrix (*A - B*).

### **3.8 Operand**

***UNIT***

*UNIT*

Number of the logical unit corresponding to the file of writing. By defect, it is worth 8, i.e. file *RESU*.

### **3 Operands**

#### **3.1 Operands**

**MATR\_A/MATR\_B/INFORMATION/METHOD/OPTION**

*They have the same significance as in order MODE\_ITER\_SIMULT [U4.52.03].*

#### **3.2 Word**

*key*

**CALC\_FREQ**

*Play the same part as in order MODE\_ITER\_SIMULT [U4.52.03], has the same key words interns with the same default values, except for the following key words.*

### **3.2.1 Operands**

#### **FREQ\_MIN/FREQ\_MAX/NB\_BLOC\_FREQ**

*Give the terminals  $f_{min}$  and  $f_{max}$  of the total interval of frequencies of calculation and the number of subintervals  $npart$ .*

*In this case, the  $i$ ème terminal ( $i=1, npart+1$ ) is  $F(I) = f_{min} + (i-1) * (f_{max}-f_{min}) / npart$ .*

*Each subinterval has as respective terminals  $F(I)$  and  $F(i+1)$ .*

### **3.2.2 Operand**

#### **FREQ**

*One awaits a list of at least 2 values of frequencies  $F(I)$ .*

*$npart$  is obtained by the number of terms of the list -1.*

*The terminals of the subintervals are  $F(I)$  and  $F(i+1)$  for  $I = 1$  with  $npart$ .*

### **3.3 Word**

*key*

#### **VERI\_MODE**

*The operands intern have the same significance as in the key word of the same name, in order **MODE\_ITER\_SIMULT** [U4.52.03].*

### **3.4 Word**

*key*

#### **NORM\_MODE**

*Is used to define the arguments for the standardization of the modes. All the modes are normalized even way. The arguments are the same ones as for order **NORM\_MODE** [U4.52.11]*

### **3.5 Word**

*key*

#### **FILTRE\_MODE**

*If it is present, is used to introduce the arguments of filtering of the modes inside the  $npart$  key words **FILTRE\_MODE** (1 event by subinterval) of order **EXTR\_MODE** [U4.52.12] producing the final result. All the modes are filtered with the same criterion.*

*If it misses, the call to order **EXTR\_MODE** produces the final result by concatenation without filtering of the clean modes calculated in each subinterval. There is then  $npart$  words key*

*FILTRE\_MODE* having for argument *TOUT\_ORDRE* = “YES”.

**3 Operands**

### 3.1 Principles

*This operator solves the problem generalized with the eigenvalues according to [R5.01.01]: To find  $(\lambda, X)$  such as  $Ax = \lambda Bx$ ,  $X \neq 0$ , where  $A$  and  $B$  are symmetrical matrices with coefficients realities. To model a damping hysteretic in the study of the free vibrations of a structure, matrix  $A$  can be complex [U2.06.03] [R5.05.04]. This type of problem corresponds, in mechanics, in particular with:*

*The study of the free vibrations of a not deadened and nonrevolving structure. For this structure, one seeks the smallest eigenvalues or those which are in one interval given to know if an exciting force can create a resonance. In this case, matrix  $A$  is the matrix of material rigidity, noted  $K$  (real or complex), \_éventuellement increased geometrical matrix of rigidity noted  $k_g$ , if the structure is précontrainte\_, and  $B$  is the matrix of mass or noted inertia  $M$ . the eigenvalues obtained are the squares of the pulsations associated with the sought frequencies. The system to be solved can be written:  $(K + \lambda B)$*

*where  $\lambda = \omega^2$*

*$F$  is the square of*

*$G) X = \{$*

*$MX$*

*$4$*

*$1 4$*

*$2 3$*

*$B$*

*With*

*pulsation,  $F$  the Eigen frequency and  $X$  the vector of associated clean displacement.*

*If  $K$  is complex, and  $F$  it are too.*

*The search for linear mode of buckling. Within the framework of the linearized theory, in supposing a priori that the phenomena of stability are suitably described by system of equations obtained by supposing the linear dependence of displacement by report/ratio at the level of critical load, the research of the mode of buckling  $X$  associated it level of critical load  $\mu = \lambda$ , brings back itself to a problem generalized to the eigenvalues form:  $(K + \mu B)$*

*=*

*=*

*with  $K$  stamps material rigidity and*

*$G) X$*

*$0$*

{  
**Kx**  
**K X**  
{G  
**With**  
**B**  
**Kg** stamps geometrical rigidity.

**Caution:**

*In the code, one treats only the eigenvalues of the generalized problem, them. For to obtain the true critical loads, the  $\mu$ , it is necessary to multiply them by 1.*

*This operator allows also the study of the **dynamic stability of an involved structure depreciation viscous (and/or quadratic) and gyroscopic effects**. That led to resolution of a modal problem of a nature higher, known as quadratic [R5.01.02]. One seeks then complex values and clean vectors by the method of Lanczos after having carried out a reduction linear of the problem.*

*The problem consists in finding ( $\lambda$ ,  $\mathbf{X}$ ) ( $\mathbf{C}$ ,  $\mathbf{C}$  NR) such as  $(2\mathbf{B} + \mathbf{C} + \mathbf{A}) \mathbf{X} = 0$  where typically, in linear mechanics,  $\mathbf{A} = \mathbf{K}$  will be the matrix of rigidity,  $\mathbf{B} = \mathbf{M}$  the matrix of mass and  $\mathbf{C}$  the matrix of damping. The matrices  $\mathbf{K}$ ,  $\mathbf{M}$  and  $\mathbf{C}$  are matrices with real coefficients. The eigenvalue complexes is connected to the Eigen frequency  $F$  and to the damping reduced by:  $\lambda = (2) \pm (2) 1 - 2$*

$F$   
 $I$   
 $F$

*$\mathbf{K}$  can be also complex to moreover simulate, one damping hysteretic [U2.06.03] [R5.05.04].*

*:*

*U4.52.03-G Page**: 7/16*

*When it is a question of determining some simple eigenvalues discriminated well or to refine some estimates, operator `MODE_ITER_INV`, is often clearly shown. On the other hand, for to capture a part significant of the spectrum, one A resorts to `MODE_ITER_SIMULT`, via the methods known as “of subspace”.*

*It is this class of method which will interest us here.*

*It consists in projecting advisedly the operator of work in order to obtain a modal problem standard of more reduced size and comprising a canonical matrix of form (tridiagonale or of Higher Hessenberg). It is on the latter that total modal solveurs will be able then to operate (algorithm **QR**, **QL** or Jacobi). They are in general very robust, but they provide all the spectrum of the treated operator and they are very expensive. From where the idea to fix quotas for their efforts on only one “projected” spectrum.*

*It is completely recommended besides to benefit from the strong points of the two classes from method by refining the clean vectors obtained by `MODE_ITER_SIMULT`, via `MODE_ITER_INV` (`OPTION=' PROCHE'`). That will make it possible to reduce the standard of the final residue (cf [§3.7.2]).*

**Note:**

*One strongly advises a preliminary reading of the reference materials [R5.01.01], [R5.01.02]. It gives to the user the properties and the limitations, theoretical and practical, modal methods approached while connecting these considerations, which can sometimes to appear a little éthérées, with a precise parameter setting of the options.*

**3.2 Operands****`MATR_A, _B, _C`**`MATR_A``= A`

`MATR_B``= B`

*Stamp assembly of concept [`matr_asse_*_R`] system to be solved.*

`MATR_C`

= C

Stamp assembly of concept [matr\_asse\_\*\_R] quadratic system to solve.

### 3.3 Word

key

**TYPE\_RESU**

**TYPE\_RESU = /“DYNAMIC”**  
**[DEFECT]**

**/“MODE\_FLAMB”**

*This key word makes it possible to define the nature of the modal problem to treat: search for frequencies of vibration (traditional case of dynamics with or without damping) or search for loads critical (case of the theory of linear buckling). According to this class of membership, them results are posted and stored differently in the structure of data:*

***In dynamics**, the frequencies are ordered by order ascending of the module of their variation with the shift (cf [§2.9], [§4.4] [R5.01.01]). It is the value of the variable of access NUM\_ORDRE of the structure of data. The other variable of access, NUM\_MODE, is equal to the true modal position in the spectrum of the eigenvalue (determined by the test of Sturm cf [§2.5], [§2.6] [R5.01.01]).*

***In buckling**, the eigenvalues are stored by order ascending algebraic. variables NUM\_ORDRE and NUM\_MODE take the same value equal to this order.*

### **3.4 Word**

**key**

#### **METHOD**

*Three methods of resolution are available for the problem to the eigenvalues*

*.*

*The method WILL GO (known as of Sorensen), makes it possible to treat the two types of problems generalized and quadratic. It is the method by defect and is based on:*

*-*

*obtaining a matrix of Hessenberg by using a factorization of the Arnoldi type*

*-*

*the calculation of the eigenvalues of this problem projected by a method QR*

*-*

*a certain number of restartings allowing to refine the sought eigenvalues by the user, the other eigenvalues necessary to the method being used as values auxiliaries.*

*.*

*The method of Lanczos, makes it possible to treat the two types of problems generalized and quadratic. It is based on:*

*-*

*obtaining a matrix tridiagonale projected via the method of Lanczos,*

*-*

*the resolution of the system tridiagonal reduced by a method QR,*

*.*

*The iterative method of Bathe and valid Wilson only for the generalized problem, is based on:*

*-*

*construction with each iteration of a projected generalized problem of smaller size,*

*-*

*the calculation of the eigenvalues of this problem projected by a method of Jacobi.*

#### **METHOD**

**=**

**/“SORENSEN” [DEFECT]**

*One uses the method of Sorensen (cf [§5] [R5.01.01]) to calculate the values and vectors clean of the generalized or quadratic problem. This option cannot be used for one quadratic problem.*

*/“TRI\_DIAG”*

*One uses the method of Lanczos (then method **QR** on the projected system) to calculate them values and clean vectors of the generalized or quadratic problem (cf [§4] [R5.01.01]).*

*/“JACOBI”*

*One uses the method of Bathe & Wilson (cf [§6] [R5.01.01]) (then method of Jacobi on system projected) to calculate the values and clean vectors of the generalized problem. This option cannot be used for a quadratic problem.*

### **3.5 Word**

**key**

**OPTION**

**OPTION =**

**/“MODE\_RIGIDE”**

**/**

**“WITHOUT”**

**[DEFECT]**

*Key word usable only with the method of Lanczos for a generalized modal problem. It allows to detect and calculate as a preliminary, by an algebraic method the modes of body of rigid (modes associated with a null eigenvalue) (cf [§5.5.4] [R5.01.01]). They are used by the continuation to calculate the other modes with the algorithm of Lanczos. They are provided to the user*

*only if they belong to the modes requested. If the modes of rigid body are calculated without to use this option, the eigenvalues calculated by the algorithm of Lanczos are not null but very close to zero.*

### **3.6 Word**

**key**

**CALC\_FREQ**

**CALC\_FREQ**

**=\_F (...**

*Key word factor for the definition of the parameters of calculation of the eigenvalues and their number.*

*Instruction manual*

### **3.6.1 Operand**

#### **OPTIONS**

*OPTION*

=

**“BAND”**

*One seeks all the eigenvalues in a given band. This band is defined by the argument of **FREQ**: (F F) or by that of*

*1*

*2*

***CHAR\_CRIT**: ( ).*

*1*

*2*

*This option is not usable with a quadratic modal problem.*

**“CENTER”**

*One seeks the **NMAX\_FREQ** the eigenvalues closest to frequency F (argument of key word **FREQ**: F) or closest to the critical load (argument of key word **CHAR\_CRIT**: ).*

**“PLUS\_PETITE”** *One seeks the **NMAX\_FREQ** smaller eigenvalues.*

**[DEFECT]**

See [§2.9] and [§4.4] [R5.01.01].

### **3.6.2 Operand APPROACH**

**APPROACH**

= /

“**REAL**”

[**DEFECT**]

/

“**IMAG**”

/

“**COMPLEX**”

*This key word defines the type of approach (real, imaginary or complex) for the choice of pseudo scalar product of the quadratic problem (cf [§5.5.2] [R5.01.02]). In general the default value (reality) is valid.*

*This operand does not have a direction that for the analysis of the free vibrations of a deadened structure (modes proper complexes; key word **MATR\_C** must be indicated). In buckling, that does not have any interest.*

### **3.6.3 Operand FREQ**

**FREQ** =  $l_f$

*List frequencies (can be used only if **TYPE\_RESU** = “**DYNAMIC**”): its use depends on the selected **OPTION**.*

**OPTION** = “**BAND**”

*One awaits two values (**F F**) which define the band*

*1*

*2*

*of research,*

**OPTION** = “**CENTER**”

*Only one value of frequency is awaited,*

*The values stipulated under this key word must be positive.*

### **3.6.4 Operand AMOR\_REDUIT**

**AMOR\_REDUIT** =  $l_a$

*Value of the reduced damping which makes it possible to define the eigenvalue complexes around which one seeks the eigenvalues closest. (can be used only if TYPE\_RESU = "DYNAMIC" and well informed MATR\_C).*

**OPTION = "CENTER"**

*One awaits only one value of reduced damping,*

*The value stipulated under this key word must be positive and lie between 0 and 1. In buckling, that no interest has.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

*31/01/05*

*Author (S):*

***E. BOYERE, O. BOITEAU** Key*

*:*

*U4.52.03-G Page*

*: 10/16*

### **3.6.5 Operand**

#### **CHAR\_CRIT**

$CHAR\_CRIT = l\_c$

*List critical loads (can be used only if TYPE\_RESU = "MODE\_FLAMB"): its use depends on the selected OPTION.*

**OPTION = "BAND"**

*One awaits two values () which define the band*

*1*

*2*

*of research,*

**OPTION = "CENTER"**

*One awaits only one value of critical load,*

*The values stipulated under this key word are positive or negative.*

### **3.6.6 Operand**

#### ***NMAX\_FREQ***

*NMAX\_FREQ*

= *nf*

( 10 )

**[DEFECT]**

*Numbers maximum eigenvalues to calculate.*

*This key word is ignored with the option “BANDAGES” because one calculates all the eigenvalues then contained in the stipulated band.*

*In the two cases, if *nf* is strictly higher than the number of “ddl active”, *nactif* (cf [§2.2] [R5.01.01]), then one forces it to take this value ceiling.*

### **3.6.7 Operand**

#### ***DIM\_SOUS\_ESPACE***

*DIM\_SOUS\_ESPACE*

= *of*

*COEF\_DIM\_ESPACE*

= *mse*

**EXCLUDE (“DIM\_SOUS\_ESPACE”, “COEF\_DIM\_ESPACE”)**

*If key word *DIM\_SOUS\_ESPACE* is not indicated or is initialized with a value strictly lower than the number of required frequencies *nf*, the operator calculates one automatically acceptable dimension for the subspace of projection (cf [§5.2] of this document and [§4.3], [§5.5.2], [§6.5.3], [§7.3.1] [R5.01.01]) with assistance *COEF\_DIM\_ESPACE*.*

*Thanks to given of this multiplicative factor, *mse*, one can project on a space whose size is proportional to the number of frequencies contained in the interval of study. In the encapsulation of *MODE\_ITER\_SIMULT*, *MACRO\_MODE\_MECA* [U4.52.02], one can thus optimize*

*the size of the subspaces which remains proportional to the number of required frequencies: subspaces rich in eigenvalues thus do not penalize poorest (in term of CPU).*

*One can however arbitrarily fix the size of this subspace, via the value of the catch by key word *DIM\_SOUS\_ESPACE* (which must be higher than *nf* to be taken into account).*

*In both cases, if the size of the subspace of projection *ndim* is strictly higher than number “active *ddl*”, *nactif* (cf [§2.2] [R5.01.01]), then one forces it to take this value ceiling.*

**Note:**

.  
*If one uses the method of Sorensen (IRAM) and that  $ndim - nf < 2$ , of the requirements numérico-data processing force to impose  $ndim = nf + 2$ .*

.  
*Into quadratic one works on a real problem of double size:  $2*nf, 2*ndim$ .*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

### **3.9 Operand**

**STOP\_FREQ\_VIDE**

*STOP\_FREQ\_VIDE =/*

**“YES”**

**[DEFECT]**

/

**“NOT”**

*“YES” calculation stops if no eigenvalue is detected in the band stipulated by the user: an exception (named *BandeFrequenceVide*) is emitted. It can be treated to continue the course of the study. One can find an example under the case *SDLL11a* test:*

*try:*

*MODE1=MODE\_ITER\_SIMULT (MATR\_A=K\_ASSE, MATR\_B=M\_ASSE,*

*CALC\_FREQ=\_F (*

*OPTION = “BAND”,*

*FREQ = (100. , 200. )))*

*except aster.BandeFrequenceVideError:*

*MODE1=MODE\_ITER\_SIMULT (MATR\_A=K\_ASSE, MATR\_B=M\_ASSE,  
CALC\_FREQ=\_F (  
OPTION = "BAND",  
FREQ = (200. , 3500. , )))*

*"NOT" calculation (emission only of one ALARM) does not stop if no eigenvalue is detected in the band stipulated by the user.*

*This key word is used in macro-order MACRO\_MODE\_MECA [U4.52.02] in order to allow the absence of eigenvalues in a band of research.*

### **3.10 Operand INFORMATION**

*INFORMATION*

*= /  
1*

**[DEFECT]**

*/ 2*

*Indicate the level of impression in the file MESSAGE.*

*1 :*

*Impression on the file "MESSAGE" of the eigenvalues, their modal position, of reduced damping, of the standard of error a posteriori and certain useful parameters to follow the course of calculation (cf [§5.2])*

*2 :*

*Impression rather reserved for the developers.*

### **3.11 Operand TITRATE**

*TITRATE = Ti*

*Titrate attached to the concept produced by this operator [U4.03.01].*

**4**

## ***Phase of checking***

*One checks according to options':*

*OPTION = "BAND"*

*the argument of key word **FREQ** or key word **CHAR\_CRIT** must provide **two** values exactly,*

*OPTION = "CENTER"*

*the argument of key word **FREQ** or key word **CHAR\_CRIT** must provide **only one** value exactly,*

*OPTION = "PLUS\_PETITE"*

*the argument of key word **FREQ** or key word **CHAR\_CRIT**, is ignored.*

*If the maximum precise details and numbers of iterations are unrealistic (for example precise details lower than the precision machine or of the negative iteration counts), calculation is not carried out.*

## ***5 Phase of execution***

### ***5.1 Checking***

***The matrices **A**, **B** (and **C**) arguments of key words **MATR\_A** and **MATR\_B** (and **MATR\_C**), must be coherent between them (i.e. to be based on the same classification and the same mode of***

*storage).*

## 5.2

### *Actions by defect*

*If key word DIM\_SOUS\_ESPACE is not indicated or is initialized with a value strictly lower than the number of required frequencies  $nf$  (operand NMAX\_FREQ), the operator calculates automatically an acceptable dimension for the subspace of projection via the formulas empirical (cf [§3.6.7]):*

**METHOD = "SORENSEN"**

*$ndim = \text{MIN} (\text{MAX} (2+nf, mse*nf), nactif)$  with  $mse = 2$  per defect.*

**METHOD = "TRI\_DIAG"**

*$ndim = \text{MIN} (\text{MAX} (7+nf, mse*nf), nactif)$  with  $mse = 4$  per defect.*

**METHOD = "JACOBI"**

*$ndim = \text{MIN} (\text{MAX} (7+nf, mse*nf), nactif)$  with  $mse = 2$  per defect.*

*where  $nactif$  of  $ddl$  active (i.e. the total number of  $ddl$  less the number of  $ddls$  is the number of LAGRANGE and less the number of linear relations which bind  $ddls$  between them, cf [§2.2] [R5.01.01])*

*and  $mse$  is the factor of proportionality fixed by COEF\_DIM\_ESPACE.*

*If one solves a quadratic problem with the eigenvalues, the dimension of the subspace is doubled.*

*The values of these various parameters are printed in the file MESSAGE.*

## 6

### *Modal parameters/Standard of the modes/modal Position*

*At exit of this operator, the real or complex clean modes are standardized with largest components which is not a multiplier of LAGRANGE. To choose another standard, it is necessary to use order NORM\_MODE [U4.52.11].*

*In the case of a dynamic calculation, the structure of data mode\_meca\_\*, contains, in addition to frequencies of vibration and the associated modal deformations, the modal parameters (mass generalized, generalized stiffness, factor of participation, mass effective). One will find the definition of these parameters in [R5.01.03].*

*In the case of a linear calculation of buckling, the structure of data mode\_flamb, only contains critical loads and associated deformations.*

*In the case of a dynamic calculation, the modal position of the modes corresponds to the position of the mode*

*in the whole of the spectrum defined by the initial matrices.*

*In the case of a linear calculation of buckling, the modal positions of the critical loads are allotted of 1 to nf (nf being the number of calculated critical loads) by classifying the loads critical by order ascending algebraic. All the modal positions are thus positive.*

*Instruction manual*

*: 16/16*

*7*

*Impression of the results*

*To post the modal parameters associated with each mode and the co-ordinates with the modes, it is necessary*

*to use operator IMPR\_RESU [U4.91.01] in the following way:*

*· Affichage of the modal parameters only in the form of table:*

*IMPR\_RESU*

*(*

*RESU*

*=*

*\_F (*

*RESULT = mode,*

*TOUT\_PARA*

*=*

**“YES”,  
TOUT\_CHAM**

=

**“NOT”))**

;

*· Affichage of the modal parameters and the clean vectors:*

**IMPR\_RESU**

**(RESU =\_F (RESULT = mode,**

**TOUT\_PARA**

=

**“YES”,**

**TOUT\_CHAM**

=

**“YES”))**

;

8

*Sorting of modes/Characterization of mode\_meca\_\**

*For example, at the time of seismic requests in modal analysis, the modal base used must contain the modes which have an important unit effective mass in the direction of the seism.*

*Order EXTR\_MODE [U4.52.12] makes it possible to extract in a structure of data of the type mode\_meca\_\* of the modes which check a certain criterion and of concaténer several structures of data of the mode\_meca\_\* type.*

*An macro-order, allowing to connect orders MODE\_ITER\_SIMULT, NORM\_MODE and EXTR\_MODE was created: MACRO\_MODE\_MECA [U4.52.02].*

## **9 Examples**

### **3 Operands**

#### **3.1 Principles**

**This operator solves the problem generalized with the eigenvalues according to [R5.01.01]: To find  $(, X)$  such as  $Ax = Bx, X \neq 0$ , where  $A$  and  $B$  are symmetrical matrices with coefficients realities. This type of problem corresponds, in mechanics, in particular with:**

**The study of the free vibrations of a not deadened and nonrevolving structure. For this structure, one seeks the smallest eigenvalues or those which are in one interval given to know if an exciting force can create a resonance. In this case, matrix  $A$  is the matrix of material rigidity, noted  $K$ , (possibly increased stamp geometrical rigidity noted  $k_g$ , if the structure is prestressed) and  $B$  is the matrix of mass or noted inertia  $M$ . the eigenvalues obtained are the squares of the pulsations associated the sought frequencies.**

**The system to be solved can be written:  $(K + K$**

**where  $\omega = (\omega)^2$**

**$\omega^2 F$  is the square of**

**$G) X = \{$**

**$MX$**

**4**

**1 4**

**2 3**

**B****With**

**pulsation,  $F$  the Eigen frequency and  $X$  the vector of associated clean displacement.**

**The search for linear mode of buckling.** Within the framework of the linearized theory, in supposing a priori that the phenomena of stability are suitably described by system of equations obtained by supposing the linear dependence of displacement by report/ratio at the level of critical load, the research of the mode of buckling  $X$  associated it level of critical load  $\mu = -$ , brings back itself to a problem generalized to the eigenvalues form:  $(\mathbf{K} + \mu \mathbf{K}$

$=$   
 $=$   
 with  $\mathbf{K}$  stamps material rigidity and

 $G) X$  $0$ 

{

 $\mathbf{K}x$  $\mathbf{K} X$ { $G$ **With****B**

**$\mathbf{K}g$  stamps geometrical rigidity.**

**Caution:**

In the code, one treats only the eigenvalues of the generalized problem, them. For to obtain the true critical loads, the  $\mu$ , it is necessary to multiply them by 1.

This operator allows also the study of the **dynamic stability of an involved structure gyroscopic depreciation and effects**. That led to the resolution of a modal problem of a nature higher, known as quadratic [R5.01.02]. Clean values and vectors then are sought complexes by the method of Lanczos after having carried out a linear reduction of the problem.

The problem consists in finding  $(, X) (C, C NR)$  such as  $(2B + C + A) X = 0$  where typically, in linear mechanics,  $A$  will be the matrix of rigidity,  $B$  the matrix of mass and  $C$  the matrix of damping. The matrices  $A$ ,  $B$  and  $C$  are matrices with coefficients realities. The eigenvalue complexes is connected to the Eigen frequency  $F$  and damping reduced by:  $= (2) \pm (2) 1 - 2$

 $F$  $I$  $F$

### ***Table 3.1-1: Summary of the modal methods of Code\_Aster***

*When it is a question of determining some simple eigenvalues discriminated well or to refine some estimates, operator *MODE\_ITER\_INV*, is often clearly shown. On the other hand, for to capture a part significant of the spectrum, one A resorts to *MODE\_ITER\_SIMULT*, via the methods*

known as “of subspace”.

*It is the first class of method which will interest us here.*

*It consists in coupling a heuristic phase of localization of the eigenvalues (determination of an approximate value of each eigenvalue contained in an interval given by one technique of bisection, refined or not, by a method of the secant, in generalized, or by a method of Muller into quadratic), with a phase of iterations opposite itself (accelerated by a quotient of Rayleigh or not), which will improve these estimates all in exhuming the associated clean vectors.*

*: 6/14*

***It is completely recommended besides to benefit from the strong points of the two classes from method by refining the clean vectors obtained by **MODE\_ITER\_SIMULT**, via **MODE\_ITER\_INV** (**OPTION=' PROCHE'**). That will make it possible to reduce the standard of the final residue (cf [§3.6.2]).***

**Note:**

*One strongly advises a preliminary reading of the reference materials [R5.01.01] [R5.01.02]. It gives to the user the properties and the limitations, theoretical and practical, of modal methods approached while connecting these considerations, which can sometimes appear one little éthérées, with a precise parameter setting of the options.*

**3.2 Operands**

***MATR\_A, \_B, \_C***

*MATR\_A*

= A

*Stamp assembly of the type [matr\_asse\_\*\_R] system generalized or quadratic with to solve.*

*MATR\_B*

= B

*Stamp assembly of the type [matr\_asse\_\*\_R] system generalized or quadratic with to solve.*

*MATR\_C*

= C

*Stamp assembly of the type [matr\_asse\_\*\_R] quadratic system to solve.*

### **3.3 Word**

**key**

**TYPE\_RESU**

*TYPE\_RESU =/“DYNAMIC”*

**[DEFECT]**

*/“MODE\_FLAMB”*

*This key word makes it possible to define the nature of the modal problem to treat: search for frequencies of*

*vibration (traditional case of dynamics with or without damping) or search for loads critical (case of the theory of linear buckling). According to this class of membership, them results are posted and stored differently in the structure of data:*

.

***In dynamics**, the frequencies are ordered by order ascending of the module of their variation with the shift (cf [§2.9] [§4.4] [R5.01.01]). It is the value of the variable of access NUM\_ORDRE of the structure of data. The other variable of access, NUME\_MODE, is equal to the true modal position in the spectrum of the eigenvalue (determined by the test of Sturm cf [§2.5] [§2.6] [R5.01.01]).*

.

***In buckling**, the eigenvalues are stored by order ascending algebraic.*

*variables NUM\_ORDRE and NUM\_MODE take the same value equal to this order.*

### **3.4 Word**

*key*

***CALC\_FREQ***

***CALC\_FREQ***

***=\_F (...***

*Key word factor for the definition of the parameters of the first phase of calculation (localization of eigenvalues).*

*For the generalized problem, the localization of the eigenvalues is generally carried out by one dichotomic separation of the frequencies (for the options "ADJUSTS" and "SEPARATE"), followed of one*

*method of the secant (for the option: "ADJUSTS").*

*For the quadratic problem, this localization is carried out by a resolution of the problem not deadened (generalized problem) followed by a method of Muller (for the option: "ADJUSTS").*

### **3.4.1 Operand**

#### **OPTION**

*OPTION*

=

“NEAR”

*One seeks the mode to which the eigenvalue is closest to a given value. This value is indicated by:*

.  
*the argument *lfreq* of key word *FREQ* for a generalized problem of dynamic type (*TYPE\_RESU* = “DYNAMIC”).*

.  
*the argument *lcharc* of key word *CHAR\_CRIT* for a generalized problem of type linear buckling (*TYPE\_RESU* = “MODE\_FLAMB”).*

.  
*the arguments *lfreq* and *lamor* of key word *FREQ* and *AMOR\_REDUIT* for a problem quadratic of dynamic type (*TYPE\_RESU* = “DYNAMIC”).*

*There is as many research of modes than of terms in this list (or these lists). If one wish to calculate a multiple mode, one should not use this option because only one will be found only mode.*

“SEPARATE”

*One separates the eigenvalues by a method of bisection based on the criterion of Sturm. The terminals of the interval of research are:*

arguments of the list *lfreq* of key word *FREQ* for a generalized problem or quadratic of dynamic type (*TYPE\_RESU* = "DYNAMIC").

arguments of the list *lcharc* of key word *CHAR\_CRIT* for a problem generalized of linear buckling type (*TYPE\_RESU* = "MODE\_FLAMB").

## **"ADJUSTS"** **[DEFECT]**

After having separated the Eigen frequencies, as for the option "SEPARATE" one carries out additional iterations either by the method of the secant (generalized problem) or by method of Muller (quadratic problem) to obtain a better precision on the value clean.

### **3.4.2 Operand** **FREQ**

*FREQ* = *lfreq*

For a problem of search for eigenvalue of dynamic type (*TYPE\_RESU* = "DYNAMIC"), this key word corresponds to the list of the frequencies of which the use depends on the selected *OPTION*.

If "CLOSE" option: it is the list of the frequencies whose one seeks the mode nearest. The list has at least 1 element and is ordered by ascending order.

If option "SEPARATE" or "ADJUSTS": they are the terminals of the intervals of research  
*FREQ*: (*f1*, *f2*, ..., *fn-1*, *fn*)

One will seek to separate the frequencies in the intervals  
*[f1, f2]*, *[f2, f3]*, ..., *[fn-2, fn-1]*, *[fn-1, fn]*

The list has at least 2 elements. The frequencies are positive. It is checked that the frequencies are given in the ascending order.

### **3.4.3 Operand**

#### **AMOR\_REDUIT**

*AMOR\_REDUIT = lamor*

*For the quadratic problem of dynamic type ( $TYPE\_RESU = "DYNAMIC"$ ), and if the option  $CLOSE$  was chosen, one can initialize the method of the iterations opposite starting from a value clean initial complex. To build this complex value, the list of the arguments is used given under key words  $FREQ$  (list of frequencies) and  $AMOR\_REDUIT$  (list of depreciation). These two lists must have the same number of arguments.*

### **3.4.4 Operand**

#### **CHAR\_CRIT**

*CHAR\_CRIT = lcharc*

*For a problem of search for eigenvalue of buckling type of Euler ( $TYPE\_RESU = "MODE\_FLAMB"$ ), this key word corresponds to the list of the critical loads of which the use depends on the selected  $OPTION$ .*

*If " $CLOSE$ " option: it is the list of the critical loads whose one seeks the mode more near. The list has at least 1 element.*

*If option " $SEPARATE$ " and " $ADJUSTS$ ": they are the terminals of the intervals of research*

*CHAR\_CRIT: (1, 2, ..., n-1, N)*

*One will seek to separate the critical loads in the intervals*

*[1, 2], [2, 3].... [N2, n-1], [n-1, N]*

*The list has at least 2 elements. The critical loads are negative or positive. One checks that the critical loads are given in the ascending order.*

### **3.4.5 Operand**

#### **NMAX\_FREQ**

*NMAX\_FREQ = nf*

*( 0 )*

**[DEFECT]**

*Numbers maximum eigenvalues to calculate. This operand is ignored for the option “NEAR”.*

*For the other options, if the user does not inform this key word, all eigenvalues contained in the intervals specified by the user are calculated. If not, NMAX\_FREQ first eigenvalues, therefore lowest, are calculated*

### **3.7 Word**

**key**

**VERI\_MODE**

**VERI\_MODE = \_F (...**

**Key word factor for the definition of the parameters of the checking of the clean modes ([§2.9] [R5.01.01]).**

**Note:**

At the time of the first passages, it is strongly advised not to modify these parameters which the mysteries of the algorithm concern rather and which are initialized empirically with values standards.

Contrary to its alter-ego, *MODE\_ITER\_SIMULT*, this key word factor does not comprise key word of type *STURM* and *PREC\_SHIFT*. The phase of postprocessing and checking do not comprise indeed a test of Sturm which would be redundant with the first part heuristics. Methods of the type “power” being less robust than those of type “subspace”, the default value of the threshold *R* is less demanding (10-2 instead of 10-6).

### 3.7.1 Operand *STOP\_ERREUR*

*STOP\_ERREUR* =/  
“YES”

[DEFECT]  
/  
“NOT”

Allows to indicate to the operator if it must stop (“YES”) or continue (“NOT”) if one of the *THRESHOLD* criteria or *STURM* is not checked.  
By defect the concept of exit is not produced.

### 3.7.2 Operand *THRESHOLD*

-2  
*THRESHOLD*  
= *R* (1.10  
)  
[DEFECT]

Tolerance level for the standard of error relating of the mode to the top of which the mode is regarded as forgery.  
The standard of relative error of the mode is:

(A -)  
 $B \times 2$ , for 0 for the generalized problem and  
 $A \times 2$

$(2B + C - A) X^2,$   
 $Ax$   
*for the quadratic problem*  
2

### **3.8 Operand INFORMATION**

**INFORMATION**

= /  
1

**[DEFECT]**

/ 2

*Indicate the level of impression in the file MESSAGE.*

**1 :**  
*Impression on the file "MESSAGE" of the eigenvalues, their modal position, of reduced damping, of the standard of error a posteriori and certain useful parameters to follow the course of calculation.*

**2 :**  
*Impression rather reserved for the developers.*

### **3.9 Operand TITRATE**

**TITRATE =  $T_i$**

*Titrate attached to the concept produced by this operator [U4.03.01].*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster ®**

**Version**

**7.4**

**Titrate:**

## **Operator *MODE\_ITER\_INV***

**Date:**

**31/01/05**

**Author (S):**

**E. BOYERE, O. BOITEAU Key**

**:**

**U4.52.04-H Page**

**: 12/14**

### **4 Phase of execution**

#### **4.1 Checking**

**The matrices *A* and *B* (and *C*), arguments of key words *MATR\_A* and *MATR\_B* (and *MATR\_C*), must to be coherent between them (i.e. to be based on the same classification and the same mode of storage).**

**The operator checks that for the options “SEPARATE” and “ADJUSTS”, the list of the values of arguments of key word *FREQ* has, at least, two terms.**

**It checks also a certain coherence of the parameters of the various algorithms.**

#### **4.2 Execution**

**For the option “ADJUSTS”, if separation is not possible and that in a given interval there is more than one value of Eigen frequency, one does not apply the method of adjustment with this interval.**

**On the other hand, one will carry out during the calculation of the modes of the réorthogonalisations compared to modes preceding contents in the interval (this makes it possible to calculate modes associated with one multiple frequency).**

**For the option “SEPARATED”, having obtained an interval determining an Eigen frequency, one takes for the calculation of the mode medium of the interval. During the calculation of the mode, the value of the Eigen frequency is still refined. It is the result of the opposite iteration itself.**

## **5 Modal parameters/Standard of the modes/modal Position**

*At exit of this operator, the real or complex clean modes are standardized with largest components which is not a multiplier of Lagrange. To choose another standard, it is necessary to use order NORM\_MODE [U4.52.11].*

*In the case of a dynamic calculation, the structure of data mode\_meca\_\*, contains, in addition to frequencies of vibration and the associated modal deformations, the modal parameters (mass generalized, generalized stiffness, factor of participation, mass effective). One will find the definition of these parameters in [R5.01.03].*

*In the case of a linear calculation of buckling, the structure of data mode\_flamb, only contains critical loads and associated deformations.*

*In the case of a dynamic calculation, the modal position of the modes corresponds to the position of the mode*

*in the whole of the spectrum defined by the matrices A and B.*

*In the case of a linear calculation of buckling, the modal positions of the critical loads are allotted of 1 to nf (nf being the number of calculated critical loads) by classifying the loads critical by order ascending in absolute value. All the modal positions are thus positive.*

*For the CLOSE option, the modal positions are allotted of 1 to nf (nf being the number of values clean calculated), by taking the eigenvalues in the order of the list indicated under FREQ or CHAR\_CRIT.*

***Operator MODE\_ITER\_CYCL***

## **1 Goal**

*To calculate the clean modes of a structure with cyclic symmetry.*

*One calculates the generalized components of the clean modes of the whole structure, by a method of cyclic under-structuring, starting from the modal base of a sector of reference. The axis of symmetry is axis OZ. The modal base of sector must be of the TRADITIONAL type. The interfaces RIGHT-HAND SIDE, LEFT and possibly AXIS must be in the same way standard. The sides right and left are defined by the trigonometrical direction in plan OXY.*

*Product a structure of data of the mode\_cycl type.*

### **3 Operands**

#### **3.1 Operand**

***BASE\_MODAL***

***BASE\_MODAL = bamo***

***Name of the modal base of the sector built by *DEFI\_BASE\_MODAL* [U4.64.02].***

#### **3.2 Operand**

***NB\_MODE***

***NB\_MODE = nbmo***

***A number of modes clean of the sector to be used for cyclic calculation. By defect, if the key word does not appear, all the clean modes of the modal base are used.***

#### **3.3 Operand**

***NB\_SECTEUR***

***NB\_SECTEUR = nbsec***

***A number of basic sectors necessary to the construction of the total structure.***

#### **3.4 Word**

***key***

***CONNECTION***

## **CONNECTION**

*Key word factor for the definition of the connections between the sectors.*

### **3.4.1 Operands**

**LEFT RIGHT-HAND SIDE//AXIS**

*See [Figure 3.6-a].*

**RIGHT-HAND SIDE = “nom\_int”**

*Name of the right interface of the sector.*

**LEFT = “nom\_int”**

*Name of the left interface of the sector.*

**CENTER = “nom\_int”**

*Name of the interface of the axis of the sector.*

*They are points common to all the sectors.*

### **3.5 Word**

*key*

**CALCULATION**

**CALCULATION**

*Key word factor to define it mode of research of the clean modes.*

### **3.5.1 Operands**

**TOUT\_DIAM/NB\_DIAM**

**TOUT\_DIAM = “YES”**

*The modes associated with all the numbers of nodal diameters will be calculated.*

**NB\_DIAM = Li**

*List numbers of nodal diameters to calculate. By defect, all the numbers of possible nodal diameters are studied.*

*Instruction manual*

*3.5.2 Operand*

*OPTION*

*OPTION =*

*“PLUS\_PETITE”*

*: to calculate by a method of iteration reverses the clean modes corresponding to the smallest frequencies for each number of diameters requested.*

*“CENTER”:*

*to calculate the clean modes centered around a frequency requested by key word LIST\_FREQ.*

*“BAND”*

*:*

*to calculate the clean modes between two frequencies given by the user by key word LIST\_FREQ.*

*The Eigen frequencies are separated by dichotomy then the modes clean calculated by iterations opposite centered on the frequencies exits of the stage of separation.*

### 3.5.3 Operands

#### ***FREQ/NMAX\_FREQ***

***FREQ = lifreq***

*List frequencies of which the use depends on the selected option:*

***OPTION***

***=***

***“BAND”***

*One awaits 2 values (F F*

***1***

***2) which defines the band.***

***OPTION***

***=***

***“CENTER”***

*1 is awaited value which is the centre frequency of the interval.*

***OPTION***

***=***

***“PLUS\_PETITE”***

*One calculates the smallest Eigen frequencies of the structure. By defect, one calculates them 10 first. Key word FREQ then does not have a direction in this case, it does not have to be informed.*

***NMAX\_FREQ = nbfreq***

*A number of frequencies to be calculated for each number of nodal diameters asked. If it key word does not appear, one calculates as many frequencies, for each nodal diameter, that there is clean modes used in the modal base (key word NB\_MODE).*

### 3.5.4 Operands

#### ***PREC\_SEPARE/PREC\_AJUSTE/NMAX\_ITER***

***PREC\_SEPARE = pre\_sep***

***Precision of separation of the frequencies for option "BANDAGES".***

***PREC\_AJUSTE = pre\_ajus***

***Precision used for the calculation of the modes (all OPTIONS).***

***NMAX\_ITER = niter***

***Numbers maximum iterations opposite (all OPTIONS).***

***Formulation of the rules of standardization***

The various standards used as well as the definition of the various modal parameters are listed in the reference material [R5.01.03].

#### 4.1

##### **Real clean modes**

For the modes of the type *MODE\_MECA\_R* (real clean modes) the problem generalized with the values

$$\mathbf{K} - \mathbf{M} \mathbf{X} = (\mathbf{K} - 2$$

$\mathbf{F}$

$\mathbf{M})$

clean associated is: (

)

(

)

$$\mathbf{X} = 0$$

where  $\mathbf{K}$ ,  $\mathbf{M}$  are respectively the matrix of mass and the matrix of rigidity of the mechanical system.

For modelings "MECHANICS", one defines the components of the clean vector:

.

components of translation  $\mathbf{C}$

.

components of rotation  $\mathbf{uR}$

.

components of the multipliers of LAGRANGE

.

other components (pressure and fluid potential)  $p$

$\mathbf{F}$

One calls:

.

$\mathbf{uTR}$  component of translation and rotation,

.

$\mathbf{U}$  components other than multiplying of LAGRANGE.

what leads to

$\mathbf{C}$

***U***  
***U***  
***uR***  
***\* =***

*from where T I*  
*I*  
*2 and T*  
*I*  
*I*  
  
*I*  
*I*

*The standardization of the mode suitable for euclidian norm "EUCL" is obtained naturally by:*

\*

\*

 $U$  $U$  $U =$  $=$  $I$  $U$  $2$  $(U J)$  $J$ 

The standardization of the mode suitable for euclidian norm "EUCL\_TRAN" is:

\*

\*

 $T$  $U$  $U$  $U$  $I$  $=$  $=$  $T$  $U$  $2$  $(T$  $U J)$  $J$ 

## 4.2

### *Complex clean modes*

For the modes of the type *MODE\_MECA\_C* (complex clean modes) resulting from a resolution of one quadratic problem with the eigenvalues  $2 \mathbf{M} + \mathbf{C} + \mathbf{K} = \mathbf{0}$  where  $\mathbf{C}$  is the matrix of damping of the mechanical system, one normalizes the modes compared to the linearized problem associated:

$$\mathbf{0 M} - \mathbf{M 0}$$

+

= 0

**MR. C**

**0**

**K**

*The clean mode is normalized with the unit generalized mass ("MASS\_GENE"), if I satisfied:*

(

**0 M**

*T*

*T*

*I*

*I*

*I*)

= 1.

**MR. C**

*I*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

: 7/8

with unit generalized rigidity ("*RIGI\_GENE*"), if *I* satisfied:

$$\begin{aligned}
 & ( \\
 & - \mathbf{M} \mathbf{0} \\
 & T \\
 & T \\
 & I \\
 & I \\
 & I) \\
 & = I. \\
 & \mathbf{0} \\
 & \mathbf{K}
 \end{aligned}$$

*I*

For the other standards, the definitions are equivalent to those defined for the real modes, it is enough to replace the scalar product by the square product.

5

**Real modes examples**

For the modes of the type *mode\_meca* (real clean modes) resulting from a resolution of a problem generalized with the eigenvalues (**K - M**)

**X = 0:**

to normalize a clean vector  $X$  with unit generalized rigidity is equivalent so that  $X$  satisfies

$$\begin{aligned} \mathbf{x}^T \mathbf{K} \\ \mathbf{X} = \mathbf{1} \end{aligned}$$

Standardization with duplication of the concept *mode\_meca*:

$$\begin{aligned} mo\_2 \\ = \\ NORM\_MODE \\ (MODE \\ = \\ mo\_1, \\ NORME= \\ "RIGI\_GENE" \end{aligned}$$

);

to normalize a clean vector  $X$  with the unit generalized mass is equivalent so that  $X$  satisfies

$$\begin{aligned} \mathbf{x}^T \mathbf{M} \\ \mathbf{X} = \mathbf{1} \end{aligned}$$

Standardization "places from there" at the unit generalized mass:

$$\begin{aligned} Mo \\ = \\ NORM\_MODE \end{aligned}$$

(reuse = Mo,  
MODE

=

Mo,  
NORMALIZES

=

“MASS\_GENE”

);

3/6

### **3 Operands**

#### **3.1 Word**

**key**

**FILTRE\_MODE**

*One repeats this key word as many once as there are structures of data of the mode\_meca\_\* type or mode\_gene to be filtered and with concaténer.*

#### **3.2 Operand**

**MODE**

*Name of the structure of data mode\_meca\_\* or mode\_gene with sorting and concaténer with the others.*

#### **3.3**

**Filtering of the modes**

*To filter the modes, three possibilities are offered to the user.*

##### **3.3.1 Operands**

**NUME\_MODE/NUME\_ORDRE/TOUT\_ORDRE**

*List sequence numbers or modal positions of the modes which one wishes to preserve.*

##### **3.3.2 Operands**

**NUME\_MODE\_EXCLU**

*List modal positions of the modes which one wishes to remove.*

##### **3.3.3 Operands**

**FREQ\_MIN/FREQ\_MAX/PRECISION**

*One keeps all the modes which correspond to frequencies ranging between f\_min and f\_max to relative precision prec. One must have f\_min lower than f\_max.*

##### **3.3.4 Operand**

**CRIT\_EXTR**

***Choice of the parameter which is used as criterion for the filtering of the modes. If the criterion is “MASS\_EFFE\_UN” a mode will be retained as soon as one of its directional unit effective masses modal is higher than a threshold fixed by the user.***

***If the criterion is “MASS\_GENE” a mode will be retained as soon as the report/ratio of the mass generalized on summon generalized masses of the modes of the filtered structure is higher than a threshold fixed by the user.***

***Criterion “MASSE\_EFFE\_UN” has direction only for the structures of data of the type mode\_meca\_\****.

### ***3.3.5 Operands***

***THRESHOLD, SEUIL\_X, SEUIL\_Y, SEUIL\_Z***

***Limiting value of the criterion in lower part of which it is considered that one can filter the mode.***

***This value, in the case of the parameters currently taken into account, is a relative value adimensional.***

***One can apply the same threshold in all the directions (keyword THRESHOLD) or only differentiate according to directions X, Y or Z (SEUIL\_X, SEUIL\_Y, SEUIL\_Z)***

***3.4 Word***

*key*

## **IMPRESSION**

*This key word makes it possible to print a table of office plurality of certain parameters. These parameters can to be different from those selected in key words **FILTRE\_MODE**.*

### **3.4.1 Operand**

#### **OFFICE PLURALITY**

*Impression or not impression of the office pluralities of the modal parameter retained by **CRIT\_EXTR** for structure of data **resu\_mod** result.*

### **3.4.2 Operand**

#### **CRIT\_EXTR**

*Choice of the parameter of impression for which one carries out the operation of office plurality. If the criterion is*

*“**MASS\_EFFE\_UN**”, one cumulates separately the values of parameters '**MASS\_EFFE\_DX**, **MASS\_EFFE\_DY**, **MASSE\_EFFE\_DZ** of the extracted modes.*

*If the criterion is “**MASS\_GENE**” one cumulates the values of parameter **MASS\_GENE** of the extracted modes.*

### **3.5 Word**

*key*

#### **TITRATE**

*Titrate attached to the concept produced by this operator [U4.03.01].*

## **4 Execution**

*It is checked that the parameter for which one carries out filtering exists well in the structure of data **MOD** (parameters **MASS\_EFFE\_UN\_\*** are only indicated in the structure of data **MOD** if one used key word **MASS\_INER** of order **NORM\_MODE** when one renorme the modes). If this parameter is not indicated, one leaves in fatal error. On the other hand, for the key word **IMPRESSION**, if parameters **MASS\_EFFE\_UN\_\*** are not indicated, one emits only one alarm.*

*At exit, the concept produced **resu\_mod** should not be empty, if not one leaves in fatal error.*

*It is also checked that all the concepts **mode\_meca\_\*** or **mode\_gene** are in the same way standard and*

*that they come from the same initial problem (same matrices).*

*After having filtered the interesting modes, one checks that they have a whole a different modal position. In*

*the contrary case, one transmits a message of alarm. To remove these duplicated modes, it is necessary to re-use*

*order EXTR\_MODE and to activate operand NUME\_MODE\_EXCLU.*

*To date, it is not checked that the structures of data of the mode\_meca\_\* type correspond to one even standard.*

**Operator CALC\_AMOR\_MODAL**

**1 Goal**

**To create a list of modal depreciation calculated according to the rule of the RCC-G. Calculation is carried out in postprocessing of the modal calculation of a structure of the building type whose foundation raft rests on a ground modelled by springs.**

**The principle of calculation is based on weighting by the rates of potential energy (compared to the total energy) of the reduced depreciation affected by groups of meshes constitutive of the structure (in fact of the parameters of entry of the table of potential energy created by POST\_ELEM) and of depreciation radiated in the ground, by degree of freedom, functions of the frequency [bib1] [bib2].**

**The list created is usable thereafter in order DYNA\_TRAN\_MODAL [U4.53.21] behind key word LIST\_AMOR.**

### **3 Operands**

#### **3.1 Word**

**key**

**ENER\_SOL**

*This key word factor used only once is used to introduce the data necessary to calculation of potential energy in the ground per degree of freedom for all the frequencies of a concept of the type mode\_meca.*

#### **3.1.1 Operand**

**METHOD**

*This operand makes it possible to define the method of calculation of energy in the ground by frequency.*

*With value "DEPL", one calculates energy starting from the displacements realised on the nodes of*

*to erase for each mode:  $E =$*

*$K U^2 (Fr$*

*$I$*

*$I$*

*), where  $K$  represent 6 components  $KX, KY,$*

*$I$*

*$2$*

*$I$*

*$i=1,6$*

*$KZ, KRX, KRY$  and  $KRZ$  of the total rigidity within the competences of ground (cf [§3.1.3]).*

*With value “RIGI\_PARASOL”, one calculates energy starting from the efforts realised on the nodes of*  
*I*  
*F 2*  
*to erase for each mode: E*  
*I*  
*=*

*(Fr).*

*2*

*K*

*I*

*i=1,6*

*I*

*The efforts with the nodes with this method are given starting from the values of rigidity distributed with the nodes under the foundation raft as by option RIGI\_PARASOL of AFFE\_CARA\_ELEM [U4.42.01].*

### **3.1.2 Operand**

**MODE\_MECA**

*Allows to introduce the concept of the mode\_meca type containing the frequencies of calculation of energy potential.*

### **3.1.3 Operands**

**KX/KY/KZ/KRX/KRY/KRZ**

*The values of the components of the total rigidity within the competences of ground represent.*

*Intervene in the calculation of the terms K. U2, I*

*I*

*I*

*= 1, NCmp.*

*NCmp is the component count (3 or 6) determined by the presence or the absence of the operands KRX, KRY, KRZ used (if they are it) obligatorily together. NCmp and the number of ddls increased by the nodes of the foundation raft can be different.*

### **3.1.4 Operand**

**GROUP\_NO\_RADIER**

*This operand is related to value “DEPL” of the operand METHOD.*

*List groups of nodes constituting the foundation raft of the structure posed on the ground. One calculates thereafter the displacement realised in these nodes  $U$  of  $U_i$  components for each mode calculated of frequency  $Fr$  in order to be able to determine energy in the ground by ddl and frequency:*

*1  
2  
K. U (Fr  
1  
1  
)  
2*

*Instruction manual  
U4.5- booklet: Methods of resolution  
HT-66/05/004/A*

---

*Code\_Aster ®  
Version  
7.4*

*Titrate:  
Operator CALC\_AMOR\_MODAL*

*Date:  
08/02/05  
Author (S):  
G. DEVESA, Y. PONS Key  
:  
U4.52.13-F Page  
: 4/6*

*3.1.5 Operand  
GROUP\_MA\_RADIER*

*This operand is related to value “RIGI\_PARASOL” of the operand METHOD.*

*List groups of meshes constituting the foundation raft of the structure posed on the ground. Allows to calculate effort realised with the nodes of these meshes  $F$  of  $F_i$  components for each mode calculated of  
1  
2  
 $F$   
frequency  $Fr$  in order to determine energy in the ground by ddl and frequency:*

*I (Fr).*

*2 ki*

### **3.1.6 Operand**

**FONC\_GROUP/COEF\_GROUP/GROUP\_NO\_CENTRE/NOEUD\_CENTRE/  
COOR\_CENTRE**

*These operands are also related to value “RIGI\_PARASOL” of the operand METHOD.*

*These are the same ones as in option RIGI\_PARASOL of AFFE\_CARA\_ELEM [U4.42.01]. They allow*

*also to obtain the values of rigidity distributed with the nodes under the foundation raft being used to determine them*

*nodal efforts by mode then their average  $F$  of  $F_i$  component.*

*An operand chosen among FONC\_GROUP/COEF\_GROUP makes it possible to determine weightings,*

*real functions of the X-coordinate or, each group of meshes constitutive of the foundation raft.*

*formulas remain with the choice of the user. By defect, one considers that the function of distribution is*

*constant and unit, i.e. that each surface is affected same weight [bib2].*

*One thus needs as many terms in the corresponding list than in the list of the groups of meshes data by operand GROUP\_MA\_RADIER.*

*An operand chosen among GROUP\_NO\_CENTRE/NOEUD\_CENTRE/COOR\_CENTRE makes it possible to provide*

*that is to say the central node of the foundation raft by a group of nodes of only one name or by a single name of node,*

*that is to say directly its co-ordinates.*

### **3.2 Word**

*key*

**AMOR\_INTERNE**

*Used only once.*

*The contribution to the reduced damping of each mode is established starting from the distribution of potential energy in the structure for the mode considered. This distribution is obtained using*

*order POST\_ELEM [U4.81.22] starting from the concept of the mode\_meca type (cf [§3.1.1]) which produces*

*a table.*

*The parameters of entry of this table are names of groups of meshes, defined by the user according to the distributions of material damping in the structure.*

### **3.2.1 Operand**

#### ***ENER\_POT***

*Name of the table of potential energy produced by order POST\_ELEM [U4.81.22].*

### **3.2.2 Operand**

#### ***GROUP\_MA***

*The list of names of groups of meshes from which one will point in the table defined by ENER\_POT (cf [§3.2.1]).*

### **3.2.3 Operand**

#### ***AMOR\_REDUIT***

*The list of the actual values of material damping corresponding, term for term, with the list of names of groups of meshes defined by GROUP\_MA (cf [§3.2.2]).*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

*:*

*U4.52.13-F Page*

*: 5/6*

### **3.3 Word**

*key*

***AMOR\_SOL***

*Used only once.*

*It makes it possible to determine the contribution of geometrical damping due to the reflexion of the*

**waves**

**rubber bands. These directional values of damping are obtained while interpolating for each**

(  
 **$Im K ()$**   
**calculated Eigen frequency geometrical functions of damping**  
**(cf § [3.3.1]) where**  
 **$2 Re (K ())$**   
 **$K ()$**   
**is the complex impedance of the ground determined using one of software MISS3D, CLASSI or**  
**PARASOL:**

(  
 **$Im K ()$**   
 **$I$**   
 **$amor () =$**   
 **$I$**   
**,  $I$**

**$2 Re (K ())$**   
 **$I$**

### **3.3.1 Operand** **FONC\_AMOR\_GEO**

**Defines the list of functions of the frequency of geometrical depreciation, one by ddl (3 or 6).**

### **3.3.2 Operand** **AMOR\_REDUIT**

**Correction in the calculation of geometrical damping due to the reduced material damping of the ground.**

**Note:**

**The value of reduced damping is necessary only if the impedance of the ground is produced by PARASOL. If the impedance of the ground is produced by MISS3D, this value is not necessary that if the ground is homogeneous (see HOMOGENEOUS operand [§3.3.3]).**

### **3.3.3 Operand** **HOMOGENEOUS**

*If the ground is homogeneous (“YES”), one balances the calculation of damping in the ground (material more geometrical) by factor 0.5. Then if the impedance of the ground is produced by MISS3D, one must introduce for operand AMOR\_REDUIT (cf [§3.3.2]) the half-value of material damping tiny room of the ground.*

### **3.3.4 Operand THRESHOLD**

*Value defined in the RCC-G [bib1] (0.3 per defect) for the threshold beyond which one truncates possibly modal damping. This threshold operates after the possible preceding corrections.*

## 5 Example of use

The use of *CALC\_AMOR\_MODAL* requires the calculation of the clean modes of the structure on springs of ground in the form of a concept of the *mode\_meca* type and a concept of the type *tabl\_ener\_pot* of these modes calculated by means of order *POST\_ELEM* [U4.61.04].

The following example is extracted from test *SDLL109B*.

**# CALCULATION OF THE MODAL QUANTITIES -----**

```
MODE0=MODE_ITER_SIMULT (MATR_A=RIGIDITE,
MATR_B=MASSE,
CALC_FREQ=_F (OPTION = "PLUS_PETITE",
DIM_SOUS_ESPACE = 125,
NMAX_FREQ = 33))
```

```
MODE0=NORM_MODE (reuse=MODE0, MODE=MODE0, NORME=' TRAN_ROTA',
MASS_INER=MASSESTR)
```

```
EPOT=POST_ELEM (MODELE=STICKMOD,
RESULTAT=MODE0,
CHAM_MATER=CHAMPMAT, CARA_ELEM=CARA_ELE,
ENER_POT=_F (ALL = "YES",
GROUP_MA = ("POU_D_T", "MASSES", "LIAI_NOE", "LIAI_SOL"),)
)
```

```
#
FT=DEFI_FONCTION (NOM_PARA=' FREQ',
VALE= (0. , 0.0, 10. , 0.3, 30. , 1.5, 100. , 1.5,))
```

```
#
FR=DEFI_FONCTION (NOM_PARA=' FREQ',
VALE= (0. , 0.0, 10. , 0.05, 30. , 0.75, 100. , 0.75,))
```

```
L_AMOR=CALC_AMOR_MODAL (
ENER_SOL=_F (MODE_MECA = MODE0,
GROUP_NO_RADIER = "PI",
KX = 6.295E11, KY = 6.295E11, KZ = 6.864E11,

## ***Operator MODE\_STATIQUE***

### ***1 Goal***

***To calculate static modes for a displacement, a force or a unit acceleration imposed.***

***A static mode is the static deformation of an isostatic or hyperstatic structure to which one impose:***

***.  
in a ddl blocked (node - component) a unit imposed displacement,***

***.  
in a free ddl (node - component) a unit nodal force,***

***.  
in a ddl (node - component) a unit imposed acceleration,***

***.  
in a direction, a unit imposed acceleration.***

***The operator allows to calculate the whole of the static modes corresponding to several couples node - component. The matrix of rigidity must be assembled by using a whole of conditions with the limits sufficient kinematics so that all the solid modes of body are removed (operators AFFE\_CHAR\_MECA [U4.44.01] or AFFE\_CHAR\_CINE [U4.44.03]). It is possible of to ask that part of the static modes corresponding to these conditions kinematics.***

***The produced concept can be used to supplement a modal base of clean modes of vibration (operator DEFI\_BASE\_MODAL [U4.64.02] or DYNA\_ALEA\_MODAL [U4.53.22]) or to determine loadings necessary to the calculation of the movement of drive under a seismic excitation (operator CALC\_CHAR\_SEISME [U4.63.01]).***

***Product a concept of the mode\_stat\_depl type, mode\_stat\_acce or mode\_stat\_forc according to the selected option of calculation.***

**4 Phase  
of execution**

.

for option *MODE\_STAT* or *PSEUDO\_MODE* (on groups of nodes), the operator checks that the couple node - component is well a blocked ddl,

.

for option *FORCE\_NODALE*, the operator checks that the couple node - component is a ddl free,

.

for option *PSEUDO\_MODE* (on a direction), the operator normalizes the directing vector given under the key word *DIRECTION*,

.

the matrix of mass is necessary for the calculation of options *PSEUDO\_MODE*,

.

if a couple node - component appears more once, one makes calculation required only one only time.

***Operator DYNA\_NON\_LINE***

## ***1 Goal***

***To calculate the dynamic evolution of a structure whose material or geometry has a behavior nonlinear. They can be for example nonlinearities of material (plasticity or geometry (great displacements)) [R5.05.05]. The syntax of this order is very similar to that of operator STAT\_NON\_LINE [U4.51.03].***

***The dynamic evolution is studied starting from an initial state, configuration of reference, which can be produced by a quasi-static analysis (operator STAT\_NON\_LINE [U4.51.03]) or dynamics former (operator DYNA\_NON\_LINE).***

***The dynamic evolution can be studied in several successive work, by a continuation to be left from one moment already calculated, if a data base were defined in the profile of study of the user.***

***Product a concept of the evol\_noli type.***

### **3 Operands**

#### **3.1 Operands**

***MODEL/CHAM\_MATER/CARA\_ELEM/MODE\_STAT***

***MODEL = Mo***

*Name of the model whose elements are the subject of mechanical calculation.*

***CHAM\_MATER = chmat***

*Name of the affected material field on the model Mo.*

***CARA\_ELEM = carac***

*Name of the characteristics of the elements of hull, beam, bars, discrete cable, and elements affected on the model Mo, if necessary.*

***MODE\_STAT = modestat***

*Name of the static mode necessary in the case of a seismic calculation with excitations multi-supports [R4.05.01].*

#### **3.2 Word**

***key***

***EXCIT***

***EXCIT = \_F***

*This key word factor makes it possible to describe with each occurrence a load (requests and conditions with the limits), and possibly a multiplying coefficient and/or a type of load.*

### **3.2.1 Operands**

#### **CHARGE/FONC\_MULT**

*CHARGE =  $chi$*

*CH is the mechanical loading (possibly comprising the evolution of a field of temperature) specified with the  $i$ ème occurrence of EXCIT.*

*Only one load can comprise the evolution of a field of temperature, which will have previously be defined thanks to key word TEMP\_CALCULEE of the order AFFE\_CHAR\_MECA.*

*FONC\_MULT =  $f_i$*

*F is the multiplying function of the time of the loading specified with the  $i$ ème occurrence of EXCIT.*

*The loading and boundary conditions for N occurrences of the key word factor EXCIT are:*

$$\begin{aligned}
 &N \\
 &CH = F CH \\
 &I \\
 &I \\
 &I \\
 &= 1
 \end{aligned}$$

*For the conditions of DIRICHLET, of course, only the specified value is multiplied by F.*

*By defect:  $F = 1$ .*

*The field of temperature is not multiplied by F.*

### 3.2.2 Operand

#### **TYPE\_CHARGE**

 $TYPE\_CHARGE = tchi$ 

By defect, *tchi* is worth “*FIXE\_CSTE*”: that corresponds to a loading applied to initial geometry and not controlled. It can however be a function, and depend in particular time.

If *tchi* is worth “*FIXE\_PILO*”, the loading is always fixed (independent of the geometry) but will be controlled thanks to the key word *PILOTING* [§3.11].

The loads controllable must result from *AFFE\_CHAR\_MECA* or *AFFE\_CHAR\_MECA\_F* and not to be affected key word *FONC\_MULT*. One cannot to control the loadings of gravity, the centrifugal force, the forces of Laplace, them thermal loadings or of initial or anelastic deformations, and conditions of connection.

If *tch* is worth

*I*

“*SUIV*”, the loading is known as “*follower*”, i.e. it depends on the value unknown factors: for example, pressure, being a loading applying in the direction normal with a structure, depends on the geometry brought up to date of this one, and thus of displacements. A following loading is revalued with each iteration of the algorithm of resolution. A fixed loading is revalued only at each new moment, and only if *chi*

*depends on time (defined in AFFE\_CHAR\_MECA\_F and parameterized by the moment).*

*Currently the loadings which can be qualified “SUIV” are the loading of gravity for the element of CABLE\_POULIE, the pressure for modelings 3D, 3D\_SI, D\_PLAN, D\_PLAN\_SI, AXIS, AXIS\_SI, C\_PLAN, C\_PLAN\_SI and for all them modelings THM (3D\_HHM, 3D\_HM, 3D\_JOINT\_CT, 3D\_THH, 3D\_THHM, 3D\_THM, AXIS\_HHM, AXIS\_HM, AXIS\_THH, AXIS\_THHM, AXIS\_THM, D\_PLAN\_HHM, D\_PLAN\_HM, D\_PLAN\_THH, D\_PLAN\_THHM, D\_PLAN\_THM) and the centrifugal force into large displacements (key word ROTATION in AFFE\_CHAR\_MECA).*

*If tchi is worth “DIDI then” the conditions of DIRICHLET (imposed displacements, conditions linear) will apply to the increment of displacement as from the moment given under ETAT\_INIT/NUME\_DIDI (by defect the moment of resumption of calculation) and not on displacement total. For example for an imposed displacement (key word DDL\_IMPO of AFFE\_CHAR\_MECA) the condition will be form:  $U - U = D$*

*0  
where  $u_0$  is the displacement defined by  
NUME\_DIDI and not:  $U = D$ .*

### **3.2.3 Operands**

**MULT\_APPUI /ACCE /VITE /DEPL /DIRECTION /NOEUD /GROUP\_NO**

*In the case of an excitation multi-supports (MULT\_APPUI = “YES”), the other operands have exactly same significance as in the key word factor EXCIT of the operator DYNA\_TRAN\_MODAL [U4.53.21]. In this case, fields “DEPL”, “QUICKLY”, “ACCE” correspond respectively with displacements, speeds and accelerations of the relative movement compared to movement of drive multi-supports. New fields “DEPL\_ABSOLU”, “VITE\_ABSOLU”, “ACCE\_ABSOLU” are then created and respectively correspond at displacements, the speeds and accelerations of the absolute movement, summons movement of drive multi-supports and relative movement compared to this movement of drive multi-supports.*

### **3.3 Word**

**key**

**SOUS\_STRUC**

**SOUS\_STRUC**

*This key word factor makes it possible to specify which are the loadings to be used for static substructures which then form obligatorily part of the model. In its absence, them loadings on under structures are null.*

*These loadings are added to the loadings “finite elements” which can be applied to remain model.*

*Instruction manual*

13/22

### **3.3.1 Operand**

**CAS\_CHARGE**

*CAS\_CHARGE = nocas*

*nocas is the name of the loading case to be used. See operator MACR\_ELEM\_STAT [U4.62.01].*

### **3.3.2 Operands**

**ALL/MESH**

*/ALL = "YES"*

*This key word makes it possible to affect the loading nocas to all under structures of the model.*

*/*

*NET*

*=*

*l\_mail*

*This key word factor makes it possible to assign the loading nocas only to certain substructures.*

## **3.4 Word**

**key****COMP\_INCR**

/ COMP\_INCR =\_F

*This key word factor gathers the relations of behavior connecting of the rates of deformations to rates of constraints (incremental behavior). One can have in same calculation certain parts of the structure obeying with various incrémentaux behaviors (COMP\_INCR) and other parts obeying with various elastic behaviors (COMP\_ELAS). All the incremental relations of behavior supported by STAT\_NON\_LINE are available also in DYNA\_NON\_LINE, provided that the calculation of the matrix of mass elements concerned is envisaged. One will thus refer to the document [U4.51.11] for a description of the relations of behavior available (operand RELATION) thus that other operands of key word COMP\_INCR.*

**3.5 Word****key****COMP\_ELAS**/  
COMP\_ELAS =\_F

*This key word factor gathers the relations of behavior connecting the deformations (taken by report/ratio in an initial state of reference) and the constraints (elastic behavior). All them incremental relations of behavior supported by STAT\_NON\_LINE are available also in DYNA\_NON\_LINE, provided that the calculation of the matrix of mass of the elements concerned either envisaged. One will thus refer to the document [U4.51.11] for a description of relations of behavior available (operand RELATION) as well as other operands of key word COMP\_ELAS.*

**3.6 Word****key****ETAT\_INIT**

ETAT\_INIT =\_F

*Under this key word the initial conditions of the problem are defined. If key words EVOL\_NOLI, DEPL, and QUICKLY miss, one supposes that the initial state is with displacements, speeds and constraints null, and one calculates accelerations corresponding to the loading at the moment instini defined by operand INST. The other operands of key word ETAT\_INIT have the same one significance that in the document [U4.51.03].*

**3.7 Word****key**

## ***INCREMENT***

*INCREMENT =\_F*

*The list of the moments of calculation defines. The operands of the key word INCREMENT have the same one significance that in the document [U4.51.03].*

## ***3.8 Word***

*key*

***NEWTON***

*NEWTON*

*=\_F*

*Specify the characteristics of the method of resolution of the nonlinear incremental problem (method of NEWTON-RAPHSON). The operands of the key word NEWTON have the same significance that in the document [U4.51.03].*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

## ***3.9 Word***

*key*

***RECH\_LINEAIRE***

*RECH\_LINEAIRE =\_F*

*Linear research can make it possible to improve convergence of the method of Newton (Cf [R5.03.01] for more details).*

### **3.9.1 Operand**

#### ***RESI\_LINE\_RELA/ITER\_LINE\_MAXI***

*RESI\_LINE\_RELA =/  
1.E-1 [DEFECT]  
/  
reslin*

*ITER\_LINE\_MAXI  
=  
/  
3  
[DEFECT]  
/  
itelin*

*They are the parameters of linear research. The maximum iteration count is given itelin to be carried out and the precision reslin to reach to carry out the convergence of linear research.*

*It is not necessary to specify a precision nor an iteration count very high, practical showing that 2 or 3 iterations of linear research are sufficient. One can thus to be satisfied to ask 3 iterations with the precision by defect.*

### **3.9.2 Operand**

#### ***PAS\_MINI\_CRIT/ITER\_LINE\_CRIT***

*PAS\_MINI\_CRIT  
=  
/  
0.  
[DEFECT]*

*/*

*pmicri  
[R]*

*ITER\_LINE\_CRIT =/20*  
*[DEFECT]*

/

*itelic*  
*[I]*

*At the time of step of time when convergence is delicate, one can want to increase the number maximum of iterations of required linear. It is what the key words allow PAS\_MINI\_CRIT and ITER\_LINE\_CRIT. When the step of time (directly fixed by the user or consequence of cuttings of step of time) becomes lower than the value pmicri, the iteration count of linear search for research passes from itelin (informed by ITER\_LINE\_MAXI) with itelic (informed by ITER\_LINE\_MAXI).*

### **3.9.3 Operands**

***RHO\_MIN/RHO\_MAX/RHO\_EXCL***

*RHO\_MIN =/1.E-2*  
*[DEFECT]*

/

*rmin*

### **3.10 Operand**

**PARAM\_THETA**

*PARAM\_THETA*

=

/

1.

[DEFECT]

/

*theta*

*For modelings THM, the argument theta is the parameter of the theta-method used for to solve the evolutionary equations of thermics and hydraulics (cf [R5.03.60] for more details). Its value must lie between 0 (explicit method) and 1 (method completely implicit).*

*For the laws of behaviors ROUSS\_VISC, ASSE\_COMBU, ZIRC\_CYRA2 and ZIRC\_EPRI, the argument theta is used for integration of the law of behavior (for model ASSE\_COMBU, it is used to integrate the law of Lemaitre in 1D). It can take values 0.5 or 1.*

### **3.11 Word**

**key**

#### **PILOTING**

*PILOTING =\_F*

*When the intensity of part of the loading is not known a priori (loading known as of reference defined in AFFE\_CHAR\_MECA or AFFE\_CHAR\_MECA\_F with load of the type FIXE\_PILLO), the key word PILOTING makes it possible to control this loading via one node (or node groups) on which one can impose various modes of piloting (key word TYPE). The operands of the key word PILOTING have the same significance as in the document [U4.51.03]. However, this option also activates with DYNA\_NON\_LINE is to be used there with reserve owing to the fact that time has a physical and nonvirtual significance: it is not useful primarily with indicer increments of load as with STAT\_NON\_LINE.*

#### **Caution:**

*With FIXE\_PILLO, one cannot use for the loading of reference the key word FONCT\_MULT.*

#### **Caution:**

*When the loading of reference is defined by AFFE\_CHAR\_MECA\_F, this loading can be a function of the variables of space but not of time.*

### **3.12 Word**

**key**

#### **SOLVEUR**

*The syntax of this key word common to several orders is described in the document [U4.50.01].*

### **3.13 Word**

**key**

#### **CONVERGENCE**

### **CONVERGENCE =\_F**

*This key word describes the parameters making it possible to appreciate the convergence of the method of NEWTON used to solve the nonlinear mechanical problem. Operands of the key word CONVERGENCE have the same significance as in the document [U4.51.03].*

### **3.14 Word key FILING**

#### **FILING =\_F**

*Allows to file or certain results with all or certain moments of calculation. In the absence of this key word all the steps of time are filed, including the moments of calculations lately created by automatic recutting of the step of time. Operands of the key word FILING have the same significance as in the document [U4.51.03].*

### **3.15 Word key AMOR\_MODAL**

*This key word makes it possible to take into account a damping equivalent to modal damping broken up on a basis of modes precalculated in the form of concept of the mode\_meca type. This damping is taken overall into account in the dynamic equilibrium equation like one correct force with the second member - CX&.*

### **3.15.1 Operands MODE\_MECA/AMOR\_REDUIT/NB\_MODE**

*MODE\_MECA*

*= mode*

*AMOR\_REDUIT = l\_amor*

*NB\_MODE = nbmode*

*The concept mode of the mode\_meca type (entered by operand MODE\_MECA) represents the base of modes precalculated on which one breaks up modal damping. This base must imperatively to have the same profile of classification as that of the dynamic system defined by parameters of key word SOLVEUR [§3.12]. It be possible to truncate the modal base with one a number of modes defined by NB\_MODE. Failing this, one takes all the modes of the modal base.*

*Modal depreciation in reduced form is given in the form of a list of realities of which the number of terms is lower or equal to the number of modes taken into account. If the number of terms of the list is strictly lower, one extends this list with the value of its last term until its size reaches the number of calculated modes.*

### **3.15.2 Operand REAC\_VITE**

*If its value is “YES”, one modifies the correct force of modal damping to each iteration intern of NEWTON defined in the key word NEWTON [§3.8].*

*If its value is “NOT”, one updates this term only to the beginning of each step of time.*

## **3.16 Word**

**key**

### **OBSERVATION**

*This key word makes it possible post-to treat certain fields with the nodes or the elements on parts of model at moments of a list (known as of observation) generally more refined than the list of moments filed defined in the key word FILING [§3.14] (where one stores all the fields on all it model). It is used primarily for economies of storage.*

*This key word is répétable and allows the creation of a table of of the same observation name than the concept result of DYNA\_NON\_LINE.*

### **3.16.1 Operands LIST\_ARCH/LIST\_INST/INST/PAS\_OBSE**

*These operands make it possible to define in the choices a list of moments of observation. They have the same one significance that of the same operands name being used to define a list of filing. PAS\_OBSE playing the same part as NOT in FILING [§3.14].*

### **3.16.2 Operands NOM\_CHAM/NOM\_CMP**

*These operands make it possible to define the fields post-to be treated like their components given by their name (by NOM\_CMP).*

### **3.16.3 Operands NODE/GROUP\_NO**

*These operands make it possible to define the nodes of postprocessing for fields in the nodes (“DEPL”, “QUICKLY”, “ACCE”, “DEPL\_ABSOLU”, “VITE\_ABSOLU”, “ACCE\_ABSOLU”).*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

17/22

### **3.16.4 Operands NETS/NOT**

*These operands which go hand in hand make it possible to define the meshes of postprocessing and their points of extraction for fields with the elements (“SIEF\_ELGA” or “VARI\_ELGA”).*

## **3.17 Description of the diagram of integration in time**

*One can use a method of NEWMARK, HILBER-HUGHES-TAYLOR (HHT) or one TETA\_METHODE.*

### **3.17.1 Key word NEWMARK**

**/NEWMARK=\_F (**

**ALPHA**

**= /**

**0.25**

**[DEFECT]**

**/**

**alph**

**DELTA =**

**/ 0.5**

**/**

**delt**

**[DEFECT]**

**)**

*The method of integration in time is that of NEWMARK, with the values given of parameters alph and delt.*

*When neither alph is specified, nor delt, one with the method known as “regulates trapezoid” (alph = 0.25; delt = 0.5) which, into linear, is unconditionally stable and does not bring any dissipation parasite (i.e numerical damping), but which, into nonlinear, can be unstable [bib1].*

### **3.17.2 Key word HHT**

**/**

**HHT=\_F (**

**ALPHA**

**= /**

**-0.3**

**[DEFECT]**

**/**

**alph****[R]**

)

*The method of integration in time (implicit diagram of integration) is that of HILBER-HUGHES-TAYLOR (HHT) [bib1], with the negative value of alph given. More |alph| is large, more the numerical damping brought by calculation is important. But this dissipation is sometimes necessary, into nonlinear, to ensure stability (less to assign a damping by material to the structure).*

### 3.17.3 Key word TETA\_METHODE

**/TETA\_METHODE =\_F (**

**TETA**

=

/

**teta****[R]**

)

*The diagram of integration in time is an implicit theta-diagram of order 1, of speed. It can be used that with loads of contact. And in this case, it must also call upon CONTINUOUS method (AFFE\_CHAR\_MECA/CONTACT/METHOD = "CONTINUOUS") and formulation of speed (FORMULATION = "QUICKLY").*

*teta must lie between 0,5 and 1: 0,5 corresponds to a minimum of dissipation numerical, 1 orrespond with a maximum of numerical dissipation. tet = 1 allows to find the diagram of Euler.*

*19/22*

**RELI\_ITER and RELI\_COEF:** iteration count and linear coefficient of research.

**PILO\_PARA:** value of the parameter of piloting.

**LAGR\_ECAR, LAGR\_INCR and LAGR\_ITER:** parameters of Lagrangian increased (see LAGR\_NON\_LOCAL)

**MATR\_ASSE:** option of assembly for the matrix (elastic, tangent, secant)

**ITER\_DEBO:** indicate an iteration of Borst for the plane constraints or the behaviors unidimensional (see COMP\_INCR)

**CTCD\_ITER:** iteration count intern contact/friction, methods discrete. The column is marked by X as long as the contact did not converge on the geometry.

**CTCD\_INFO:** information on the state of contact for the discrete methods:

.

**ALGO:** resolution of the problem of contact (iterations intern)

.

**ALGO/REAC\_GEOM:** resolution of the problem of contact (internal iterations) and updated of geometry for reactualization

.

**INIT\_GEOM/ALGO:** initialization of the geometry for the contact and resolution of the problem of contact

.

**ATT\_PT\_FIXE:** do not make an attempt fixes for the contact discrete methods

**CTCD\_GEOM:** value of maximum displacement for the geometrical reactualization of the contact, discrete methods.

**CTCD\_NOEU:** node where the value of displacement is maximum during the geometrical reactualization

contact, discrete methods.

**CTCC\_GEOM:** number of the iteration of contact continuous method at the time of the loop on the geometry.

column is marked by X as long as one did not converge.

**CTCC\_FROT:** number of the iteration of contact continuous method at the time of the loop on the threshold of

friction. The column is marked by X as long as one did not converge.

**CTCC\_CONT:** number of the iteration of contact continuous method at the time of the loop on the state of contact

(active constraints). The column is marked by X as long as one did not converge.

**Composite types (posts several columns):**

**STANDARD:** standard posting (by defect) of the table of convergence. Contains:

The number of the iteration of Newton (ITE\_NEWT)

All columns necessary according to functionalities' activated (linear research, contact, piloting,...)

.

The value of residues (RESI\_MAXI and RESI\_RELA)

**MINIMUM: minimum posting of the table of convergence. Contains:**

•  
**The number of the iteration of Newton (ITER\_NEWT)**

•  
**The value of residues (RESI\_MAXI and RESI\_RELA)**

**Note:**

•  
**One cannot ask more than sixteen columns (16 columns of 16 characters, that is to say a width total of 256).**

•  
**The columns are cumulable: one can ask for MINIMUM posting and add one unspecified column.**

•  
**One can have several times the same column.**

•  
**As long as “X” is posted in column ITER\_NEWT, calculation did not converge. This depends of course on the value of the residues but also of the convergence of the contact or on De Borst.**

•  
**For the method of contact continues, the iterations of Newton constitutes an internal loop with three other loops (CTCC\_GEOM, CTCC\_FROT and CTCC\_CONT). ITER\_NEWT is not thus not in first position in “STANDARD” mode and it is the marking of columns CTCC\_\* who exploits the part of final Justice of the Peace convergence.**

### **3.18.3 Operand *INFO\_RESIDU***

***INFO\_RESIDU***

**=**  
**“NOT”,**  
**[DEFECT]**

**“YES”**

*This operand makes it possible to add a column for each residue evaluated (RESI\_RELA, RESI\_MAXI and RESI\_REFE). This column will indicate the node where the residue is maximum, which can help the user when there are difficulties of convergence. For example, to see whether the material were badly definite with an incorrect value on an element.*

*This option is strictly equivalent to the addition of columns RELA\_NOEU, RELA\_MAXI or RELA\_REFE when one completely describes the posting of the table of convergence but allows to post information on the nodes when one is in STANDARD” or “MINIMUM” mode “, without needing to describe all the other columns.*

### **3.18.4 Operands *LONG\_R*, *PREC\_R* and *LONG\_I***

***LONG\_R* =**

**/ 12**

**[DEFECT]**

**/**

***long\_r***

**[I]**

***PREC\_R* =**

**/ 5**

**[DEFECT]**

/

**prec\_r****[I]****LONG\_I =**

/ 6

**[DEFECT]**

/

**long\_i****[I]**

*These operands make it possible to modify the posting of information in the table of convergence. All the columns have a fixed width of 16 characters. When information is a reality, one can require a personalized posting: the length long\_r of posted reality (maximum 16) and numbers it significant figures.*

*When it is an entirety, one can regulate the length by long\_i. For a it, character string format is always of 16 characters.*

### **3.19 Operand**

**SOLV\_NON\_LOCAL**

*The syntax of this key word is identical to key word SOLVEUR describes in the document [U4.50.01]. To use for a nonlocal model.*

### **3.20 Operand**

**LAGR\_NON\_LOCAL**

*The integration of nonlocal laws of behavior imposes the resolution of a total problem (on all the structure): the minimization of a functional calculus energy (the expression of Lagrangian increased) by*

*report/ratio with a scalar nodal variable.*

*The resolution of this problem is carried out by means of an algorithm primal newton and dual BFGS compound, which consists of two phases:*

.

*Resolution of the primal problem:*

*Minimization compared to the variable interns nonlocal and its gradient (cham\_elem)*

*Minimization compared to the variable interns with the nodes (cham\_no)*

*Primal test of convergence: the largest component of the assembled residue*

.

*Resolution of the dual problem: (Maximization compared to the multipliers of Lagrange)*

*Calculation of a direction of descent BFGS*

*Linear research by method of Wolfe*

*Dual test of convergence: the largest component of the gradient*

*Reactualization of the multipliers of Lagrange*

*ITER\_PRIM\_MAXI = iterprimmax (10 per defect)*

*Iteration count maximum for the resolution of the primal problem.*

*RESI\_PRIM\_ABSO = resiprimab*

*Precision for the test of convergence for the primal problem.*

*ITER\_DUAL\_MAXI = iterdmax (50 per defect)*

*Iteration count maximum for the resolution of the dual problem.*

*Instruction manual*

*RESI\_DUAL\_ABSO* = *residabso*

*Precision for the test of convergence for the dual problem.*

*R = rho (1000 per defect)*

*Coefficient of penalization of Lagrangian increased.*

**Note:**

*as the precision of the dual problem strongly depends on that of the primal problem, one advise to choose a better precision for the primal problem, for example 100 or 1000 times more than for the dual problem.*

### **3.21 Operands**

#### ***SENSITIVITY***

*SENSITIVITY*

=

*sensitive parameter list*

*[l\_para\_sensi]*

*Activate the calculation of derived from the fields from displacement, speed and acceleration compared to a significant parameter of the problem.*

*The document [U4.50.01] specifies the operation of the key word.*

### **3.22 Operand INFORMATION**

*INFORMATION*

=  
*inf*

*Allows to carry out in the file message various intermediate impressions in the presence of unilateral contact treaty by the method of the active constraints.*

*inf =  
1 impression of the list of the nodes in contact after convergence with each iteration of Newton.*

= 2  
*idem 1 plus impression of associations/dissociations of nodes enters iterations of the method of the active constraints.*

*Other impressions are made systematically during nonlinear calculation, independently value assigned to the key word INFORMATION: they are the impressions of the residues and the increments relative of displacement during iterations of Newton.*

### **3.23 Operand TITRATE**

*TITRATE = tx*

*tx is the title of calculation. It will be printed at the head results. See [U4.03.01].*

## ***1 Goal***

***To calculate the transitory dynamic response to an unspecified temporal excitation.***

***The temporal loading must be given in the form of a linear combination of vectors forces assembled constant in time. They can be provided directly in the form of vectors assembled or in the form of loads which will be assembled in the algorithm.***

***Only the coefficients of the linear combination are a function of time.***

***The implicit methods of integration available are Wilson-theta and NEWMARK, and the methods of integration explicit available are the diagram with the differences centered, and a version with step adaptive of this same diagram.***

***Moments of filing can be specified.***

***Product a concept result of the dyna\_trans type.***

***Equations of behaviour under transitory excitation***

***The operator carries out the direct temporal integration of a transitory linear mechanical problem of form:***

$$M\dot{X} + C\dot{X} + KX = (T) F (X)$$

*I*

*I*

*I*

*O matrices M, C*

*, K*

*are the assembled real matrices of the problem finite elements (respectively) of mass, damping and rigidity of the system.*

*I are functions of time (cf DEFI\_FONCTION [U4.31.02]) and Fi are vectors assembled resulting from loadings in imposed force (cf AFFE\_CHAR\_MECA [U4.44.01]); they can to be provided directly in the form of assembled vectors or loads which will be assemblies in the algorithm.*

*The solution (X, X, & X&) is calculated on a temporal discretization Ti of the specified interval of study by the user.*

## **4 Operands**

### **4.1 Operand**

**MODEL**

**MODEL = Mo**

*Name of the model whose elements are the subject of dynamic calculation.*

*This operand is obligatory when one applies an excitation of the type charges with the key word EXCIT (cf [§4.8]).*

### **4.2 Operand**

**CHAM\_MATER**

**CHAM\_MATER = chmat**

*Name of the affected material field on the model Mo, necessary when one is applied excitation of the type charges with key word EXCIT.*

### **4.3 Operand**

**CARA\_ELEM**

*CARA\_ELEM = carac*

*Name of the characteristics of the elements of beam, hull etc, necessary when one applies an excitation of the type charges with key word EXCIT.*

#### **4.4 Operand**

**MODE\_STAT**

*MODE\_STAT = modestat*

*Name of the static mode necessary in the case of a seismic calculation with excitations multi-supports [R4.05.01].*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

*Version*

*7.4*

*Titrate:*

*Date:*

*08/02/05*

*Author (S):*

*E. BOYERE, D. GIRARDOT Key*

*:*

*U4.53.02-H Page*

*: 5/12*

#### **4.5**

**Matrices of the problem**

*MATR\_MASS = m*

*Concept stamps assembled of matr\_asse\_DEPL\_R type corresponding to the matrix of mass system.*

*MATR\_RIGI = K*

*Concept stamps assembled of matr\_asse\_DEPL\_R type corresponding to the matrix of rigidity*

*system.*

*MATR\_AMOR = C*

*Concept stamps assembled of matr\_asse\_DEPL\_R type corresponding to the matrix of damping of the system.*

*The three matrices must be based on same classification and be built with the same mode of storage.*

#### ***4.6 Diagrams of integration***

*/"WILSON"*

*Implicit diagram of integration of WILSON type.*

*Key word factor allowing to specify the parameters of integration.*

*THETA = HT*

*Value of the parameter for the method of WILSON.*

*By defect = 1 4*

*, .*

*This diagram should not be used when one imposes nonnull displacements by the intermediary of an assembled vector.*

*See [R5.05.02].*

*/*

*"NEWMARK"*

*Implicit diagram of integration of type NEWMARK.*

*Key word factor allowing to specify the parameters of integration and.*

*ALPHA = Al*

*Value of the parameter for the method of NEWMARK. By defect = 0.25.*

*DELTA = of*

*Value of the parameter for the method of NEWMARK. By defect = 0.5.*

*See [R5.05.02].*

*/“DIFF\_CENTRE”*

*Diagram of integration clarifies by centered differences. The use of this diagram imposes certain enumerated restrictions of use on [§6.3]. The theoretical description of the diagram is made in [bib 2].*

*/“ADAPT”*

*Diagram of integration clarifies with step of adaptive time, alternative of the diagram of the differences centered. The use of this diagram imposes certain restrictions of use enumerated on [§6.3] (see [bib 2]).*

#### **4.7 Key word**

##### **ETAT\_INIT**

*This functionality allows a continuation of a transitory calculation, by taking as initial state one result obtained by a preceding calculation with DYNA\_LINE\_TRAN. It also makes it possible to define initial conditions of fields type to the nodes.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

Titrate:

Operator DYNA\_LINE\_TRAN

Date:

08/02/05

Author (S):

**E. BOYERE, D. GIRARDOT** Key

:

U4.53.02-H Page

: 6/12

#### **4.7.1 Operands**

##### **DYNA\_TRANS**

*/DYNA\_TRANS = Dy*

Concept of the *dyna\_trans* type resulting from a preceding calculation with *DYNA\_LINE\_TRAN*, and defining the initial conditions for new calculation.

#### 4.7.2 Operands

##### **DEPL\_INIT/VITE\_INIT**

*/DEPL\_INIT = C*

Concept of the *cham\_no\_DEPL\_R* type, displacements initial.

*VITE\_INIT = vo*

Concept of the *cham\_no\_DEPL\_R* type, initial speeds.

#### 4.7.3 Operands

##### **NUME\_INIT/INST\_INIT**

*/NUME\_INIT = nuini*

*nuini* indicates the number of filing of preceding calculation to extract and take as state initial in the case of a recovery.

*/INST\_INIT = to*

Moment of preceding calculation to in the case of extract and take as initial state one recovery.

In the absence of *NUME\_INIT* and *INST\_INIT*, the moment of recovery is taken equal to the last moment of filed preceding calculation.

#### 4.7.4 Operand

##### **CRITERION**

*CRITERION =*

Indicate with which precision the research of the moment must be done:

“RELATIVE”: interval of research [(1-prec) .instant, (1+prec) .instant]

“ABSOLUTE”: interval of research [moment-prec, instant+prec]

The default value of the search criterion is “RELATIVE”.

#### 4.7.5 Operand

## **PRECISION**

*PRECISION* =/1.E-03  
[DEFECT]  
/  
*prec* [R]

*Indicate with which precision the research of the moment must be done.*

### **4.8 Key word**

#### **EXCIT**

*EXCIT* =

*Operand allowing to define several space-time excitations. Maybe by indicating one vector assembled correspondent with a loading, is loads which will lead to calculation and to assembly of a second member. The assembled vector can be associated a function of temporal evolution or a constant multiplying coefficient.*

*The total loading is the sum of the loadings defined by all the occurrences of the key word EXCIT (cf [§4.8.2]).*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

*Version*

*Author (S):*

**E. BOYERE, D. GIRARDOT** Key

:

*U4.53.02-H Page*

: 7/12

### **4.8.1 Operands**

#### **VECT\_ASSE/LOAD**

*/VECT\_ASSE = vecti*

*Vector assembled correspondent with a loading (concept of the cham\_no\_DEPL\_R type).*

*/COEF\_MULT = Ci*

*Multiplicative coefficient of the vector assembled vecti.*

*/*  
*FONC\_MULT*  
*= I*

*See [§4.8.2].*

*/LOAD = chi*

*chi is the loading possibly comprising the evolution of a field of temperature specified by the ième occurrence of EXCIT.*

*See [§4.8.2].*

#### **4.8.2 Operand**

***FONC\_MULT***

*FONC\_MULT = I*

*I is the multiplicative function of the time of the assembled vector or the loading specified with ième occurrence of EXCIT.*

***The CH loading and boundary conditions for N occurrences of the key word factor EXCIT are:***

*N*  
***CH (T) = (T) CH***  
*I*  
*I*  
*I = 1*

*The fields of temperature are not multiplied by I in thermomechanical analysis.*

***Important remark:***

*The boundary conditions of the displacement type imposed not no one can be imposed with an assembled vector or a load; it is then necessary to use it imperatively diagram of Newmark.*

### **4.8.3 Operands *MULTI\_APPUI/ACCE/QUICKLY/DEPL/DIRECTION/NODE/ GROUP\_NO***

*In the case of an excitation multi-supports (*MULT\_APPUI* = "YES"), the other operands have exactly same significance as in the key word factor *EXCIT* of the operator *DYNA\_TRAN\_MODAL* [U4.53.21].*

### **4.9 Key word *AMOR\_MODAL***

*This key word makes it possible to take into account a damping equivalent to modal damping broken up on a basis of modes precalculated in the form of concept of the *mode\_meca* type. This damping is taken overall into account in the dynamic equilibrium equation like one correct force with the second member - *CX&*.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

*:*

*U4.53.02-H Page*

*: 8/12*

### **4.9.1 Operands**

***MODE\_MECA/AMOR\_REDUIT/NB\_MODE***

*MODE\_MECA*

*= mode*

*AMOR\_REDUIT = *l\_amor**

*NB\_MODE = nbmode*

*The concept mode of the mode\_meca type (entered by operand MODE\_MECA) represents the base of modes precalculated on which one breaks up modal damping. This base must imperatively to have the same profile of classification as that of the dynamic system defined by parameters of key word SOLVEUR [§4.10]. It be possible to truncate the modal base with one a number of modes defined by NB\_MODE. Failing this, one takes all the modes of the modal base.*

*Modal depreciation in reduced form is given in the form of a list of realities of which the number of terms is lower or equal to the number of modes taken into account. If the number of terms of the list is strictly lower, one extends this list with the value of its last term until its size reaches the number of calculated modes.*

#### **4.10 Key word SENSITIVITY**

*SENSITIVITY = \_F (...)*

*Activate the calculation of derived from the field from displacement, speed and acceleration compared to one significant parameter of the problem.*

*The document [U4.50.02] specifies the operation of the key word.*

#### **4.11 Key word SOLVEUR**

*The syntax of this key word common to several orders is described in the document [U4.50.01].*

#### **4.12 Key word INCREMENT**

*Key word factor defining the moments of calculation.*

##### **4.12.1 Operands LIST\_INST/FONC\_INST/NOT**

*For the diagrams of Newmark and Wilson:*

*/LIST\_INST = l\_temp*

*Concept lists realities of the listr8 type.*

*List realities defining the moments  $T_i$  of calculation of the solution*

*/FONC\_INST = fonc*

*Concept of function the defining type of an unspecified variable with constant step evolution in time*

.

*For the diagrams of the centered differences and with step in adaptive time:*

*/NOT = dt*

*Indicate the step of time used by the algorithm. This key word is obligatory for diagram of the centered differences and for the diagram adaptive and nonavailable for diagrams of Newmark and Wilson.*

*For the adaptive diagram, it indicates at the same time the step of initial time and the step of time maximum used by the algorithm.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

Version

7.4

Titrate:

Operator *DYNA\_LINE\_TRAN*

Date:

08/02/05

Author (S):

**E. BOYERE, D. GIRARDOT** Key

:

*U4.53.02-H* Page

: 9/12

*This parameter must be sufficiently weak:*

.

*to allow the calculation of the static phases (which always use the step maximum),*

.

*to start the algorithm correctly.*

*It must however be sufficiently high not to penalize the whole of calculation.*

#### **4.12.2 Operand *PAS\_CALCUL***

*PAS\_CALCUL = ipas*

*Entirety usable for the diagrams Newmark and Wilson, and defining the periodicity of calculation of the solution: one carries out calculation all the urgent ipas of the function of time *fonc* or of the list of moments *l\_temp*.*

#### **4.12.3 Operands *INST\_INIT/INST\_FIN/NUME\_FIN***

*For the diagrams of the centered differences and with step in adaptive time:*

*INST\_INIT =  $T_i$*

*In the event of recovery one uses key word *ETAT\_INIT* [§4.7]: under this key word, the initial moment is recovered*

with operand *INST\_INIT* or taken equal to the last moment of filed preceding calculation.

Operand *INST\_INIT* under *INCREMENT* must thus be used only if it did not begin again there of one preceding calculation.

*/INST\_FIN = tf*

Moment of end of transitory calculation. Obligatory for the diagrams of the differences centered and with step of adaptive time.

*/*  
*NUME\_FIN*  
*=*  
*nufin*

Number of the moment of end of calculation in *LIST\_INST* (only for diagrams of Newmark and Wilson).

#### **4.12.4 Operands *VITE\_MIN/COEF\_MULT\_PAS/COEF\_DIV\_PAS/PAS\_LIMI\_RELA/NB\_POIN\_PERIODE/NMAX\_ITER\_PAS***

These operands relate to only the diagram with step of adaptive time.

*VITE\_MIN*  
*= /*  
*“NORM”*  
*[DEFECT]*  
*/*  
*“MAXIMUM”*

Method of calculation the speed of reference used to evaluate the apparent frequency.

When the denominator of the apparent frequency ( $x_n - x_{n-1}$ ) becomes weak, the frequency connect can become very high, which leads to an unjustified refinement of the step of time. To cure it, the algorithm uses the following criterion for each ddl *I*:

$x_i - x_{i-1}$   
*I*  
*I*  
*N*  
*n-1*  
*I*  
*X*  
& - *X*

*APn*

*cdp*

*Its default value is 1.3334, that is to say a reduction of a factor 0,75.*

*PAS\_LIMI\_RELA = plr*

*Coefficient applied to the step of initial time to define the limit of refinement and thus the step of minimal time:*

*T*

*= plr T*

*min*

*\* initial*

*NB\_POIN\_PERIODE = NR*

*A number of points per apparent period. It is this parameter which fixes the precision of calculation. It must*

*to be at least equal to 20; its default value (50) guarantees a satisfactory precision (order of 1à 2%) in the majority of the cases.*

*NMAX\_ITER\_PAS*

*A maximum number of reductions of the step of time per step of calculation:*

*if  $err > 1$  and  $Niter < Niter\ max$ :  $tn = cdp * tn$*

*It is by defect equal to 16, which limits the coefficient of reduction of the step to  $(1/1,33)^{16} = 102$  by iteration. *NMAX\_ITER\_PAS* can be:*

*.*

*increased to allow the step time to fall in a more brutal way,*

*.*

*decreased if the step of time seems excessively refined.*

#### **4.13 Operands**

##### **SENSIBLITE**

*SENSITIVITY =*

*Activate the calculation of derived from the field from displacement, speed and acceleration compared to*

*a significant parameter of the problem.*

*The document [U4.50.01] specifies the operation of the key word.*

#### **4.14 Key word**

##### **FILING**

*FILING =*

*Key word factor defining filing. In the absence of this key word factor, all steps of time are filed.*

*Whatever the option of filing chosen, one files the last step of time and all the fields associated to allow a possible continuation.*

##### **4.14.1 Operand LIST\_ARCH**

*/LIST\_ARCH = l\_arch*

*List entreties defining the moments of calculation for which the solution must be filed in the concept dyna\_tran result.*

##### **4.14.2 Operand PAS\_ARCH**

*/PAS\_ARCH = ipa*

*Entirety defining the periodicity of filing of the solution of transitory calculation in the concept dyna\_trans result.*

*If ipa = 5 one files all the 5 steps of calculation.*

*This operand is obligatory for the step of adaptive time, if the key word factor FILING is present. This entirety then makes it possible to calculate the interval between two moments of filing in the concept result, equal to PAS\_ARCH\*PAS. With this convention, the step of filing is always higher or equal to the maximum step used by calculation. For one moment of filing given, one seeks the moment of calculation nearest, which will be the actually filed moment.*

#### ***4.14.3 Operand CHAM\_EXCLU***

*CHAM\_EXCLU = (  
I "DEPL",*

*I "QUICKLY",*

*I "ACCE",*

*)*

*Allows to exclude filing from one or more fields among "DEPL", "QUICKLY" and "ACCE".*

*This exclusion is ignored for the last moment of calculation: the three fields are necessary for a CONTINUATION.*

## **4.15 Operand**

### **TITRATE**

*TITRATE = title*

*Titrate structure of data result [U4.03.01].*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

*:*

*U4.53.02-H Page*

*: 12/12*

## **5 Concept product**

*dyn is a produced concept of dyna\_trans type which will contain from 1 to 3 fields with the nodes for each filed moment.*

*These cham\_no has as a reference symbol:*

*DEPL: displacement*

*QUICKLY: speed*

*ACCE: acceleration*

## **6 Phase of execution**

### **6.1 Classification**

*The operator checks that the assembled matrices are built on the same classification.*

## **6.2 Continuation**

*In the event of continuation, one checks:*

*the existence in the concept of the dyna\_trans type provided moment (or sequence number) who is used as initial conditions,*

*for this moment of the existence of fields “DEPL”, “QUICKLY” and “ACCE”.*

## **6.3 Production run for the diagrams of the centered differences and adaptive**

*The use of these diagrams imposes certain restrictions of use:*

*these two diagrams require the use of a matrix of diagonal mass. A test checks that the matrix of mass was created with option “MASS\_MECA\_DIAG” of CALC\_MATR\_ELEM. In addition, the matrix of mass must be stored in line of sky,*

*there should not be other boundary conditions only blocked ddls.*

*A test checks that there are no boundary conditions of the connections type between ddls.*

*It is not either possible to impose nonnull displacements via one assembled vector,*

*for the diagram of the centered differences, one makes sure that the step of selected time checks them stability conditions:*

### ***1 Goal***

***To calculate the dynamic evolution of a structure whose material or geometry has a behavior nonlinear. They can be for example nonlinearities of material (plasticity or geometry (great displacements)) [R5.05.05]. The syntax of this order is very similar to that of operator STAT\_NON\_LINE [U4.51.03] and DYNA\_NON\_LINE [U4.53.01]. The essential difference with DYNA\_NON\_LINE is the resolution which is done by an explicit method on accelerations.***

***The dynamic evolution is studied starting from an initial state, configuration of reference, which can be produced by a quasi-static analysis (operator STAT\_NON\_LINE [U4.51.03]) or dynamics former (operators DYNA\_NON\_LINE and DYNA\_TRAN\_EXPLI).***

***The dynamic evolution can be studied in several successive work, by a continuation to be left from one moment already calculated, if a data base were defined in the profile of study of the user.***

***Product a concept of the evol\_noli type.***

### **3 Operands**

#### **3.1 Operands**

**MODEL/CHAM\_MATER/CARA\_ELEM/MODE\_STAT**

*MODEL = Mo*

*Name of the model whose elements are the subject of mechanical calculation.*

*CHAM\_MATER = chmat*

*Name of the affected material field on the model Mo.*

*CARA\_ELEM = carac*

*Name of the characteristics of the elements of hull, beam, bars, discrete cable, and elements affected on the model Mo, if necessary.*

*MODE\_STAT = modestat*

*Name of the static mode necessary in the case of a seismic calculation with excitations multi-supports [R4.05.01].*

#### **3.2 Word**

**key**

**EXCIT**

*EXCIT = \_F*

*This key word factor makes it possible to describe with each occurrence a load (requests and conditions with the limits), and possibly a multiplying coefficient and/or a type of load.*

##### **3.2.1 Operands**

**CHARGE/FONC\_MULT**

*CHARGE = chi*

*CH is the mechanical loading (possibly comprising the evolution of a field of*

*I*  
temperature) specified with the *i*ème occurrence of *EXCIT*.

Only one load can comprise the evolution of a field of temperature, which will have previously be defined thanks to key word *TEMP\_CALCULEE* of the order *AFFE\_CHAR\_MECA*.

$$FONC\_MULT = f_i$$

*F* is the multiplying function of the time of the loading specified with the *i*ème occurrence of *I* *EXCIT*.

The loading and boundary conditions for *N* occurrences of the key word factor *EXCIT* are:

$$\begin{aligned} N \\ CH &= F CH \\ I \\ I \\ I \\ &= 1 \end{aligned}$$

For the conditions of *DIRICHLET*, of course, only the specified value is multiplied by *F*.

By defect: *F* = 1.

The field of temperature is not multiplied by *F*.

7/12

### **3.2.2 Operand**

#### **TYPE\_CHARGE**

*TYPE\_CHARGE* = *tchi*

*By defect, tchi is worth "FIXE\_CSTE": that corresponds to a loading applied to initial geometry and not controlled. It can however be a function, and depend in particular time.*

*If tchi is worth "FIXE\_PILO", the loading is always fixed (independent of the geometry) but will be controlled thanks to the key word PILOTING [§3.11].*

*The loads controllable must result from AFFE\_CHAR\_MECA or AFFE\_CHAR\_MECA\_F and not to be affected key word FONC\_MULT. One cannot control the loadings of gravity, the centrifugal force, the forces of Laplace, them thermal loadings or of initial or anelastic deformations, and conditions of connection.*

*If tch is worth*

*I*

*"SUIV", the loading is known as "follower", i.e. it depends on the value unknown factors: for example, pressure, being a loading applying in the direction normal with a structure, depends on the geometry brought up to date of this one, and thus of displacements. A following loading is revalued with each iteration of the algorithm of resolution. A fixed loading is revalued only at each new moment, and only if chi depends on time (defined in AFFE\_CHAR\_MECA\_F and parameterized by the moment).*

Currently the loadings which can be qualified “SUIV” are the loading of gravity for the element of CABLE\_POULIE, the pressure for modelings 3D, 3D\_SI, D\_PLAN, D\_PLAN\_SI, AXIS, AXIS\_SI, C\_PLAN, C\_PLAN\_SI and for all them modelings THM (3D\_HHM, 3D\_HM, 3D\_JOINT\_CT, 3D\_THH, 3D\_THHM, 3D\_THM, AXIS\_HHM, AXIS\_HM, AXIS\_THH, AXIS\_THHM, AXIS\_THM, D\_PLAN\_HHM, D\_PLAN\_HM, D\_PLAN\_THH, D\_PLAN\_THHM, D\_PLAN\_THM) and the centrifugal force into large displacements (key word ROTATION in AFFE\_CHAR\_MECA).

If tchi is worth “DIDI then” the conditions of DIRICHLET (imposed displacements, conditions linear) will apply to the increment of displacement as from the moment given under ETAT\_INIT/NUME\_DIDI (by defect the moment of resumption of calculation) and not on displacement total. For example for an imposed displacement (key word DDL\_IMPO of AFFE\_CHAR\_MECA) the condition will be form:  $U - U = D$

0  
where  $u_0$  is the displacement defined by NUME\_DIDI and not:  $U = D$ .

### 3.2.3 Operands

**MULT\_APPUI /ACCE /VITE /DEPL /DIRECTION /NOEUD /GROUP\_NO**

In the case of an excitation multi-supports (MULT\_APPUI: “YES”), the other operands have exactly same significance as in the key word factor EXCIT of the operator DYNA\_TRAN\_MODAL [U4.53.21].

## 3.3 Description of the diagram of integration in time

Currently in DYNA\_TRAN\_EXPLI, only the diagram of the centered differences, one of the versions explicit of the diagram of Newmark, is available. For more detail to see the documentation of reference [R5.05.06].

## 3.4 Word

key  
**COMP\_INCR**

/ COMP\_INCR = \_F

This key word factor gathers the relations of behavior connecting of the rates of deformations to rates of constraints (incremental behavior). One can have in same calculation certain parts of the structure obeying with various incrémentaux behaviors (COMP\_INCR) and other parts obeying with various elastic behaviors (COMP\_ELAS). All the incremental relations of behavior supported by STAT\_NON\_LINE are available also in DYNA\_TRAN\_EXPLI, provided that the calculation of the matrix of mass elements concerned is envisaged. One will thus refer to the document [U4.51.11]

for a description of the relations of behavior available (operand RELATION) thus that other operands of key word COMP\_INCR.

### 3.5 Word

key

**COMP\_ELAS**

/

**COMP\_ELAS = \_F**

*This key word factor gathers the relations of behavior connecting the deformations (taken by report/ratio in an initial state of reference) and the constraints (elastic behavior). All them incremental relations of behavior supported by STAT\_NON\_LINE are available also in DYNA\_TRAN\_EXPLI, provided that the calculation of the matrix of mass of elements concerned is envisaged. One will thus refer to the document [U4.51.11] for one description of the relations of behavior available (operand RELATION) as well as other operands of key word COMP\_ELAS.*

### 3.6 Word

key

**ETAT\_INIT**

**ETAT\_INIT = \_F**

*Under this key word the initial conditions of the problem are defined. If key words **EVOL\_NOLI**, **DEPL**, and **QUICKLY** miss, one supposes that the initial state is with displacements, speeds and constraints null, and one calculates accelerations corresponding to the loading at the moment instini defined by operand **INST**. The other operands of key word **ETAT\_INIT** have the same one significance that in the document [U4.51.03].*

### **3.7 Word**

**key**

#### **INCREMENT**

*INCREMENT =\_F*

*The list of the moments of calculation defines. The operands of the key word **INCREMENT** have the same one significance that in the document [U4.51.03].*

### **3.8 Operand**

#### **PARAM\_THETA**

*PARAM\_THETA*

*=*

*/*

*1.*

*[DEFECT]*

*/*

*theta*

*For modelings **THM**, the argument *theta* is the parameter of the *theta*-method used for to solve the evolutionary equations of thermics and hydraulics (cf [R5.03.60] for more details). Its value must lie between 0 (explicit method) and 1 (method completely implicit).*

*For certain laws of behaviors, the argument *theta* is used for integration. It can take them values 0.5 or 1.*

*To refer, for more details with [U4.53.01].*

### **3.9 Word**

**key**

#### **PILOTING**

*PILOTING =\_F*

*When the intensity of part of the loading is not known a priori (loading known as of reference defined in **AFFE\_CHAR\_MECA** or **AFFE\_CHAR\_MECA\_F** with load of the type **FIXE\_PILO**), the key word **PILOTING** makes it possible to control this loading via one*

*node (or node groups) on which one can impose various modes of piloting (key word TYPE). The operands of the key word PILOTING have the same significance as in the document [U4.51.03]. However, this option also activates with DYNA\_TRAN\_EXPLI is to be used there with reserve owing to the fact that time has a physical and nonvirtual significance: it is not useful primarily with indicer increments of load as with STAT\_NON\_LINE.*

**Caution:**

*With FIXE\_PILO, one cannot use for the loading of reference the key word FONCT\_MULT.*

**Caution:**

*When the loading of reference is defined by AFFE\_CHAR\_MECA\_F, this loading can be a function of the variables of space but not of time.*

U4.53.03-B1 Page:

9/12

**3.10 Word**

**key**

**SOLVEUR**

*The syntax of this key word common to several orders is described in the document [U4.50.01].*

**3.11 Word**

**key**

**FILING**

*FILING = \_F*

*Allows to file or certain results with all or certain moments of calculation.*

*In the absence of this key word all the steps of time are filed, including the moments of calculations lately created by automatic recutting of the step of time. Operands of the key word FILING have the same significance as in the document [U4.51.03].*

**3.12 Word**

**key**

**AMOR\_MODAL**

*This key word makes it possible to take into account a damping equivalent to modal damping broken up on a basis of modes precalculated in the form of concept of the mode\_meca type. This damping is taken overall into account in the dynamic equilibrium equation like one correct force with the second member - CX&.*

**3.12.1 Operands MODE\_MECA/AMOR\_REDUIT/NB\_MODE**

*MODE\_MECA*

*= mode*

*AMOR\_REDUIT = l\_amor*

*NB\_MODE = nbmode*

*The concept mode of the mode\_meca type (entered by operand MODE\_MECA) represents the base of modes precalculated on which one breaks up modal damping. This base must imperatively to have the same profile of classification as that of the dynamic system defined by parameters of key word SOLVEUR [§3.12]. It be possible to truncate the modal base with one a number of modes defined by NB\_MODE. Failing this, one takes all the modes of the modal base.*

*Modal depreciation in reduced form is given in the form of a list of realities of which the number of terms is lower or equal to the number of modes taken into account. If the number of terms of the list is strictly lower, one extends this list with the value of its last term until its size reaches the number of calculated modes.*

**3.12.2 Operand REAC\_VITE**

*If its value is "YES", one modifies the correct force of modal damping to each iteration intern of NEWTON defined in the key word NEWTON [§3.8].*

*If its value is "NOT", one updates this term only to the beginning of each step of time.*

**Note:**

*In the case of DYNA\_TRAN\_EXPLI, there is only one internal iteration of NEWTON.*

10/12

### **3.13 Word**

**key**

**PROJ\_MODAL**

*This key word makes it possible to make calculation on a beforehand calculated modal basis.*

*MODE\_MECA = mode,*

*[mode\_meca]*

*NB\_MODE =/nbmode, [I]*

*/*

*9999,*

*[DEFECT]*

*One specifies the modal base to use (MODE\_MECA) and numbers it modes (NB\_MODE).*

**Important remark:**

*The modal base must be based on a coherent classification with that of the evolution calculated (cf [§ 3.14]): even profile of classification.*

### **3.14 Word**

**key**

**OBSERVATION**

*This key word makes it possible post-to treat certain fields with the nodes or the elements on parts of model at moments of a list (known as of observation) generally more refined than the list of moments filed defined in the key word **FILING** [§3.14] (where one stores all the fields on all it model). It is used primarily for economies of storage.*

*This key word is répétable and allows the creation of a table of of the same observation name than the concept result of **DYNA\_TRAN\_EXPLI**.*

**3.14.1 Operands LIST\_ARCH/LIST\_INST/INST/PAS\_OBSE**

*These operands make it possible to define in the choices a list of moments of observation. They have the same one significance that of the same operands name being used to define a list of filing. **PAS\_OBSE** playing the same part as **NOT** in **FILING** [§3.14].*

**3.14.2 Operands NOM\_CHAM/NOM\_CMP**

*These operands make it possible to define the fields post-to be treated like their components given by their name (by **NOM\_CMP**).*

**3.14.3 Operands NODE/GROUP\_NO**

*These operands make it possible to define the nodes of postprocessing for fields in the nodes (“**DEPL**”, “**QUICKLY**”, “**ACCE**”, “**DEPL\_ABSOLU**”, “**VITE\_ABSOLU**”, “**ACCE\_ABSOLU**”).*

**3.14.4 Operands NETS/NOT**

*These operands which go hand in hand make it possible to define the meshes of postprocessing and their points of extraction for fields with the elements (“**SIEF\_ELGA**” or “**VARI\_ELGA**”).*

**3.15 Operand****SOLV\_NON\_LOCAL**

*The syntax of this key word is identical to key word **SOLVEUR** describes in the document [U4.50.01].  
With  
to use for a nonlocal model.*

**3.16 Operand****LAGR\_NON\_LOCAL**

*See Doc. [U4.51.03].*

### **3.17 Operand INFORMATION**

*INFORMATION*

=

*inf*

*Allows to carry out in the file message various intermediate impressions in the presence of unilateral contact treaty by the method of the active constraints.*

*inf =*

*1 impression of the list of the nodes in contact after convergence with each iteration of Newton.*

= 2

*idem 1 plus impression of associations/dissociations of nodes enters iterations of the method of the active constraints.*

*Other impressions are made systematically during nonlinear calculation, independently value assigned to the key word INFORMATION: they are the impressions of the residues and the increments relative of displacement during iterations of Newton.*

#### **3.1**

#### **Equation of dynamic behaviour under harmonic excitation**

**The damping of the structure can be viscous or hysteretic [U1.01.05] [R5.05.04].**

**This operator solves the equation:**

$$\begin{aligned}
 & ( \\
 & \begin{matrix} 3 \\ 2 \\ J \\ K \\ N \\ J \\ I \end{matrix} \\
 & - J \\
 & I - \\
 & M + J C + K \{Xe\} = H (F) I
 \end{aligned}$$

$$\begin{aligned}
 & 180 \\
 & E \\
 & G (P) \\
 & I \\
 & I
 \end{aligned}$$

$$I = 1$$

**where  $K$  represents a matrix of rigidity (real or complex),**

***M***

*represent a matrix of mass,*

***C***

*represent a matrix  
of damping,*

***I***

*represent a matrix  
of acoustic impedance resulting from a formulation in  
displacement-pressure-potential,*

*P is a current point of the structure.*

### ***3.2 Damping hysteretic***

*This operator also allows to calculate the harmonic response of a structure with  
damping hysteretic.*

(  
***K***  
***I***  
***K - M) X =***  
***N***

/

*TOUT\_CHAM =*

“YES”

/

*NOM\_CHAM*

= | “DEPL”

/ “QUICKLY”

/ “ACCE”

*Choice of the fields to calculate to represent the answer: displacement, speed, acceleration or three.*

#### **4.10 Operands**

##### **SENSIBLITE**

/

**SENSITIVITY =**

*Activate the calculation of derived from the field from displacement, speed and acceleration compared to a significant parameter of the problem.*

*The document [U4.50.01] specifies the operation of the key word.*

#### **4.11 Word**

**key**

##### **EXCIT**

**EXCIT**

*Operand allowing to define several excitations. Maybe by indicating an assembled vector correspondent with a loading, is loads which will lead to the calculation and the assembly of one second member. For each occurrence of the key word factor, one defines a component of the excitation in the form  $(H(F)(G P), \text{phase})$ .*

##### **4.11.1 Operands VECT\_ASSE/CHARGE/TYPER\_CHARGE**

*Allow to define  $G(P)$  space discretization of the loading, in the form of a field with nodes corresponding to one or more loads of force or imposed movement.*

/

**VECT\_ASSE = vecti**

**Name of the concept produced by:**

**.  
operator ASSE\_VECTEUR in imposed force or imposed of  
displacement in an absolute reference frame. The amplitudes of the excitation can be  
defined in the concepts of the type charges corresponding,  
.**

**operator CALC\_CHAR\_SEISME moving imposed of displacement, speed  
or acceleration corresponding to the vector assembled in a relative reference frame: in  
this case the loads should contain only conditions kinematics (DDL\_IMPO  
of zero value).**

**/  
CHARGE = chi**

**chi name of the concept of loading specified by the ième event of EXCIT.**

**TYPE\_CHARGE = "FIXES"**

**Is there only to use the routines of the non-linear one.**

**:**

**U4.53.11-G Page**

**: 6/8**

#### **4.11.2 Operands FONC\_MULT\_C/COEF\_MULT\_C/FONC\_MULT/COEF\_MULT**

*Allow to define H (F) law of evolution, complex or real, frequency, applied to all components of the field to the node associated with this occurrence. Several possibilities are offered:*

/  
*FONC\_MULT\_C = hci*

*Name of the concept of the fonction\_C type defining a function H (F) complex of frequency F,*

/  
*COEF\_MULT\_C = aci*

*Coefficient complexes multiplying loading, independent of the loading,*

/  
*FONC\_MULT = hi*

*Concept of the function type defining a function H (F) real of the frequency F,*

/  
*COEF\_MULT = have*

*Multiplying real coefficient of the loading, independent of the loading.*

#### **4.11.3 Operand PUIS\_PULS**

*PUIS\_PULS = nor*

*Allows to define the power of the pulsation when the loading is a function of the frequency  $n_i = (2 F) \text{ nor}$ ; by defect  $n_i = 0$ .*

#### **4.11.4 Operand PHAS\_DEG**

*PHAS\_DEG = I*

*Allows to define the phase of each component of the excitation in degrees compared to one single reference of phase; by defect  $I = 0$ .*

#### **4.11.5 Notice**

*For a problem with imposed movement, one defines the blocked degrees of freedom (conditions kinematics preliminary to the construction of the cham\_no); one can then choose an excitation:*

- .  
in imposed displacement  $N = 0, = 0^\circ$*
- .  
in imposed speed  $N = 1, = 90^\circ$*
- .  
in imposed acceleration  $N = 2, = 180^\circ$*

#### **4.12 Operand**

**TITRATE**

**TITRATE = tx**

*Titrate attached to the concept produced by this operator [U4.03.01].*

***Operator DYNA\_TRAN\_MODAL***

***1 Goal***

*To calculate the transitory dynamic response of a system deadened or not in generalized co-ordinates. Calculation is carried out by modal superposition or under-structuring.*

*Not-null initial conditions can be introduced making it possible amongst other things to use the results of a former calculation.*

*The loading is given in the form of a linear combination of vectors generalized and of functions of time describing the temporal evolution of these vectors.*

*Three explicit methods of integration: "EULER", "DEVOGE", "ADAPT" (method of integration with step adaptive time), an integral method "ITMI" and a method of integration implicit: "NEWMARK" are available. The explicit algorithms and "ITMI" support calculation with taking into account of non-linearities located with the nodes of the shocks type and friction. Methods "EULER" and "ADAPT" support the taking into account of non-linearities of the fluid blade type and antiseismic device type.*

*The structure of data result contains for various moments of calculation, the results generalized and calculated forces of shock.*

*The conversion of the results generalized in physical space is possible by the operators REST\_BASE\_PHYS [U4.63.21] or for a component by RECU\_FONCTION [U4.32.03].*

*Product a concept of the tran\_gene type.*

### **3 Operands**

#### **3.1 Matrices**

##### **generalized**

***In the case of a calculation by modal recombination, the generalized matrices must be established by operator PROJ\_MATR\_BASE [U4.63.12] or by macro-order MACRO\_PROJ\_BASE [U4.63.11], starting from the same modal base.***

***In the case of a calculation by dynamic under-structuring, the generalized matrices must be established by operator ASSE\_MATR\_GENE [U4.65.04], starting from same generalized classification.***

***MASS\_GENE = my***

***Stamp of mass of the generalized system.***

***Concept of the matr\_asse\_gene\_R type.***

***RIGI\_GENE = laughed***

***Stamp rigidity of the generalized system.***

***Concept of the matr\_asse\_gene\_R type.***

***/AMOR\_GENE = amndt***

***Stamp damping of the generalized system.***

***Concept of the matr\_asse\_gene\_R type.***

*This option is not available with method “DEVOGE”.*

*/AMOR\_REDUIT = lam*

*List reduced depreciation (percentage of damping criticizes) corresponding to each mode of the system in the form of list of realities.*

*This option is not available in dynamic under-structuring because depreciation reduced must be defined for each substructure separately (operator MACR\_ELEM\_DYNA [U4.65.01]).*

*Note:*

*If the number of reduced depreciation given is lower than the number of vectors of base used in the modal base, depreciation of the additional vectors are taken equal to the last damping of the list.*

*/LIST\_AMOR = l\_amor*

*List the depreciation reduced in the form of concept listr8.*

## **3.2 Algorithms of integration**

### **3.2.1 Operand METHOD**

#### **METHOD**

=

*Choice of the numerical method of resolution.*

*In the case of a traditional calculation by modal recombination, the user has three methods of the explicit type, an integral method and method of an implicit type.*

*In the case of a calculation by dynamic under-structuring [R4.06.04], method of calculation transient on modal basis calculated by under-structuring supports all the diagrams of integration evoked except the integral method. On the other hand, method of calculation transitory on the “bases” of the substructures supports only the diagram of Euler and the diagram with step of time adaptive.*

### **3.2.1.1 METHOD = “EULER”:** diagram clarifies order 1

*This diagram supports calculation with taking into account of the whole of localised non-linearities available.*

### **3.2.1.2 METHOD = “DEVOGE”:** diagram clarifies order 4

*The diagram of DEVOGELAERE supports calculation with taking into account of the whole of not localised linearities available.*

### **3.2.1.3 METHOD = “NEWMARK”:** implicit scheme

*This diagram allows only the integration of linear problems.*

### **3.2.1.4 METHOD = “ADAPT”:** diagram clarifies order 2

*This diagram supports calculation with taking into account of the whole of localised non-linearities available. This method uses the diagram of the centered differences, the algorithm of adaptation of no time is based on the calculation of a “apparent frequency”:*

**1**

**X**

**& - x&**

**F**

**T**

**T-1**

**APt =**

**2**

***X - X***

***T***

***T-1***

***One specifies Ci after the operands specific to the method of integration per step of adaptive times. They are the operands following of the key word factor INCREMENT:***

***NB\_POIN\_PERIODE = NR***

***A number of points per apparent period. It is this parameter which fixes the precision of calculation. It must to be at least equal to 20; its default value (50) guarantees a satisfactory precision (order from 1%) in the majority of the cases.***

***VITE\_MIN***

***=***

***Method of calculation the speed of reference used to evaluate the apparent frequency. When the denominator of the frequency connects (X - X***

***N***

***n-1) becomes weak, this one can***

***to become very high, which leads to an unjustified refinement of the step of time. To cure it, the algorithm uses the following criterion:***

***X - X***

***N***

***n-1***

***1***

***(x& - X***

***N***

***& N***

***& -1)***

***V***

***F***

***=***

***T***

***min***

***AP N***

***2***

***V***

***T***

***min***

*Vmin can be calculated in two ways different according to the value from VITE\_MIN:*

*V tn*

*“NORM” = min (N)*

*( )*

*V*

*T*

*=*

*for all the degrees of freedom.*

*100*

***INCREMENT***

#### ***3.2.2.1 Operands***

***INST\_INIT/INST\_FIN***

***INST\_INIT = to***

***.***

***Methods “EULER”, “DEVOGE”, “NEWMARK”, “ADAPT”:***

***Moment of beginning of transitory calculation. In the event of recovery, one uses key word ETAT\_INIT***

***cf [§3.3]: under this key word, the initial moment is recovered with operand INST\_INIT or taken equal to the last moment of filed preceding calculation. Operand INST\_INIT must thus be used only if there is no resumption of a preceding calculation.***

•  
**Method “ITMI”:**

**Indicate the moment of beginning of simulation. When calculation in a step of time of the phase transient is required, simulation begins with  $INS\_INIT$  + “computing time from transient”**

$$INST\_FIN = tf$$

**Moment of simulation.**

**3.2.2.2 Operands**

**NOT/VERI\_PAS**

$$NOT = dt$$

•  
**Methods “EULER”, “DEVOGE”, “NEWMARK”:**

**No the time of transitory calculation.**

•  
**Method “ADAPT”:**

**Indicate at the same time the step of initial time and the step of maximum times used by the algorithm.**

**This parameter must be sufficiently weak:**

**- to allow the calculation of the static phases (which always uses the step of time maximum),**

**-  
to start the algorithm correctly.**

**It must however be sufficiently high not to penalize the whole of calculation.**

•  
**Method “ITMI”:**

**Indicate the step of time appointed for the first step of calculation (after possible passage of transient). Thereafter, the algorithm automatically manages the step of calculation according to rigidity of the structure and the zones of transition flight/shock.**

$$VERI\_PAS = \text{reference mark}$$

**Checking of the step of computing time relative to the step of time limits given in function the highest frequency of the modes of the modal base considered or bases of**

*substructures (cf [§4.2]).*

*3.3 Word*

*key*

*ETAT\_INIT*

*Key word factor which allows a continuation of a transitory calculation, while taking as initial state:*

*.*

*that is to say a result resulting from a calculation by modal synthesis preceding EXCIT (RESU\_GENE);*

*.*

*maybe displacements and speeds expressed in the form of generalized assembled vectors EXCIT (DEPL\_INIT\_GENE and VITE\_INIT\_GENE)*

*Note:*

- This functionality is not available for a calculation by transitory under-structuring without double projection nor for method ITMI.*
- At the time of a continuation, the state of adherence or shock is not safeguarded.*
- Displacements and speeds generalized must be establish by the operator PROJ\_VECT\_BASE [U4.63.13] starting from the modal base used for the matrices of rigidity generalized or by operator RECU\_GENE [U4.71.03] steady to a calculation precedent.*

### 3.3.1 Operands

**RESU\_GENE/DEPL\_INIT\_GENE/VITE\_INIT\_GENE**

**/RESU\_GENE = tran**

*Concept of the tran\_gene type resulting from a preceding calculation with DYNA\_TRAN\_MODAL.*

**/I**

**DEPL\_INIT\_GENE = C**

*Concept of the vect\_asse\_gene type, generalized displacements initial.*

**I VITE\_INIT\_GENE = vo**

*Concept of the vect\_asse\_gene type, initial generalized speeds.*

### 3.3.2 Operand

**INST\_INIT**

**INST\_INIT = to**

*Moment of preceding calculation to in the case of extract and take as initial state a recovery. In the absence of this operand, the moment of recovery is taken equal to the last moment of preceding calculation filed.*

### 3.3.3 Operand

**CRITERION**

**CRITERION**

*Indicate with which precision the research of the moment must be done:*

*“RELATIVE”: interval of research [(1-prec) .instant, (1+prec) .instant]*

*“ABSOLUTE”: interval of research [moment-prec, instant+prec]*

*The criterion is “RELATIVE” by defect.*

### 3.3.4 Operand

**PRECISION**

**PRECISION**

***3.4***

***Description of the loading: key word EXCIT***

***EXCIT***

***Key word defining the loading. This key word must be repeated time as many as there are vectors loading generalized fi. The total loading is the sum of these vectors loading.***

***3.4.1 Operands***

***VECT\_GENE/NUME\_MODE***

***The loading is taken into account in the form of vector projected on the modal basis***

***EXCIT =\_F (VECT\_GENE) or in the form of modal component EXCIT =\_F (NUME\_MODE) or both***

***at the same time.***

***/VECT\_GENE = v***

***Generalized vector allowing to describe the space distribution of the loading.***

***Concept of the vect\_asse\_gene type.***

***The generalized vectors must be establish by operator PROJ\_VECT\_BASE [U4.63.13] with to leave the modal base used for the generalized matrices. In the case of a calculation by dynamic under-structuring, the generalized vectors must be establish by the operator ASSE\_VECT\_GENE [U4.65.05] starting from the generalized classification used for generalized matrices.***

***/NUME\_MODE = nmod***

***Number of the mode of excitation of the structure.***

### ***3.4.2 Operand***

***FONC\_MULT/COEF\_MULT***

***/FONC\_MULT = F***

***Function of time (function) allowing to describe the temporal evolution of the vector loading.***

***/COEF\_MULT = has***

***Multiplying coefficient of the generalized vector (constant actual value compared to time).***

## ***3.5***

***Particular case of the seismic analysis***

***3.5.1 Taking into account of the modes neglected by static correction: key words MODE\_CORR, CORR\_STAT and D\_FONC\_\****

***During the seismic analysis of an excited mono structure, it is possible to take into account, has posteriori, the static effect of the neglected modes. In this case, at the time of the return on the physical base, them calculated relative displacements (respectively relative speeds and accelerations) are corrected by a pseudo-mode.***

***One will find the details of this type of correction in [R4.05.01].***

***Key words MODE\_CORR and EXCIT (CORR\_STAT, D\_FONC\_DT and D\_FONC\_DT2) specific to static correction a posteriori must be simultaneously present.***

***MODE\_CORR = modcor***

***Concept of the mult\_elas type produces by the macro-order MACRO\_ELAS\_MULT [U4.51.02] which corresponds to the linear static response of the structure to a unit loading of type forces imposed (constant acceleration) in the direction of the seism considered.***

*It is noted that there is as many loading case of direction of seism.*

*U4.53.21-G Page*

*: 14/34*

*EXCIT*

*=\_F (CORR\_STAT)*

*If MODE\_CORR is present, CORR\_STAT = "YES" makes it possible to take into account the contribution*

*modal correction a posteriori for each occurrence of key word EXCIT.*

*EXCIT =\_F (D\_FONC\_DT and D\_FONC\_DT2)*

*D\_FONC\_DT and D\_FONC\_DT2 are respectively the derivative first and derived seconds of time of the definite accélérogramme, in each seismic direction considered, by the operand FONC\_MULT. They balance the contribution of the modal correction a posteriori for each occurrence of key word EXCIT in order to obtain the corrections speed respectively and of acceleration on the physical basis.*

*Note:*

- The taking into account of the static correction excludes that from the multi-supports.*
- The concept mult\_elas must be based on a coherent classification of the equations (even profile and even option of renumerotation) with that of the system solved in operator DYNA\_TRAN\_MODAL.*
- With the ième occurrence of key word EXCIT corresponds the ième elastic solution of MODCOR.*

### **3.5.2 Taking into account of the multi-supports: key words *MODE\_STAT*, *MULTI\_APPUI* and *ACCE*, *QUICKLY*, *DEPL***

*In the case of a multimedia structure, in order to restore the sizes calculated in the reference mark absolute or to take into account nonlocated linearities, it is necessary to calculate the answer generalized in*

*taking into account the component of drive.*

*For more details, one will refer to the reference [R4.05.01].*

*Key words *MODE\_STAT* and *EXCIT* (*MULT\_APPUI*; *ACCE*, *QUICKLY*, and *DEPL*; *DIRECTION* and *NODE* or*

*GROUP\_NO*) specific to the taking into account of the multimedia character must be simultaneously present.

*MODE\_STAT = psi*

*Concept of the mode\_stat type produces by the order *MODE\_STATIQUE* [U4.52.14] which corresponds to (3 or 6) the .nb\_supports static modes (where nb\_supports is the number of supports who undergo a different acceleration).*

*EXCIT*

*=\_F (MULT\_APPUI)*

*If one calculates the seismic response of a multimedia structure, *MULT\_APPUI* = “YES”, one compare at every moment, the vector of absolute displacements of each point of shock considered, in order to determine if there is shock and to calculate the corresponding forces of shock. If not, *MULT\_APPUI* = “NOT”, one compares at every moment, the vector of relative displacements of each node likely to shock.*

## ***friction and fluid blade***

### ***3.6.1 Not localised linearities of shock type and friction: key word SHOCK***

#### ***SHOCK***

***This key word factor is used for the study of the response of structures (generally slim) whose displacements are limited in one (or several) (S) - not specified a priori by the user by the presence of an obstacle (the various types of obstacles available are described in documentation [U4.44.21] of operator DEFI\_OBSTACLE), another antagonistic structure or of an effect of blade fluid.***

#### ***3.6.1.1 Operand***

##### ***ENTITLE***

***ENTITLE = int***

***Heading (eight characters to the maximum) allowing to name non-linearity. If nothing is specified by the user, the heading is the name of the NOEUD\_1.***

#### ***3.6.1.2 Operands***

***NOEUD\_1/NOEUD\_2/GROUP\_NO\_1/GROUP\_NO\_2***

***NOEUD\_1 or GROUP\_NO\_1***

***Node or name of the group of node of the structure to which the condition of non-linearity relates. In the case of a non-linear calculation by dynamic under-structuring, one indicates under this key word***

***the node of shock pertaining to the first substructure (various substructures do not belong to the same grid).***

***NOEUD\_2 or GROUP\_NO\_2***

***Node or name of the group of node of the second structure to which the condition relates of non-linearity. This operand is specific to the definition of a contact between two structures mobiles.***

***In the case of a non-linear calculation by dynamic under-structuring, one specifies the node of shock coinciding with the node indicated in NOEUD\_1 (or GROUP\_NO\_1), but pertaining to second substructure.***

***Note:***

***It is checked that the groups of nodes contain well one and only one node.***

#### ***3.6.1.3 Operand***

## **OBSTACLE**

**OBSTACLE = obs**

*Name of the concept of the obstacle type defining the geometry of an indeformable obstacle or form envelope of the play between two antagonistic structures. It is produced by the operator **DEFI\_OBSTACLE** [U4.44.21].*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

**:**

**U4.53.21-G Page**

**: 16/34**

### **3.6.1.4 Operand**

**NORM\_OBST**

**NORM\_OBST = NOR**

*List of 3 realities defining the normal in the plan of cut of the obstacle, i.e. the vector **xloc**. One advises that **xloc** is the direction of neutral fibre or a generator of the structure studied.*

### **3.6.1.5 Operand**

**ORIG\_OBST**

**ORIG\_OBST = ori**

*List of 3 realities defining the position of the origin of the obstacle in the total reference mark (key word obligatory in the case of shocks between a mobile structure and a fixed wall). In the case of*

*shocks between two mobile structures, the code considers by defect that the origin is located at medium of the two nodes of shock NOEUD\_1 (or node of the GROUP\_NO\_1) and NOEUD\_2 (or node of GROUP\_NO\_2).*

### **3.6.1.6 Operand PLAY**

*PLAY = play*

*In the case of a shock enters a mobile structure and an indeformable obstacle, the operand PLAY represent:*

*·  
the half-distance inter-plans for obstacles of the type PLAN\_Y and PLAN\_Z*

*·  
the radius of the circular obstacle for an obstacle of the type RINGS*

*This key word is unutilised in the case of obstacles discretized by segments of the DISCRETE type.*

*Note:*

*The obstacle of the type PLAN\_Y or PLAN\_Z comprises in fact two plane obstacles. Thus in case where the user wishes to model the shock on a single level, not to be obstructed by the rebound of the structure studied on the symmetrical level, one advises with the user of to push back very far (cf [3.6.1.6 Figure - has]), J represents the real play between the studied structure and the obstacle.*

*Yloc*

*Y*

*play*

*J*

*Zloc*

*K*

*X*

*orig\_obs*

*m*

*no1*

*Appear 3.6.1.6 - has: System mass-arises impacting a fixed wall*

*Note:*

*The key word PLAY is not used in the case of shock between mobile structures.*

*The various cases of plays are represented in the documentation of DEFI\_OBSTACLE [U4.44.21].*

### **3.6.1.7 Operand**

**ANGL\_VRIL**

*ANGL\_VRIL = gamma*

, angle in degrees defining the angular position of the local reference mark of the obstacle in its plan.

By convention, normal **N** in the plan of cut of the obstacle, *NORM\_OBST* defines the axis **xloc** locate local. One passes from the total reference mark **X Y Z** to the reference mark of the plan of obstacle **N y Z**

**2 2** by one

product of two rotations of angles around **Z** then around transformed **y1** of **Y**.

The position of the obstacle in this plan is obtained by a rotation of angle around the direction normal **xloc** (cf [3.6.1.7 Figure - has]).

 of gimlet ANGL\_VRIL around N.

**Note:**

- *If the user does not specify anything, the angle of gimlet is calculated by the code in the case of shocks between mobile structures with obstacles of the type BI\_PLAN.*
- *With regard to the other types of obstacles, the default value of gamma is zero.*

**3.6.1.8 Operands**

***DIST\_1/DIST\_2***

*DIST\_1 = dist1*

*Outdistance characteristic of matter surrounding NOEUD\_1: no1 (or GROUP\_NO\_1).  
 Operand specific to the contact between two mobile structures.*

*DIST\_2 = dist2*

*Outdistance characteristic of matter surrounding NOEUD\_2: no2 (or GROUP\_NO\_2).  
 Operand specific to the contact between two mobile structures.*

**Note:**

- *DIST\_1 and DIST\_2 is defined within the meaning of the outgoing normals of the two solids in opposite (DIST\_1 and DIST\_2 they are > 0 bus represent the thickness of the structures studied).*
- *Because of the calculation of the normal distance from shock, the sum of DIST\_1 and DIST\_2 must to be sufficiently large compared to the supposed amplitude of the relative displacement of*

*nodes of shocks (cf [R5.06.03]).*

### **3.6.1.9 Operands**

#### **SOUS\_STRUC\_1/SOUS\_STRUC\_2**

*SOUS\_STRUC\_1 = ss1*

*Name of the substructure which contains the node of shock informing key word NOEUD\_1 (or GROUP\_NO\_1).*

*SOUS\_STRUC\_2*

*= ss2*

*Name of the substructure which contains the node of shock informing key word NOEUD\_2 (or GROUP\_NO\_2).*

### **3.6.1.10 Opérande LOCATES**

**LOCATE = reference mark**

*Specify the reference mark in which the position of the obstacle is defined.*

/

**“TOTAL”**

*The absolute position of the obstacle is defined independently of rotations and translations which the various substructures are subjected.*

/

**nom\_sst**

*Name of a substructure.*

*The position and the normal of the obstacle are given in the reference mark used to define them co-ordinates of the nodes of the substructure nom\_sst, the position and the normal finales of the obstacle being the result of rotation and the translation to which is subjected substructure.*

- If the rate of reconstitution of the static solution is lower than the value of the threshold, one advises with the user to supplement the modal base by the local modes at the points of shock which have**

*an important local flexibility.*

*· The formula is not applicable in the event of static modes (noninvertible matrix of rigidity). Calculation continues then without checking of the criteria of shock and the user is informed by it.*

### **3.8 Word**

*key*

**ANTI\_SISM**

*Key word ANTI\_SISM is incompatible with a calculation by dynamic under-structuring. It allows to calculate the nonlinear force which exists if an antiseismic device is placed between the two nodes antagonists whose names are specified by the key words (NOEUD\_1 or GROUP\_NO\_1 and*

*NOEUD\_2*

*or GROUP\_NO\_2):*

*(K - K*

*1*

*2) X*

*X*

*F*

*K X*

*+ C sign (X*

*2*

*&) X*

*D =*

*+*

*&*

*2*

*X*

*K X*

*max*

*1 + 1*

*Py*

**RIGI\_K1, RIGI\_K2, SEUIL\_FX, C, PUIS\_ALPHA and DX\_MAX**

*Parameters of the force due to the presence of an antiseismic device.*

*As example, values of the parameters for an antiseismic device of BULGE type are:*

*K1 = 6. E+06 N/m, K2 = 0.53 E+06 N/m, Py = 1200. , C = 0.07 E+05 Nm/s, alpha = 0.2 and xmax = 0.03 m (if the problem is posed in USI).*

### **3.9 Word**

**key**

**BUCKLING**

*This key word is used for the detection of possible buckling and the evaluation of the deformation residual of an element at the time of a shock between two mobile structures or a mobile structure and a fixed wall. The force of reaction at the time of a shock with taking into account of buckling can be summarized by the following diagram:*

***F***

***Flim***

***kN***

***Fseuil***

***k2***

***compression***

***Instruction manual***

***U4.5- booklet: Methods of resolution***

***HT-66/05/004/A***

***Author (S):***

***E. BOYERE, Fe. Key WAECKEL***

***:***

***U4.53.21-G Page***

***: 22/34***

*It is considered that there is buckling if the force of reaction  $F$  reaches the value limits  $F_{lim}$  defined by the user. The normal rigidity of shock after buckling  $k_2$  is then different from front rigidity buckling  $kN$ .*

*Only the operands specific to the key word BUCKLING are detailed. The other key words allow to define the places of shock and are identical to the operands of the key word SHOCK.*

***FNOR\_CRIT = flim***

***Force normal limit which involves the buckling of the structure.***

***FNOR\_POST\_FL = fseuil***

***Force normal limit after buckling which causes a residual deformation of the structure.***

***RIGI\_NOR\_POST\_FL = k2***

***Value of normal rigidity after buckling.***

***Note:***

***The calculation of shock with buckling does not allow the taking into account of the fluid blade and of the damping of shock.***

### ***3.10 Word***

***key***

***RELA\_EFFO\_DEPL***

***RELA\_EFFO\_DEPL***

***Key word factor allowing to define a relation force-displacement or moment-rotation on one degree of freedom given in the shape of a nonlinear curve.***

#### ***3.10.1 Operand NODE***

***NODE = No***

***Name of the node of the structure to which the relation relates.***

#### ***3.10.2 Operand SOUS\_STRUC***

***SOUS\_STRUC = ss***

***Name of the substructure containing the node informing the operand NODE.***

#### ***3.10.3 Operand NOM\_CMP***

***NOM\_CMP = nomcmp***

***Name of the component of the node of the structure to which the relation relates.***

#### ***3.10.4 Operand RELATION***

## **RELATION = F**

*Name of the nonlinear function.*

*The nonlinear relation is defined starting from the linear limit of behavior.*

*Note:*

*Contrary to key word RELA\_TRANSIS, there is not linear limit, the definite function under the key word RELATION is thus defined on] -, + [.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

*Code\_Aster* ®

*Version*

*7.4*

*Titrate:*

*Operator DYNA\_TRAN\_MODAL*

*Date:*

*18/02/05*

*Author (S):*

*E. BOYERE, Fe. Key WAECKEL*

*:*

*U4.53.21-G Page*

*: 23/34*

*The equilibrium equation, for the modelled structure, subjected to a horizontal acceleration of ground ax in direction X, and having terms of correction coming from non-linearities is written:*

$$Mx\ddot{x} + Cx\dot{x} + Kx = -My + F$$

*X*

*C*

*where FC is the corrective force due to nonthe linearity of the ground. It can, for example, be defined by the following relation (cf case test SDND103):*

*F (X*

*)*

*X*

$F(X)$   
*threshold*  
 $F(X)$   
 $C$   
 $=$   
 $-$   
 $)$  with, if  $X > X$   
 $() = K 1 -$   
 $. X.$   
 $X$   
*threshold, F X*  
 $0$   
*threshold*  
 $x0$

*In example Ci above, one thus imposes, under the operand RELATION the function:*

$K$   
 $F(X) = 0 X. [X - X$   
 $C$   
*threshold].*  
 $x0$

### 3.11 Word

key  
**RELA\_TRANSIS**

**RELA\_TRANSIS**

*This key word factor was introduced in order to ensure a compatibility with the preceding versions. It corresponds in fact to key word RELA\_EFFO\_DEPL of version 4. It thus allows, just like current key word RELA\_EFFO\_DEPL to impose a relation force-displacement on a degree of freedom of a node given in the form of a nonlinear function. The nonlinear relation being defined starting from the linear limit of behavior.*

*The operands NODE, SOUS\_STRUC, NOM\_CMP and RELATION have the same direction for key words RELA\_EFFO\_DEPL, RELA\_TRANSIS and RELA\_EFFO\_VITE. They are thus not detailed in this paragraph.*

### 3.12 Word

key  
**RELA\_EFFO\_VITE**

**RELA\_EFFO\_VITE**

***Key word factor allowing to define a relation force-speed on a degree of freedom of a node given in the form of a nonlinear function.***

***The operands NODE, SOUS\_STRUC, NOM\_CMP and RELATION have the same direction for key words RELA\_EFFO\_DEPL, RELA\_TRANSIS and RELA\_EFFO\_VITE. They are thus not detailed in this paragraph.***

### ***3.13 Response of mechanical systems very slightly deadened with couplings fluidelastic***

***One describes  $C_i$  below the key words specific to the calculation of the response of mechanical systems***

***linear very slightly deadened with couplings fluidelastic possibly associated with non-linearities located with the nodes of the shocks type and frictions.***

***METHOD = "ITMI"***

***This diagram of integration by integral method allows, for the slightly deadened systems, to obtain an exact response by taking account of the variations of fluidelastic forces obtained in the presence of shocks.***

***Instruction manual***

***Author (S):***

***E. BOYERE, Fe. Key WAECKEL***

***:***

***U4.53.21-G Page***

***: 24/34***

***Note:***

***This diagram of integration is not usable in continuation and does not allow calculation by***

*dynamic under-structuring.*

*The presence of the key word SHOCK is imperative even for simulations of phases without shocks known as “phases of flight”.*

*The taking into account of non-linearities of the fluid blade type was not introduced to date into diagram of integration*

*BASE\_ELAS\_FLUI = mix*

*Modal base used for calculation.*

*Concept of the melasflu type produces by the operator CALC\_FLUI\_STRU [U4.66.02] who contains the whole of the modal bases calculated for different the rate of flow definite. It key word is obligatory for method “ITMI”.*

*NUME\_VITE\_FLUI = Nvitf*

*Rate of flow retained for calculation (sequence number).*

*Allows to extract in the concept melasflu the modal base corresponding at the speed of flow retained (cf [U4.66.02]). This key word is obligatory for method “ITMI”.*

*ETAT\_STAT*

*=*

*For the systems very slightly deadened, this option makes it possible to avoid an expensive calculation of linear phase preceding the first shock. This phase, called thereafter “transitional stage” precede the establishment by a mode made up of a succession of nonlinear phases of shocks and/or of linear phases called of “flight” according to functions' of excitation of the mechanical system applied. The time of transient corresponds to a displacement equal to the play of a thrust. It can to be relatively important (50 to 100 seconds).*

*ETAT\_STAT = “YES”:* the passage in only one step of computing time of the phase allows transient.

*The passage of the transitional stage is carried out by supposing the mechanical system in “flight”. time necessary to the passage of the transient is estimated by the algorithm according to mechanical characteristics of the system in `flight '. This estimate is based on a criterion where intervene parameter PREC\_DUREE and the durations of excitations due to the turbulent efforts.*

*Note:*

*If one asks for a simulation with calculation in a step of time of the transitional stage, it will be necessary to take care to introduce one duration of sufficiently long excitation. This duration*

***must***

***to correspond to the duration necessary to the passage of the transient increased by the duration of simulation in established mode wished. This total duration of simulation will be indicated via two operands INST\_INIT and INST\_FIN under the key word factor INCREMENT.***

***ETAT\_STAT = "NOT": Simulation does not distinguish the transitory state from the established mode.***

***PREC\_DUREE = prec***

***Allows to define the precision chosen to determine the duration of the transitional stage according to formulate:***

***-***

***(***

***Ln prec)***

***T =***

***where***

***and***

***tr***

***reduced damping and the pulsation indicate respectively***

***2***

***0***

***0***

***0***

***0***

***of each mode considered. The default value of this parameter is 1%.***

**CHOC\_FLUI**

=

*Determine the treatment carried out by the algorithm during the phases of shock with respect to the forces fluidelastic.*

*By defect, variation of the fluidelastic forces in phase of shock related to the modification of rigidity and of the damping of the mechanical system (impact on the thrust) is not taken in count.*

**NB\_MODE = Nmode**

*A number of modes of the modal base retained for dynamic calculation.*

*The preserved modes correspond to increasing frequencies (first modes). If*

*NB\_MODE is not specified, one takes all the modes of the modal base of the concept of the type melasflu.*

**NB\_MODE\_FLUI = Nmodef**

*A number of modes of the modal base disturbed by the fluidelastic phenomena of coupling in phase of shock (lower than the number of modes retained for dynamic calculation).*

*The preserved modes correspond to Nmodef first increasing frequencies (first modes). If NB\_MODE\_FLUI is not specified, one takes the number of modes retained for dynamic calculation.*

**TS\_REG\_ETAB = tsimu**

*Duration of desired simulation.*

*In the case of a simulation without preliminary calculation and in a step of time of the transitional stage*

*(ETAT\_STAT = "NOT"), this duration corresponds to the duration of simulation whatever the state of*

*system enters the moments of beginning and end of simulation. Consequently one will have to ensure oneself*

*that: TS\_REG\_ETAB INST\_FIN - INST\_INIT*

*By defect, one will have TS\_REG\_ETAB = INST\_FIN - INST\_INIT*

*In the case of a simulation with calculation of the transitional stage (ETAT\_STAT = "YES"), this duration corresponds to the duration of really desired simulation when the phase of shocks is established from the numerical point of view. Consequently one will have to make sure that:*

***TS\_REG\_ETAB INST\_FIN - INST\_INIT - “time considered transitory”***

***If this last condition is not observed, the user is informed with precision of the minimum time of excitation necessary for its calculation INST\_FIN - INST\_INIT. By defect, one a: TS\_REG\_ETAB = INST\_FIN - INST\_INIT - “time considered transitory”***

### ***3.14 Word***

***key***

***FILING***

***FILING***

***Key word factor defining filing.***

#### ***3.14.1 Operand LIST\_ARCH***

***Methods “EULER”, “DEVOGE”, “NEWMARK”:***

***/LIST\_ARCH = l\_arch***

***List entirities defining the moments of calculation for which the solution must be filed in the concept tran\_gene result.***

#### ***3.14.2 Operand PAS\_ARCH***

**PAS\_ARCH = ipa**

· **Méthodes “EULER”, “DEVOGE”, “NEWMARK”, “ITMI”:**

**Entirety defining the periodicity of filing of the solution of transitory calculation in the concept tran\_gene result.**

**If ipa = 5 one files all the 5 steps of calculation.**

**Whatever the option of filing chosen, one files the last step of time and all the fields associated to allow a possible recovery.**

**By defect one files all the steps of calculation.**

·  
**Method “ADAPT”:**

**Entirety which makes it possible to calculate the interval between two moments of filing in the concept**

**result, equal to PAS\_ARCH\*PAS. With this convention, the step of filing is always superior or equal to the maximum step used by calculation.**

**With a variable step, the moments of filing do not correspond exactly to steps of calculation. The algorithm thus files the sizes with the steps of calculation closest to the moments of filing indicated by the user (in Tn on this diagram):**

**No calculation**

**T**

**Tn+1**

**N**

**No filing**

**Moments of filing**

### **3.15 Operand**

#### **INFORMATION**

**INFORMATION = imp**

**Entirety allowing to specify the level of impression in the file MESSAGE.**

**If INFORMATION: 1, one prints following information in the file MESSAGE:**

**<I> <nom of the routine where information suivantes> is written**

**If <I> <MDTR74>, one recalls that it is a transitory calculation on modal basis “traditional”, if not <I> <SSDT74> it is a transitory calculation on modal basis by under-structuring dynamics.**

:

*U4.53.21-G Page*

: 27/34

*For each obstacle:*

- *The number and type of the obstacle;*
- *The name and co-ordinates in the total reference mark of the node of shock (of the nodes of shock in the case of a shock between mobile structures);*
- *Orientation, in the total reference mark, of the normal to the obstacle;*
- *The value of the angle of gimlet;*
- *The value of the initial play;*

*And for each node of shock and each mode, the number of the mode, values of local stiffnesses of shock and the rate of local flexibility and the local flexibility. One also prints at the end, for each node of shock:*

*RATE OF RESTIT FLEXIBILITY: 9.9539E-01 is 99.53% of local flexibility;  
RATE OF RESTIT SHARP EFFORT: 1.8979E-02 is 1.89% of the sharp effort.*

*One prints these quantity overall for the whole of the modes and each mode.*

*One prints moreover:*

·  
*for each node of shock, local the flexibility reports/ratios on flexibility of shock and static flexibility minus local flexibility on flexibility of shock,*

·  
*for each mode, its participation on the deformations statics in the nodes of shock. It is worth the report/ratio of the number of conditioning of the matrix closed by the modal vector and them static deformations on the number of conditioning of the matrix of the deformations statics.*

### **3.16 Operand IMPRESSION**

#### **IMPRESSION**

*Key word factor which makes it possible to print in the file RESULT of the sizes, nonprintable by an operator of impression, such as local displacement, local speed, the forces of contact with the nodes of shock and the value cumulated on all the modes of the modal base of projection of the rate of reconstitution of the static solution.*

#### **3.16.1 Operands ALL/LEVEL**

*The key word LEVEL makes it possible to print one or more table (X) among “DEPL\_LOC”, “VITE\_LOC”, “FORC\_LOC” and “TAUX\_CHOC”. With ALL = “YES” (default value), one prints the four tables.*

#### **3.16.2 Operands INST\_INIT/INST\_FIN**

*These two key words make it possible the user to filter the impressions in each loop on the steps time.*

### **3.17 Operand TITRATE**

## **4 Phase of execution**

### **4.1 Checking on the matrices**

***In the case of a calculation by modal recombination, one checks that the generalized matrices are well exits of a projection on a common basis and with the same number of basic vectors. In case of a calculation per dynamic under-structuring, one checks that the generalized matrices are well exits of the same generalized classification.***

### **4.2 Checking and council on the choice of the step of time for diagrams EULER, DEVOGE and NEWMARK:**

***One makes sure that the step of selected time checks the stability conditions of the numerical diagram (criterion CFL):***

- in the case of NEWMARK, stability is always assured but the going beyond of the criterion can to induce a lack of precision on the result and is announced by a message; calculation continues (with the risk to produce a not very precise or false result).***
- in the case of diagrams of EULER and DEVOGE, if operand VERI\_PAS is worth "YES" (value by defect), the execution is stopped, a step of minimum time is proposed. If the operand VERI\_PAS is worth "NOT" or if it is about diagram ADAPT, a message of alarm is transmitted and it calculation continues (with the risk to produce a not very precise or false result).***

***In a transitory analysis without non-linearity, it should be taken care that the step of time is such as:***

***$dt < 0,1/fn$  for NEWMARK and DEVOGE***

***$dt < 0,05/fn$  for EULER***

***fn being the highest frequency of the modes of the modal base considered.***

**Note:**

***It is mentioned that with nonlocalised linearities the step of selected time must be sometimes very lower than this advised value.***

## 4.3

### ***Production run for method “ADAPT”:***

***The execution is stopped when the step of time reaches a minimal step equal to NOT X PAS\_LIMI\_RELA.***

#### ***Note:***

***The diagram of the centered differences does not restore in an exact way the own pulsations of one system, which leads to important miscalculations in the two following cases:***

- ***Calculation of a very great number of free periods of oscillations;***
- ***Calculation of the oscillations of a system very slightly deadened (< 10%) excited on one frequency of resonance.***

***In these two cases, it is often necessary to increase parameter NB\_POIN\_PERIODE.***

***Method “ADAPT” can be used in under-structuring.***

***The step of time can be recovered by operator RECU\_FONCTION, with following syntax:***

```
not = RECU_FONCTION (  
RESU_GENE = dynamoda  
NOM_CHAM = PTEM  
....)
```

***For more clearness, it is in fact the decimal logarithm of the step of time which is stored in concept result of RECU\_FONCTION.***

## 5 Examples of use

### 5.1 Calculation of the linear response of a system

One presents an example partial of use of a linear calculation of response with static correction.

#### # Description of the loading

```
condlim = AFFE_CHAR_MECA (MODEL = model,
DDL_IMPO=_F (GROUP_NO=' A2',
DX=0., DY=0., DZ=0., DRX=0., DRY=0., DRZ: 0.)
)
```

```
charge = AFFE_CHAR_MECA (model MODELE=,
FORCE_NODALE=_F (GROUP_NO=' B2', FX=1.0D6)
)
```

```
v_elem = CALC_VECT_ELEM (OPTION=' CHAR_MECA', CHARGE= charges)
```

```
v_asse = ASSE_VECTEUR (VECT_ELEM = v_elem, NUME_DDL=NUM)
```

#### # # Calculation of the static loading

```
modcor = MACRO_ELAS_MULT (model MODELE=, NUME_DDL= NUM,
CARA_ELEM = champcar,
CHAM_MATER= champmat,
CHAR_MECA_GLOBAL= condlim,
CAS_CHARGE= _F (NOM_CAS= "CASI",
CHAR_MECA= charges)
)
```

#### # # Calculation dynamic by modal superposition

# One projects on the first 9 modes of the base

```
MACRO_PROJ_BASE (BASE = MODES, NB_VECT = 9,
MATR_ASSE_GENE = _F (MATRIX = mass_gen, MATR_ASSE = m_asse),
MATR_ASSE_GENE = _F (MATRIX = rigi_gen, MATR_ASSE = k_asse),
VECT_ASSE_GENE = _F (VECTOR = vect_gen, VECT_ASSE = v_asse)
)
```

#### # # Response with static correction

#

```
tran_gen = DYNA_TRAN_MODAL (  
MASS_GENE = mass_gen,  
RIGI_GENE = rigi_gen,  
METHOD = "DEVOGE",  
MODE_CORR = modcor,  
EXCIT = _F (VECT_GENE = vect_gen,  
CORR_STAT = "YES",  
FONC_MULT = depl,  
D_FONC_DT = quickly, D_FONC_DT2 = gamma  
),  
INCREMENT = _F (INST_INIT= 0. ,  
INST_FIN: 0.1,  
NOT = 0.00001),  
FILING = _F (PAS_ARCH = 100)  
)
```

### ***3 Functionalities***

***Operator DYNA\_ALEA\_MODAL allows to calculate the response in the frequential field, on basis modal, of a structure subjected to an excitation represented by a matrix interspectrale (cf DEFI\_INTE\_SPEC [U4.36.02]).***

***The size excitation can be of imposed ddl type or effort associated with a ddl. It also can to correspond to sources of fluid excitation [R4.05.02].***

***The excitation can be given in form derived of a nature equal to 0, 1 or 2 (displacement, speed or acceleration).***

*L`operator REST\_SPEC\_PHYS [U4.63.22] makes it possible to restore the response in displacement or effort with the ddl “of observation” (couple node, component).*

*The matrix interspectrale modal answer thus calculated can be reintroduced in a new calculation.*

## **4 Operands**

### **4.1 Word**

*key*

**BASE\_MODAL**

**BASE\_MODAL = \_F (**

*Key word factor for the definition of the parameters of selection of the modal base of calculation.*

#### **4.1.1 Operand**

**MODE\_MECA**

**MODE\_MECA**

*= modemec*

*modemec is the concept of the mode\_meca type containing the dynamic modes.*

#### **4.1.2 Operands**

**NUME\_ORDRE/AMOR\_REDUIT**

**/NUME\_ORDRE = lordre**

*lordre is the list of the sequence numbers of the modes of the concept modemec actually taken in account in calculation. Example: (2 3 4).*

**AMOR\_REDUIT = lamor**

*lamor is the list of reduced modal depreciation corresponding to the modes selected. a many elements of the list are equal to the number of elements of lordre. Example: (0.05 0.05 0.02). This key word is usable only with NUME\_ORDRE.*

#### **4.1.3 Operands**

**BANDAGE/AMOR\_UNIF**

/  
**BANDAGE = (f1 f2)**

*The dynamic modes taken into account will be those of modemec whose frequency is in the band (f1 f2)*

**AMOR\_UNIF = amor**

*For each mode selected, damping is equal to amor. This key word is not usable that with BAND.*

*Instruction manual*

*U4.5- booklet: Methods of resolution*

*HT-66/05/004/A*

---

**Code\_Aster** ®

**S. CAMBIER, J. PIGAT**

**Key:**

**U4.53.22-G Page**

**: 5/10**

**4.2 Operand**

**MODE\_STAT**

**MODE\_STAT = mosta**

*Concept of the mode\_stat type containing the static modes necessary to calculation.*

*This key word is necessary only in the case of a seismic calculation multi-supports where the excitation*

*fact on ddl (I. E. when the key word SIZE under the key word factor EXCIT is worth "DEPL\_R").*

### **4.3 Word**

**key**

**EXCIT**

**EXCIT = \_F (**

*Key word factor defining all the parameters relating to the excitation.*

*The key words DERIVATION, SIZE and MODAL define the type of excitation.*

*Key words INTE\_SPEC, NUME\_VITE\_FLUI, NUME\_ORDRE\_I, NUME\_ORDRE\_J, NOEUD\_I, NOEUD\_J, NOM\_CMP\_I and NOM\_CMP\_J define the interspectre excitation.*

#### **4.3.1 Operand**

**DERIVATION**

**DERIVATION**

**=**

*When the size of the excitation is of imposed ddl type (“DEPL\_R”), this key word allows to describe if the interspectre excitation must be regarded as a displacement, a speed or an acceleration imposed. The user then specifies 0, 1 or 2.*

*This key word is optional. By defect, it is equal to 0.*

**Note:**

*In the case of a seismic calculation, the excitation is often an acceleration. This key word must then be equal to 2.*

#### **4.3.2 Operand**

**SIZE**

**SIZE**

**=**

*This key word makes it possible to say if the excitation is of imposed ddl type (“DEPL\_R”), imposed effort (“EFFO”), source of flow-volume (“SOUR\_DEBI\_VOLU”), source of flow-mass (“SOUR\_DEBI\_MASS”), source of pressure (“SOUR\_PRESS”) or fluid source of force (“SOUR\_FORCE”).*

*This key word is optional. By defect, it is equal to “DEPL\_R” and the excitation is of ddl type of displacement imposed in all the cases except in the case of supports represented by*

*assembled vectors (key word CHAM\_NO).*

*Instruction manual*

*Key:*

*U4.53.22-G Page*

*: 6/10*

*4.3.3 Operands*

*INTE\_SPEC and NUME\_VITE\_FLUI*

*These key words define L (be) interspectre (S) of excitation.*

*INTE\_SPEC = interexc*

*interexc is the concept of the tabl\_intsp type containing the whole of the matrices interspectrales (spectral concentration of power) of excitation. It is taken into account such as it is defined in the function associated with the concept, i.e. in particular which one does not interpret a possible folding up of spectrum.*

*For a function defined by:*

*F [F, F*

*1*

*2 ]*

*S (F) given*

*One will interpret:*

*F < F*

**S**  
**1**  
**(F) = 0**  
**F [F, F**  
**1**  
**2 ]**  
**S (F) given**  
**F F**  
**S**  
**2**  
**(F) = 0**

**If the loop of frequency [F, F**  
**1**  
**2] must be reproduced for the negative frequencies, it is necessary:**

**.**  
**that is to say to give the whole of the spectrum on the axis of realities,**  
**.**  
**that is to say to apply a coefficient 2 to the value of the DSP, possible skirting,**  
**since all calculation is linear in order DYNA\_ALEA\_MODAL.**

**NUME\_VITE\_FLUI = nk**

**nk is the sequence number if the concept tabl\_intsp contains several tables of interspectres**  
**(indexed by this parameter).**

**: 7/10**

### **4.3.4 Operands NUME\_ORDRE\_I, NUME\_ORDRE\_J, NODE, NOM\_CMP, CHAM\_NO and MODAL**

*These key words bind the terms of ( ) the interspectre (S) of excitation and the points of excitation for one modal excitation or when the parameters of the table were subscripted by sequence numbers.*

*/NUME\_ORDRE\_I = noi1, noi2.*

*NUME\_ORDRE\_J =noj1, noj2,...*

*These lists of sequence number are appairées two by two in order to determine it term of the matrix interspectrale given.*

*/NODE = list\_noe*

*This key word makes it possible to specify the nodes where the multispectral excitation will be applied. Example (N1 N5 N7).*

*For all the types of sizes of excitation, except for the sources of pressure and the sources of force, list\_noe contains as many terms as it y has couples of indices defining of the interspectres of excitation.*

*In the case of sources of pressure or sources of force, with each source is associated a dipole, i.e. two points of application.*

*list\_noe then has twice more terms than there are couples of indices defining interspectres.*

*NOM\_CMP = list\_cmp*

*This key word makes it possible to specify the components on which the excitation multispectral will be applied. Example ("CLOSE" "DRZ" "PHI").*

*These components must of course correspond to degrees of freedom of the nodes of supports.*

*In all the cases, list\_cmp has the same number of elements as list\_noe.*

*For the fluid sources, it is the ddl "CLOSE" which is excited.*

*MODAL = " NON' [DEFECT]*

*The excitation is not modal in this case.*

/  
**CHAM\_NO = list\_vass**

*When this key word is present, each support of excitation is a vector assembled definite before in the command file. list\_vass the list of the assembled vectors contains holding place of supports. Size associated exciter is "EFFO". It is recommended that the associated intensity to the effort which one imposes by this skew is given by the interspectre: assembled vector is primarily used to define a function of form support of a spectrum of power in effort. It is thus standardized.*

*This option makes it possible to affect a spectrum of power of effort on one function of form.*

*In all the cases, list\_vass contains as many terms as there is couples of indices defining of the interspectres.*

**MODAL = "NON" [DEFECT]**

*The excitation is not modal in this case.*

/  
**MODAL = "YES"**

*The presence of "YES" under this key word implies that the interspectre of excitation is regarded as a modal excitation.*

#### **4.3.5 Operands**

**NOEUD\_I, NOEUD\_J, NOM\_CMP\_I and NOM\_CMP\_J**

*These key words bind the terms of ( ) the interspectre (S) of excitation and the points of excitation when them parameters of the table were subscripted by physical data made up of the couple (Node-CMP).*

*/NOEUD\_I = ndi1,  
ndi2,...  
NOM\_CMP\_I = cmpi1, cmpi2.*

*NOEUD\_J = ndj1,  
ndj2,...  
NOM\_CMP\_J = cmpj1, cmpj2,...*

*These lists of sequence number are appairées two by two in order to determine it term of the matrix interspectrale given. The length of the preceding lists must to correspond to the number of excitations imposed on the structure.*

**NODE**  
=

*list\_noe [l\_noeud]*

**NOM\_CMP = list\_comp**

*[l\_comp]*

*These two key words have the same significance as in [§4.3.4].*

**MODAL**  
=

**“NOT” [DEFECT]**

*The excitation is not modal in this case.*

#### **4.4 Word**

*key*

**ANSWER**

**ANSWER = \_F (**

*Key word factor for the definition of all the parameters concerning the answer.*

*The three following key words describe the type of the answer.*

##### **4.4.1 Operand**

**DERIVATION**

**DERIVATION**

=

*This key word has the same direction as for the key word factor EXCIT [§4.3.1].*

##### **4.4.2 Operand**

**OPTION**

**OPTION**

=

*If this key word is specified with “DIAG”, then all the nondiagonal functions of the interspectre answer are initialized to zero without being calculated. Only the autospectres are calculated. In the contrary case (“ALL”), all the functions of the interspectre answer are calculated.*

**: 9/10**

#### **4.4.3 Operands**

**FREQ\_MIN/FREQ\_MAX/NOT/FREQ\_EXCIT/NB\_POIN\_MODE**

*These key words are used to describe the frequential discretization in which the answer will be given.*

**FREQ\_MIN = fmin**

**FREQ\_MAX = fmax**

*fmin and fmax are the two terminals of the interval of frequency. not is the minimum step of discretization.*

**NOT = not**

**fmax - fmin**

*If the values of fmin and fmax are given, not is then worth by defect*

**.**  
**100**

*If not one takes fmax the greatest Eigen frequency of the dynamic modes retained for calculation.*

**2\*fmax**

*Then the discretization covers the field [0; 2\*fmax], not =*

**.**  
**100**

*On the other hand, if not is present, one makes sure that the step of discretization of the answer is everywhere lower than step.*

**FREQ\_EXCIT =**

**/**

**“WITH”**

/

**“WITHOUT”**

*If the user gives the argument “WITH” under key word **FREQ\_EXCIT**, then the frequencies excitation are integrated into the discretization of the answer (default option). If it gives the argument “WITHOUT”, they will be ignored. This key word is put at “WITHOUT” in the event of presence key word **FREQ\_MIN**.*

**NB\_POIN\_MODE = N [defect = 50]**

*The response is refined to the place of the Eigen frequencies in order to ensure good description of the response to the place of the peaks.*

*Key word **NB\_POIN\_MODE** makes it possible to define the number of steps of frequency per frequency proper taking into account. By defect, there are 50 steps per Eigen frequency. This key word is not taken into account if **FREQ\_MIN** is given.*

*Each function of the interspectre will have by defect a mode of interpolation of the type “LINEAR” and a mode of prolongation out of the field of discretization of the type “EXCLUDED”.*

#### **4.5 Operand**

**TITRATE**

**TITRATE = title**

*title is the title of calculation. It will be printed at the head results. See [U4.03.01].*

#### **4.6 Operand**

**INFORMATION**

**INFORMATION**

=

*Specify the options of impression on the file **MESSAGE**.*

**1**  
*no impression*

**2**  
*point out the selected options of calculation.*

**Key:**

**U4.53.22-G Page**

**: 10/10**

**5 Remarks**

**of use**

**·**  
**Need for a static and standard mode of dynamic modes:**

***In the case of excitation in imposed displacement, the dynamic modes are calculated in supports blocked and the presence of the static mode is obligatory.***

***In the other cases, the dynamic modes are calculated in free supports, and the presence of one static mode is not justified any more.***

***dimension of the matrix interspectrale = a number of static modes + a number of modes dynamic taken into account.***

***Thus, for a structure with five dynamic modes, excited in displacement by two supports, dimension of the matrix interspectrale of modal answer is 7.***

***If the excitation is given in imposed force, there are not static modes and the dimension of stamp interspectrale is 5.***

**·**  
**Use of the MODAL key word under the key word factor EXCIT:**

*In the case of use of the MODAL key word under the key word factor EXCIT to introduce directly the matrix of modal response like excitation, it is necessary to give again under the key words EXCIT BASE\_MODAL and MODE\_STAT all the arguments which had been used to create the matrix interspectrale modal (nodes and ddls supports).*

## **6** *Phase of checking*

*The coherence of the data is checked:*

*.  
a number of modal depreciation = a number of modes selected.*

*.  
a number of nodes of supports equal to the component count (for the excitation).*

*.  
a number of couples of indices retained in the interspectre excitation = a number of supports or a number of points of excitation.*

*.  
in the case of sources of pressure: a number of nodes supports equal to twice the number couples of indices retained in the interspectre of excitation.*

*.  
the presence of a mode\_stat is checked in the cases of excitation by a size of the type DEPL\_R.*

*.  
fmax fmin.*

## **7 Example**

```
DYNALEA1=DYNA_ALEA_MODAL (  
BASE_MODAL=_F (  
MODE_MECA = FREQ1,  
NUME_ORDRE = 1,  
AMOR_REDUIT = 0.05),  
MODE_STAT=MODESTA1,  
EXCIT=_F (  
DERIVATION = 2,  
INTE_SPEC = INTEREXC,  
NUME_ORDRE_I = 1,  
NUME_ORDRE_J = 1,  
NODE = "PI",  
NOM_CMP = "DX"),
```

**REPNSE=\_F (**  
**DERIVATION = 2)**  
**)**

## ***Operator DYNA\_SPEC\_MODAL***

### ***1 Goal***

***To calculate the response by modal recombination of a linear structure to a random excitation. This excitation is defined in the form of interspectres of power of modal efforts. The answer is established in the form of interspectres of power of generalized displacements.***

***Each matrix interspectrale is associated a modal base for which the answer is calculated. The produced result is a concept of the tabl\_intsp type.***

**Operands**

**3.1 Operand**

**BASE\_ELAS\_FLUI**

*BASE\_ELAS\_FLUI = bef*

*Concept of the melasflu type, defines a whole of modal bases associated different rates of flow of the fluid.*

**3.2 Key word**

**EXCIT**

*EXCIT*

*Key word factor which defines the excitation.*

*INTE\_SPEC\_GENE = exc*

*Concept of the tabl\_intsp type, defines the interspectres excitation (modal efforts).*

**3.3 Operand**

**OPTION**

*OPTION = "ALL" or "DIAG"*

*Argument of the text type which indicates if one wants to calculate all the interspectres “ALL” or them autospectres only “DIAG”. By defect one calculates all the interspectres.*

### **3.4 Operand**

#### **TITRATE**

*TITRATE = title*

*Argument of the text type defining the title attached to the concept tabl\_intsp at exit.*

***Operator THER\_LINEAIRE***

### ***1 Goal***

***To solve a linear problem of thermics in stationary regime or evolutionary.***

***The thermal loading is defined by the key word CHARGES.***

***The temporal discretization of an evolutionary calculation is provided by the list of moments defined under the key word***

***LIST\_INST. This calculation can be initialized, at the first moment, in three different ways (key word TEMP\_INIT):***

- by a constant temperature,***
- by a field of temperature, definite, or extracted as a preliminary from a preceding calculation,***
- by a preliminary stationary calculation.***

***The concept produced by this operator is of evol\_ther type.***

***When a calculation of sensitivity of the result compared to a parameter is required, there is production of as many structures of data of the evol\_ther type of necessary parameters.***
